T. A. RICKARD, . . . Editor

MEXICO is always a subject of immediate interest to the mining engineer. Therefore we take pleasure in publishing the scholarly article by Mr. Robert G. Cleland that appears in this issue. Mr. Cleland reviews the history of Mexico in relation to the development of its mining industry, describing the methods established during the period of Spanish dominion. For the beautiful photographs on the four-page insert we are indebted to Mr. Frank H. Probert, Dean of the Mining College in the University of California.

DISRAELI said that there were three kinds of lies: "lies, damned lies, and statistics". We are reminded of this saying by the discrepancy between various statistics purporting to give the number of Japanese in California. As the subject is controversial, it is inevitable that the statistics should be also. In discussing the subject of Japanese immigration in our issue of October 16, 1920, we quoted, with a reservation, the statement of the State Board of Control, in California, that there were 87,279 Japanese in this State at the end of 1919. Now comes the U. S. Census and says that the number in 1920 was 71,592, as against 41,356 in 1910, an increase of 42%, as compared with the gain, within the same period, of 44% in the total population of California. Hearst says that 38,000 Japanese failed to register; he is probably wrong, but the fact remains that the people of California question the correctness of the Census figures. It would be well to confirm them officially.

LEGITIMATE journalism is hard to kill. On June 1 practically all the compositors, pressmen, and bindery workers at the plant of our contemporary, the 'Canadian Engineer', at Toronto, went on strike for a 36% increase in wages, with a reduction in working hours from 48 to 44 per week. The strike for a shorter working week was ordered from Union headquarters at Indianapolis, Indiana. Canadian workmen obeyed the order, and demanded more pay and less work at a time when the country was expecting a reduction in the cost of labor. The publishers could not meet the demand without advancing subscription and advertising rates, so they joined forces with others in Toronto in resisting the Union. Realizing that the strike might last for several weeks, the publishers of the 'Engineer' are

now producing their magazine in newspaper form; and from the first issue in the new style we have obtained the foregoing news item. The moral support of the community is behind them in their resistance to unionized tyranny. We commend our contemporary across the border for the plucky fight against international interference and dictation, and for its resourcefulness in producing the 'Engineer' as a newspaper under present conditions.

GENERAL satisfaction will be felt among members of the Institute when they learn that Mr. Frederick F. Sharpless was selected unanimously by the directors on June 24 as Secretary, in succession to Mr. Bradley Stoughton, who resigned recently. Mr. Sharpless is a native of Pennsylvania and 55 years of age; he is a graduate of the University of Michigan, and for five years (1888-1893) he was Professor of Metallurgy in the Michigan College of Mines. Subsequently he practised as a consulting engineer, and was connected professionally with several important mines in the West, notably in California. He has traveled extensively abroad as well as in his own country, and enjoys a wide acquaintance among those engaged in mining. Besides his honorable prominence in the profession and his extensive knowledge of mining affairs, he is peculiarly fitted for his new appointment by reason of having served for several years, and until now, as secretary of the Mining and Metallurgical Society of America. One effect of his appointment therefore should be to foster the most friendly relations between the Institute and the Society, and thereby to further an eventual consolidation of these two organizations. Mr. Sharpless is a Quaker, that is, he belongs to the Society of Friends; we feel sure that to him the Institute will be another society of friends, and that his record as Secretary of the Institute will be honorable and successful.

SLACKNESS is an argument that does not appeal to the average Britisher, said Mr. Thomas W. Lamont in an address at Union College, Albany, recently; and for this reason the miners, in their strike appeal to public opinion in England, have lost support. Between the miners and the operators there have been the same age-old questions as to working hours and wages that we have had in our own coal regions. The men have had good

cause for complaint in Great Britain; they faced the hardships of a reduction in wages that was heavier than the lowered cost of living. Their one great and irretrievable point of weakness was their reduced output. Figures furnished to Mr. Lamont when he was in England recently showed that the output per man shift in 1920 was nearly 30% less than it was in 1913. This policy of reduced production is condemned by Mr. J. R. Clynes, the British labor leader, in a recent issue of 'Imperial Commerce'. He draws attention to the fact that toward the end of last year, which was a time of low production in Great Britain, the highest figures of unemployment were recorded. Wage earners still clung to the belief that increased output merely adds to the gains of the capitalist class. This idea must be controverted, and no change in the attitude of the worker toward the problem of production can be anticipated until the men are safeguarded against unemployment, and until proof is given that additional output is not of greater benefit to employers than to the operative classes. The conclusions of Mr. Clynes, as coming from a Labor leader, are worthy of serious attention in this country as well as in Great Britain. Greater output, he says, would confer more benefit upon wage earners than upon any other class of the community, whereas decreased production increases the burdens of the worker and diminishes the purchasing power of his wages.

IN his address to the students at the Colorado School of Mines, which we reproduce in this issue, Mr. Fredrick Laist made a number of pertinent suggestions that are worthy of a wider audience. *Inter alia*, he drew attention to the important fact that the failure of large-scale operations, when blamed on the assumption that the results of laboratory tests did not materialize, is too often due to the circumstance that the preliminary work was planned and executed improperly. The tendency, as the manager of the Anaconda reduction works remarks, is to allow the wish to be father to the thought; the laboratory work is done under conditions that could not possibly be duplicated in practice. This is particularly true in connection with the wet metallurgy of gold and silver. Since the beginnings of cyanidation, the most absurd methods of anticipating the results of practical operation have been in vogue. A common laboratory test is to agitate the ore with cyanide solution in a stoppered bottle; the ore is then washed with an indefinite amount of water, the amount of gold in the residue being taken as an index of what may be expected if cyanidation be adopted. Another common plan is to subject the pulp of ore and cyanide solution to prolonged action in a model pebble-mill, under conditions that it would be impossible to duplicate in practice. Tests are too often made with solutions of pure water and cyanide, instead of with those that carry the normal amount of impurities found in the liquor that circulates in a cyanide plant. The consumption of cyanide is often estimated incorrectly and by means of a difference of cyanide content before and after a bottle-test in which clean

water has been used to prepare the solution, instead of working liquor; the exposure of immense areas of solution, the effect of violent agitation in the presence of excess of air, and the consumption of the cyanide that is used in dissolving a precipitant are seldom anticipated. And so it is that when results on a working scale do not approach the estimates of extraction, the excuse is made that laboratory tests seldom agree with full-scale operation; and another blow is dealt at scientific research.

WE refer elsewhere to the amenities of 'discussion'. In this issue there appears a short note, from Mr. S. H. Raine, that calls for further comment, because otherwise it might leave an impression that we accept his friendly jibe that the criticism of 'experts' in apex suits is the "favorite indoor sport" of our editorial staff. On the contrary, we are engaged in serious work and not the least is an effort to bring about reform in the methods of mining litigation. The editorial opinion of the decision in the Tom Reed v. United Eastern case appeared in our issue of May 14. Our Mr. Parsons wrote an article that was partly in disagreement with that editorial, and it was interesting for that reason among others. Our policy is to encourage the ventilation of individual views on controversial subjects. Mr. Raine admits that "the law is inadequate", then let him bring forward a helpful suggestion, as we have, more than once. The article by Mr. Parsons has been justified not only by its intrinsic merit but by the fact that it has elicited a courteous and useful rejoinder from Mr. Burch. Mr. Raine concludes his note by suggesting that we give "the subject a rest" unless we can "suggest a practical remedy". We refer him to our issue of May 14 and May 28 of this year. In the latter we refer to Mr. D. W. Branton's suggestion, as in our issue of August 28, 1920, we discuss the matter apropos of the interview with Mr. Burch. Our issue of April 24, 1920, contains an editorial on 'Geologists in the Courts', and in it we make sundry proposals. When Mr. Raine has read these we shall be glad to hear from him again, for we feel assured that he can help forward the purpose in hand.

Discussion

The pages set aside for 'discussion' constitute an important part of the 'Mining and Scientific Press'. We can readily suppose that, to many, it is the most interesting portion of our paper. In the first place, the average man likes to get the views of various people instead of the opinions of one person, such as the Editor. To a member of the congregation there is something piquant in the sight of one in a neighboring pew arising to controvert the minister in the pulpit—not that we suggest a close simile, for we editors claim no heaven-sent mandate, much less a celestial inspiration for our sayings. In any event, the average reader is given the editorial views on current topics so frequently that he can almost anticipate the stand that may be taken on a given subject, whereas the opinions of his fellow-readers have a variety and

vagraney that gives them the charm of the unexpected. Frankly, the editor finds them interesting and is glad to have them, especially if they express disagreement in a form permitting of publication. We receive numerous letters of approval and endorsement, of course, but we rarely publish such letters because they are not interesting to other readers; they are like the recommendation brought by the office-boy from his mother, they are interesting only to the family. On the other hand, when a reader objects to some editorial utterance, and gives reasons for his objection, we know that such a letter will be read with keen interest, because, among other reasons, the average engineer, whom we suppose now and always to be an intensely human and altogether intelligent person, likes to see a 'kick' recorded and to feel that thus he also is represented in the forum of public opinion. However, there is an even better reason for placing a high value on the 'Discussion' columns: they enlist the assistance of the busy men, usually the very ones whose ideas are most dynamic. For example, in this issue the subject of 'Valuing Partly Exhausted Mines' is discussed by Mr. Milnor Roberts, Dean of the School of Mines in the University of Washington, and one of the leading mining engineers of the Pacific Coast. 'The Rehabilitation of the Russian Mining Industry' is the subject of a timely letter from Mr. T. J. Jones, a Californian engineer prominently connected with the Kyshtim and other important copper-mining enterprises in Siberia. Mr. Albert Burch, who needs no description, contributes a criticism of the article by Mr. A. B. Parsons on 'Mining Litigation and Common Sense', making a useful suggestion for improving the method for trying apex suits. Our friend and former associate editor, Mr. F. H. Mason, sends a note on the 'Coloring of Glass', in reply to the recent letter on this subject from Mr. Francis Drake. It will be acknowledged that discussion on such subjects by men so well qualified is an honor to technical journalism, and we accept it as such. Recently the volume of discussion has been unusually large, and we hope it may continue to maintain a vigorous amplitude, as well as good quality. We take an opportunity of thanking our friends the prospectors for their response to our invitation to 'chip in'. In a measure it is the duty of members of the profession to contribute corrections or confirmations of important statements on technical subjects in which they are versed—and more particularly corrections, for an error is hard to overtake if it gets a good start. The editors, of course, keep a watchful eye on unintentional blunders appearing in the text of the manuscripts sent to them, but such errors are of less importance than the larger ones of fact or inference that are inevitably present occasionally in a large mass of technical writing. Criticism, frank and fair, is the very life of technical journalism, particularly of the kind devoted to the interests of a specific profession: therefore we welcome contributors to 'Discussion', especially when they find reason to disagree with the Editor or his associates. In these days of deflation and depression, when mining affairs are moving at a rate that musicians de-

scribe as *piano*, but not *piuissimo*, it may be that some of our friends have time to sit down and read with more than customary deliberation. This is a good time for revising current theories and accepted ideas, as well as for incubating new ones. Gentlemen of the profession, we shall be glad to hear from you.

Influence of Metallurgic Methods on Gold Production

In these days of declining gold production it is interesting to review the metallurgic methods in vogue at the premier gold-producing centre of the world, in accounting for the tenacity with which Johannesburg has retained the lead for so many years. Conditions have been favorable, the deposits are large, and are distributed in a manner favorable to centralized control. Another important influence is seen in the advantages that accrue from friendly rivalry between the staffs of a large number of companies, all of which are working in the same district and on ore of practically the same character. No disguise of technical results is possible: operating expenses are reduced to a low level; metallurgic losses are compared, with much gain to all concerned. Furthermore, the statements of results conform to a uniform plan that aids comparison and gives the information in a direct and straightforward manner. The statistics in the annual reports permit an accurate accounting of the results at various phases of the metallurgic operations: the final estimate is made on the basis of the yield of gold, as well as upon a comparison of assays—a practice that in many cases proves, incidentally, the accuracy of the sampling and assaying methods in vogue. It is unfortunate that the reports of operations at some of the important reduction works in this country show no uniformity of presentation; in many cases it is no easy matter to determine the actual outcome of the work or to make comparison of the efficiencies of different processes. This is due largely to the custom of reporting the metal contents of ore, of intermediate products, of tailings, and of residues in terms of the national currency. In South Africa all the companies use the pennyweight (dwt.) and decimal fractions as the unit of gold content; here, the troy ounce has been adopted for use in all statistics relating to gold and silver bullion, but the dollar is frequently taken to represent the *amount* of gold and silver in the material under consideration. In attempting to justify the practice of confusing currency units with weight of metal we are accustomed to refer to the 'assay-value' of an ore. A statement to the effect that a gold ore has an 'assay-value' or even a 'value' of \$1 is an example of current phraseology that is lamentably deficient in logical justification. However, the custom is deep-rooted, and its persistence appears to be inevitable. The disadvantage is that in many instances this method of appraisal fails to give the information desired. A residue sometimes contains a proportion of silver in economic amount sufficient to warrant calculation, and the 'value' is estimated on the basis of the average price

received for silver throughout the year. The selling price of silver has varied considerably in the recent past; it will doubtless fluctuate in the near future. Whether the selling price of gold will also vary will depend on governmental action or inaction. Suffice to say that at some future date, when the re-treatment of what are now considered as valueless residues is being considered, some additional calculating will be necessary—if no more information is available than the 'assay-value' in terms of dollar currency—to determine the metal content of the dumps or other rejects from former operations.

The recording of metallurgic results in terms of troy weight makes it easy to review, with added interest, the economies of the Rand. At the Witwatersrand Gold Mining Company's plant, for example, we learn from the annual report that 416,200 tons of ore was treated during the past year. This was reduced by stamps and tube-mills to a size suitable for amalgamation and cyanidation. The gold in the original ore (as determined by amalgamation yield plus the gold-content of the resultant tailing) was 5.807 dwt.; after amalgamation it assayed 1.597 dwt. The sand, representing about 60% of the tonnage, was then leached; it carried 2.099 dwt. before treatment and 0.333 dwt. afterward. The slime, treated by the usual method adopted on the Rand, contained 1.118 dwt. before treatment, and 0.183 dwt. afterward. Such a concise statement of metallurgic results renders it easy to re-calculate the figures in terms of percentages, and to visualize the minute amount of precious metal present, in proportion to the quantity of valueless material, both before and after treatment. It is then found that the ore entering the plant contains less than one-thousandth of 1% of gold; when discharged, the average residue contains less than one-half of one ten-thousandth of 1%—0.000046%. These figures convey some idea of the amazing success of the cyanide process when operated on a scientific basis; they compel attention to points of economic and metallurgic detail that, in view of the general decline of gold production, should be accorded careful study. The first important fact is the comparative poverty of the ore. Economical treatment is essential; all-sliming is avoided, the total milling, amalgamating, and tube-milling costs amounting to 2.676 shillings per ton, which is about 53 cents at the present rate of exchange, and considerably less than when crushing and grinding to a slime are practised. Amalgamation plays an important part in the scheme of treatment on the Rand, about 72% of the total gold in the ore being recovered by this method at the Witwatersrand mill. The ratio of stamps to tube-mills (215:4) in this particular instance is also noteworthy, as indicating a tendency to retain, so far as possible, the fundamentals of the early practice of plain stamping and amalgamation.

The pulp after amalgamation is exceptionally low-grade (1.597 dwt. per ton). Conditions are highly favorable for the production of a low average residue (0.269 dwt.) after cyanidation. The pulp is classified, the major proportion of the sand being leached by the

gravity method. Two features may be emphasized: the comparative fineness of the grains that comprise the charge—it is not usually realized that an exceedingly fine but slime-free sand can be leached successfully—and the homogeneity of the mass. Leaching is a cheap and simple process; a large volume of ore, as sand, can be impoverished of its gold at little expense above that incurred by the operation of a pump and the consumption of chemicals. The metallurgic efficiency of leaching has been amply demonstrated in connection with copper practice as well as in the treatment of gold ores. Another important factor is that the loss in dissolved metal (so far as can be ascertained, and assuming that all the undissolved gold in the residue has avoided dissolution and re-precipitation) is more or less in proportion to the grade of the solution in contact with the ore when displacement, with weaker solution or water, is commenced. After efficient amalgamation in the plants of the Rand, the pulp, as well as the resultant cyanide solution, is low-grade; the dissolved loss, therefore, is small, often negligible. The major loss is in the form of undissolved gold, against which must be credited the saving in the cost of grinding, to produce a maximum of fine sand rather than a maximum of slime. In the case of the Witwatersrand company's operations, the total loss of gold per ton in the residue of classified slime is no more than the dissolved-gold loss per ton in the total residue of the United Eastern plant in Arizona, where all the ore is reduced to a slime, where the pulp contains a large proportion of crystalline grains, but where preliminary amalgamation, apparently, is impracticable, or was disregarded in the original plan, for economic reasons. No actual comparison is possible, of course, but the advantages to be gained, wherever practicable, by impoverishing the ore by amalgamation and before cyanidation appear to be obvious. Thanks to the recognition of this important metallurgic principle, the Homestake mine continues to treat, with considerable success, an exceptionally low-grade ore, and aids in maintaining the remarkably uniform production of gold from South Dakota, in contrast to the decline that has occurred in practically all the other States of the Union. The work at the Alaska Juneau property, in Alaska, is another indication that initiative, confidence, large-scale operation, and a realization of economic conditions are the fundamentals that will ensure an increased production of the precious metal in this country, and from the low-grade deposits. In considering a scheme for the treatment of gold ore, due consideration should be paid to a process that will make a financial success of the beneficiation of ore of the lowest average that can be mined; selective mining is expensive—it costs gold; the rejection of low-grade ore results in waste of gold. The subject is one of vital national concern at the present time. In view of the economic and metallurgic success that has attended large-scale leaching and concentrating operations during recent years, a new departure may be made when similar methods are applied more generally to the treatment of low-grade deposits of gold ore in the United States.

Assessment Work

The Editor:

Sir—We hope you will use every means to kill the bill recently introduced in Congress by Senator Bursum of New Mexico. For the sake of a languishing industry, for the prospector, miner, millman, and mining engineer this bill should not be allowed to pass. Through our Institute, through other societies, and through Mr. Hoover we desire to voice our protest.

ALGERNON DEL MAR,
CHARLES V. CRAIG.

Nayarit, Mexico, June 2.

Valuing Partly Exhausted Mines

The Editor:

Sir—The recent articles by Mr. Morton Webber on this subject, together with the editorial comments on them, are very interesting both on account of the valuable information they contain in clear and emphatic form and also because they bring forward the importance of the human element in mine valuation. The subject is one that cannot be reduced to formulas nor proved in every particular. In spite of man's best technical efforts he remains in the dark as to what might have been found by deepening mines that apparently failed at certain levels, but this fact need not deter us from establishing principles for mine valuation. Already devices are being tried that may yield information regarding ground beyond the workings.

To secure full and reliable information concerning an old or idle mine is often a hard task, as Mr. Webber points out. The difficulty of obtaining the general facts regarding former operations is in part unavoidable, since it is inherent in the nature of mining, especially that which has taken place in distant localities. As to records, omissions of the past cannot be helped, but we can at least combat the tendency to discard anything and everything that savors of the past. The way can be smoothed for the coming generation, and perhaps for ourselves in later years by keeping more thorough maps, sections, accounts, and statistics and also by making the mine show its own historical record in the form of specimens. A collection made as the mine develops can be made to show typical examples of the wall-rocks and the ores in their various phases and modifications from the outcrop to depth. Such a collection is always convenient for reference and some day it may prove invaluable. Too often an interesting piece of ore that might yield an important clue to an expert finds its way to the curio cabinet of some stockholder rather than to a well-

arranged working collection at the mine. A visiting engineer has enough to do when examining a property as a whole and studying its most vital parts without having to make a search of the surface and the old workings for type specimens of the ores of bygone days.

The plan of dividing proposed expenditures for development into stages, with an estimate of the cost of each step, appeals to engineers and to men experienced in promoting or backing mining operations, but does not always strike the fancy of the investing public, which needs constant education on this point. Many investors if told that they might have to wave good-bye to their first stake in a certain mine, and worse still their second, would lose interest in the scheme before it started. At the convention held in Vancouver, B. C., in 1919, Mr. Rickard in his address* pointed out clearly that the history of mining shows it to have been an adventure for capital rather than an investment.

An additional cause may be mentioned that has accounted for the closing of some mines in the rugged regions of the North-West, especially in the early stages of mining. It applies to properties situated in distant localities where transportation is difficult or costly, and the case may be summarized as one in which a mine rises and falls with a district. Such a mine will bear watching. To illustrate: An out-of-the-way camp may have a period of prosperity covering a few seasons when roads are in order, a public transportation system is operating, supplies are available, general stores are open, men are on hand, and conditions in general are easy. Sooner or later the weaker prospects fade out, the drifting population leaves the camp, and work is concentrated on one or two claims, resulting perhaps in a going mine. But the common carrier when dependent upon a mere handful of people fails to meet expenses and ceases to operate. A hard winter comes along and the 'Lone Hand' mine is forced to shut down, temporarily it is hoped. But when the snow has gone, the road is found to be greatly damaged. The mine-owners hesitate to risk the whole burden of opening the camp, and a likely mine remains idle. In later years another period of interest in the district, called by one old prospector a 'spasm', may permit the fortunes of the Lone Hand to rise with the general prosperity of the camp.

An entirely new chapter may be suggested with the title, 'Examining Mines Partly Exhausted by Nature', referring to operations in deposits that have been partly removed by erosion. This case is common in many north-

*M. & S. P., April 19, 1919. 'Mining: An Investment, a Speculation, or a Gamble?'

ern regions and in the high altitudes, especially in glaciated areas. Although the condition is due to geologic forces rather than to past mining, the result is so nearly the same and the case contains so much of human interest that it deserves a place in the discussion. The fact that an ore deposit was formed at a depth of thousands of feet below the surface then existing, and that the overlying rock has since been eroded, leaving the ore exposed at the present surface, seems to many persons connected with mining to be a difficult idea to absorb. The small proportion of such cases that the average engineer is called upon to examine, and the lack of general realization of the great speed with which glaciers and debris-laden streams perform erosion, partly account for the failure to recognize the condition described, but, whatever the reasons, the fact remains that it commonly receives little attention.

In the Pacific North-West and in the mountains northward through British Columbia and Alaska are found many orebodies exposed at the present surface in canyons and on valley-walls, yet bearing every mark of origin at moderate or great depths. Sulphides at the actual surface are not uncommon. Here Nature has done a vast amount of preparatory work for the prospector by removing thousands of feet of rock-covering from an ore deposit. She may even have done preliminary development and cut into the upper portions and outer edges of the mineralized area, which is most fortunate for man. Often, however, erosion has progressed to a stage corresponding to the working out of the upper levels of a mine, for the upper portion of the deposit and the country-rock enclosing it have been wholly removed, leaving the orebody exposed at its heart. In this case the mine-dump, that useful indicator mentioned by Mr. Webber, is rarely present in such amount as to be a gauge of quantity removed, although qualitative evidence is found in such forms as placer gold occurring in gulleches where it has accumulated from veins in the adjacent hills, or as float lying in the talus and moraines of glaciers.

Now as to the mine-valuer's interest in the case: When he inspects a prospect showing unaltered chalcopyrite at the outcrop of a vein occurring in a granite batholith at the foot of a canyon-wall, with granite cliffs towering above for thousands of feet, the total lack of an oxidized zone in the vein is evident. But on a developed mine in a corresponding situation the unusual nature of the surficial ore may be less noticeable, especially if, as often happens, the mine is opened by an adit started at a convenient point, while the outcrop occurs on some almost inaccessible cliff, or is covered by a snowbank, or is worked out. The attention of the men on the ground is centred on the lower workings, without thought of the history of the mine's early development. The fact that the wide and strong outcrop showed sulphides glistening under the blue sky is forgotten, or its significance has become dimmed. The position of the present workings with reference to the outlines of the ore deposit as it was originally formed, is not emphasized, and is commonly

overlooked, with the result, to summarize briefly, that the orebody is assumed to have an average chance of depth below its present outcrop, whereas the outcrop in a typical case really exposes the orebody at its heart.

Seattle, Washington, June 14. MILNOR ROBERTS.

Rehabilitation of the Russian Mining Industry

The Editor:

Sir—Many articles have appeared in the public press recently, most of them doubtless from inspired sources, but all foreshadowing some kind of political change that might bring about a condition favoring the safe employment of foreign capital for the resuscitation of industry and the profitable development of the vast resources of Russia. It seems as if the present so-called government has at last realized that there is no way out of its difficulties other than by a return to old-fashioned co-operation between capital, brains, and man-power. Lenin and his associates are grasping around in the darkness of their world isolation for some practical method of bringing this about. This, of course, is a political question, and it is not my purpose to discuss how it will be accomplished except to express the opinion that definite action may be anticipated, and that soon it will be possible to regard Russia as the greatest field for industrial and mining development the world has ever known.

There is a general impression abroad that so much destruction has been wrought and the economic life of the country dislocated so completely that a return to pre-war conditions must, even under the most favorable auspices, require a very long time for its consummation. I have heard men say that it would take twenty years to restore business and industry, after all existing barriers were removed. There is also a general impression that Russia in pre-war days was, on account of great distances, lack of rapid transport, rigors of climate, and the lassitude of its people, a slow and tedious country in which to work. Any engineer who has had the supervision of mining or industrial development in Russia will, I think, bear me out in the statement that both these impressions are erroneous. All sources of information agree that the destruction of property, especially of industrial plants, has been small. It is well known that, though some of the industrial centres have changed hands many times during the past four years of civil strife, the mills and factories are still standing. They suffer only from lack of usage and repair. The condition of the railways, so far as trackage, bridges, and other fixed property are concerned, is reported, by American engineers who have traveled over them within the past year, to be good. Russia and Siberia, with an area approximately four times that of the United States, has less than one-fifth as many miles of railway; but it has a far greater mileage of navigable rivers upon which traffic could quickly regain its former importance. The steamers and barges were all built in Russia, and from domestic material.

Outside the great centres of population the economic

life of the people has more or less adapted itself to existing circumstances. In many districts a general revival of the ancient home industries has provided linen and woollen cloth, leather, felt, and other necessities. There is a general reversion to the primitive life of a hundred years ago. The desire for commodities of modern life, however, and the willingness to work for them if opportunity were afforded still remain. It is certain that the mass of the people is ready and anxious for the employment that would enable them to live as they did before the War.

No difficulty would arise and no time would be lost in the rehabilitation of industry on account of labor. In all of the building trades, the Russian workmen were highly skillful. Their slow and primitive methods made it necessary to employ larger numbers than is usual in this country, but remarkably rapid progress on all kinds of construction work was the rule. Large operations in Russia were generally much more self-contained and independent in the way of facilities for construction and repair than in almost any other country. A copper mine, for instance, had its own foundry and machine-shops, where not only repairs of every kind were done, but where a large part of the mechanical equipment was designed and built. Special alloys of steel were made. Electrical equipment of all kinds, including generators, motors, and transformers, were built on the property. Structural steel such as is needed for head-frames, buildings, and traveling cranes were fabricated from sections that were rolled in the district. The Russian staff included some of the best mechanical and electrical engineers to be found anywhere; there were artisans of every kind, with a skill and pride in their work comparable to that of any country. The great majority of these people are still in the country and would be available.

Generally speaking, the only arguments for the success of industry in Russia were, and again will be, capital and organizing talent. The Russians of the intelligent class were capable and brilliant in many respects, but inherently weak in the matter of organizing ability. Foreign companies commenced their operations with specialized heads of departments from abroad, but usually found that in a year or two these could be dispensed with, without detriment to the business. The situation in Russia is, of course, bad, but it is far from hopeless; estimates of the time that would be required for the resuscitation of industrial activity can easily be exaggerated.

Mining Litigation and Common Sense

The Editor:

Sir—Mr. Parsons, in his discussion on 'Mining Litigation and Common Sense', indulges in the favorite indoor sport of the editorial staff of your journal.

No good purpose is served, so far as I can see, in criticizing the geologists and engineers who appear as expert witnesses. *They did not make the Law.* As a matter of fact, they all agree that the law is inadequate;

that the system is wrong; that it does not, and cannot, cover situations which have arisen in the past or which will arise in the future.

I have observed that a mining company, unfortunate enough to have an apex suit on its hands, seems to be perfectly willing to retain the best talent in the country to help it out of its difficulty. This is really good business on the part of said mining company.

If you are unable to suggest a practical remedy for the law itself don't you think it would be good sportsmanship to give this subject a rest?

Butte, Montana, June 13.

S. H. RAINE.

The Editor:

Sir—The article by Mr. Arthur B. Parsons in your issue of June 11 shows the results of much study and thought by an amateur. He starts with an assumed premise that decisions in mining cases should be based upon common sense, whereas the fact is that such decisions must be based upon the law and the evidence, no matter how much they may conflict with anyone's definition of common sense.

Just how far the mining law of the United States departs from a sane man's definition of common sense is evidenced by the constant efforts during the past few years of such organizations as the A. I. M. & M. E. and M. & M. S. of A. to obtain a revision of the law. Those who have been classified by Mr. Parsons as geologists, mining geologists, and court geologists have been among the leaders in this movement because they realize better than any amateur can the difficulties encountered in the administration of the existing law. But so long as the law exists it must be enforced and probably 'court geologists' will continue to be called upon to assist the courts in arriving at their decisions. How some of the judges view the law was tersely put by a Federal judge many years ago when he said: "As long as I am called upon to administer this iniquitous law I must find in favor of the plaintiff".

But a judge must do more than decide in accordance with "this iniquitous law", he is also bound to decide in accordance with the evidence, and whenever he departs from this rule and goes outside the evidence for facts, common sense or otherwise, to support his decision, he is quickly over-ruled by a reviewing court. The particular point cited by Mr. Parsons in the decision of Judge Bollinger was gained from the evidence, and not the evidence of a 'practical' man either, but that of a very clever mining geologist. It would be manifestly improper for me at this time to express any opinion as to whether both the law and the evidence tend to support his decision upon that point, and I will therefore refrain from doing so.

Coming now to the question of testimony by 'practical' men, one must first find a definition of the word 'practical' as used by Judge Bollinger and determine whether a 'court geologist' may not also be 'practical'. Evidently Judge Bollinger thought so, for as I remember the trial of the case, there was almost no testimony given

on structural questions (which were the governing points) except by the geologists and mining engineers.

If by 'practical' Mr. Parsons means the honest practical miner, I have no quarrel with him, for the testimony of such a man is entitled to great weight. But in this world of competitive effort the practical miner who used to be frequently employed in mining litigation has been almost entirely eliminated, and the reasons are not far to seek. In the first place, but for exceptional cases, his powers of expression and description are limited and he is unable to tell the Court what he really knows. In the second place, he is usually quite as strongly prejudiced in favor of his employer as the 'expert' witness, and is much less adroit in concealing that prejudice.

In the matter of partisanship on the part of expert witnesses, it may be said that it is partly due to loyalty to the employer and partly to a desire on the part of the witness to see his honest opinions regarding geological structure prevail. In this respect his partisanship is usually no more pronounced than that of the man who argues for his pet theory in any purely scientific discussion. Geology is not an exact science and there is always a chance for honest differences of opinion; and, while some one must be wrong, it is not always possible for a human being, be he judge or geologist, to determine which one.

Because there are usually two defensible sides to every mining case there are comparatively few cases in which an expert witness having accepted a retainer from one side declines to proceed after an investigation of the facts. But to say that there are none is entirely wrong, as every one knows who has had much practice of that kind. It is doubtless true that there is no "record" of such cases, for naturally no one wishes to have them recorded. The employer does not, for he thinks (and rightly too) that his case would be prejudiced in court if it became known that a competent man had refused after investigation to support him. The expert witness does not, because he does not wish to injure a man who has had sufficient confidence in his ability and integrity to engage his services. The suggestion that the Court employ competent men for independent investigation appears to be a good one and is somewhat along the lines of suggestions which I have made before. Sad to relate, however, in the only case where I have heard that this was done the judge is said to have finally decided exactly opposite to the findings of his own independent investigator. But there were other 'experts' for both sides in that case and he was probably too strongly swayed by the side which held views contrary to those of his 'expert'.

I have suggested that all litigation connected with extra-lateral right questions be submitted to tribunals consisting of one mining lawyer, one mining geologist, and one mining engineer; but I do not know that this would be a panacea for all extra-lateral right troubles. The real remedy, so far as the future is concerned, would seem to be the repeal of the "iniquitous law".

San Francisco, June 17.

ALBERT BURCH.

The Editor:

Sir—Mr. Burch possibly has misapprehended the point of view and the spirit of the article in question. An "amateur" must necessarily be a participant in a game, whereas the article merely discussed sundry aspects of mining litigation from the standpoint of a casual spectator, only superficially versed in the ways of the courts and the vagaries of 'justice'. In the first paragraph of his letter Mr. Burch infers that I would substitute "common sense" for "law and evidence"; on the contrary, I simply point out that Judge Bollinger has apparently used practical common sense instead of technical theory in interpreting the evidence and in construing the law. However, I feel gratified to have aroused the interest of one whom we all know to be among the foremost and most honorable of the 'professionals'.

San Francisco, June 18.

A. B. PARSONS.

Coloring of Glass

The Editor:

Sir—In your issue of June 11 Francis Drake comments on the discovery that white glass under certain conditions will turn purple. If Mr. Drake were to walk down any of the main streets of San Diego, a city blessed with an unusually large proportion of sunny days, he would find that a large number of the electric-light globes have a distinct amethyst tint, and some quite a deep tint. The chemical reactions that bring about this change in white glass are, I believe, no more understood than the reason why high-grade native peroxide of manganese is used in the manufacture of white glass to correct the color that otherwise would be imparted to the glass by the oxides of iron, almost invariably found in some proportion, in the silica used. Inasmuch as ferric salts almost always are of a deeper color than ferrous salts, one would have expected the addition of peroxide of manganese to have exactly the reverse effect to that which it has. The probabilities are, therefore, that the reaction is a physical rather than a chemical one, and that a color is produced by the peroxide that kills the color produced by the iron. Be that as it may, the prolonged action of sunlight brings about chemical change in the manganese salt that causes the amethyst color. This, of course, only clears the matter up to the extent that the amethyst color due to the prolonged action of the sun's rays on white glass is caused by manganese salts, originally introduced to make the glass white.

It is a long time since I had occasion to study glass manufacture, and it is possible that by now some better explanation may be forthcoming.

Victoria, B. C., June 14.

F. H. MASON.

THE lead produced in Alaska in 1919, according to the U. S. Geological Survey, is estimated at 687 tons, valued at \$72,822, compared with 564 tons, valued at \$80,088, in 1918. The output of lead in 1919 was derived from the concentrates of the mines at Juneau.

The Mining Industry of Mexico: A Historical Sketch

Part I

By Robert G. Cleland

THE COLONIAL PERIOD

"When a bonanza has been discovered, the fame of the discovery spreads through the whole kingdom, and the odor of its richness brings crowds from the most remote parts to the newly discovered districts. What was before a waste becomes on a sudden an inhabited neighborhood."—Gamboa, 'Commentaries on the Mining Ordinances of New Spain'.

INTRODUCTION. Mexican history is full of striking developments. The most significant of these was the remarkable rapidity with which the Spanish colonists over-ran the vast area known as New Spain and established settlements, and in many places flourishing cities, where only the wilderness or Indian villages had existed before. Behind this dramatic story of exploration, vigorous conquest, and permanent occupation lay many motives. Religious zeal, the haste to forestall any advance of rival nations, an age-long desire for Oriental trade, the eager search for those alluring creations of Spanish imagination—the island of the Amazons, Cibola, Quivira, the mysterious and fabled straits of Anian—these were all factors in the rapid subjugation of Mexico to Spanish rule.

But more far-reaching than any such influences were the discovery of precious metal, especially of silver, and the subsequent development of the mining industry. Indeed, with few exceptions, the history of Spanish advance, after the conquest of Mexico City by Cortez, is simply the story of the opening of fresh mining districts, one after another, and of great rushes to the new finds, which in point of magnitude were not greatly inferior to the Klondike and Goldfield stampedes of our own time. To trace each of these 16th and 17th century rushes (for, as already indicated, the mining rush in Mexico was nearly a century old before the voyage of the 'Mayflower') could require much more space than the limits of this article permit. It is enough to point out that the founding of Zacatecas, Pachuca, San Luis Potosi, Parral, Chihuahua, Nuevo Leon, Monterrey, and a score of other cities of importance in Mexico dates back to the discovery of some rich silver deposit and the establishment of a mining camp, which, almost over-night, grew to be a populous and permanent city. Indeed, from Mexico City to the Rio Grande, outside a few port towns on the Gulf or the Pacific, such as Tampico or Acapulco, one can scarcely find today a Mexican city of any size that was not established as a direct result of a mining boom.

The mines of New Spain not only served as a great stimulant to exploration and settlement; they also constituted the very centre of economic activity through-

out the colonies. Aside from the proprietors and laborers who obtained their living directly from the industry, nearly every other business in Mexico, as well as many in Spain itself, depended upon the prosperity of the mines for its existence. The Crown likewise derived the greater part of the revenue received from the colonies either from taxes levied directly upon the product of the mines, or from tariffs upon goods and materials used by the mining communities, or from the royal monopoly of the sale of mining necessities, such as gunpowder and quicksilver. The merchants were also dependent upon the mining centres for markets; and agriculture, especially in the interior, was carried on almost wholly as an adjunct to the industry. The hordes of laborers and animals employed at every large mine had to be supplied with food; and, in furnishing the corn, beans, *pulque*, and meat, as well as the horses, mules, and hides necessary for the business, Mexican agriculture found its chief incentive.

Social distinction also came from the mining business, especially as the King created a number of noble families from among the wealthier proprietors. The mines of Real del Monte made a poor store-keeper, Pedro Terreros, one of the richest men of his generation, and finally made him Count of Regla. The fortunes derived from the bonanzas of Guanajuato made famous José de Sardañeta, Francisco Mathias, who was created Marquis of San Clemente, and Antonio Obregon, the Count of Valenciana, whose fortune was not far from a hundred million dollars. The Bustamantes were ennobled, thanks to the wealth of Batopilas; and the Fagoagas came into prominence through the Pavillon bonanza at Sombrerete.

The church also derived great revenue from the mines. Sometimes this came from special levies, such as the one that was used to build the magnificent cathedral at Chihuahua; but more commonly it took the form of donations or bequests from generous individuals. Pedro Terreros, already spoken of, not only sent an expedition of sixty monks to the Apache Indians at his own expense, but gave \$20,000 monthly for two years and a half to the church of the College of San Fernando, and some \$70,000 for other religious purposes. The Bordas, Joseph and Francisco, having made an unbelievably large fortune after various ups and downs, donated more than a million dollars to build and furnish a church at Tasco, where one of their mines was situated.

MINING LAW. Mining played a significant part in every branch of colonial life, and contributed largely to

the royal treasury; it was, therefore, an object of great solicitude on the part of the Spanish Crown. An elaborate and in many respects admirable mining code governed the conduct of the industry and regulated its affairs to the most minute detail. This code, which in fact furnishes the basis of Mexican mining law today, consisted, in colonial times, of five parts, as follows:

1. The mining ordinances in effect in Spain prior to 1584;
2. The so-called Code of Philip II, promulgated in the colonies in 1584;
3. Royal decrees, of various dates, generally dealing with specific and sometimes purely local matters;
4. Regulation of individual colonies or provinces; and
5. The systematized and scholarly body of laws issued by Charles III in 1783 and known as the New Code.

Under the code of 1584, and in all laws thereafter, deposits of gold or silver, whether located on public or private ground, were declared the property of the Crown and thrown open to public denouncement. Anyone accordingly could prospect on public or private land "without any hindrance or interruption from the owners, or from any other person whomsoever", subject only to the obligation of paying for such damage as his prospecting or 'trial-pits' might cause. The process of denouncement was hedged about with certain technicalities, which need not detain us here; but it is interesting to note that, under colonial law, a concession to the claim was not issued until the denouncer had sunk a shaft three *estados*, or approximately 20 ft. in depth. If this were not done within three months, the concession was forfeited, and the claim was again thrown open to denouncement. An official inspection had to be made when the shaft was finished; and at the conclusion of this (in all probability a mere formality), the inspector stood at the mouth of the shaft and called three times for prior claimants to appear and prove their right to the property. If none came, the proceedings were closed by throwing a handful of grass or a few stones into the open pit.

The dimensions of the colonial *pertenencia*, or unit of mining concessions, varied under the different codes. The older laws made it rectangular in shape and of uniform size, covering a surface area of 50 by 100 *varas*.¹ Later, although the size of the ordinary claim remained the same, a discoverer's *pertenencia* was created, 60 by 120 *varas* in size. Under the law of Philip II, these last dimensions were given to the ordinary claim and the dimensions of the discoverer's *pertenencia* were increased to 80 by 160 *varas*. In all colonial laws, the *pertenencia* was considered indivisible; and, as its planes ran vertically, the boundaries of a claim were definitely fixed both above and below ground, in marked contrast to the uncertainty of boundary limits in the United States.

The law also contained specific regulations to prevent

the careless or reckless working of mines, and sought especially to minimize damage from flood or caving, by detailed provisions for timbering, supporting pillars, and unwatering. It is scarcely to be inferred, however, that these elaborate precautions were always zealously or intelligently enforced by the officials charged with the inspection of the mines.

Another interesting feature of colonial law, which has been abandoned and re-adopted with modifications more than once in later Mexican history, was the requirement that all claims should be worked or else become forfeited to the Crown. The Code of Philip II provided that four men, at least, must be kept employed on each *pertenencia*, and that failure to keep such persons at work for a period of four successive months destroyed all rights of ownership and again threw the property open to denouncement. Only war, pestilence, or famine, occurring within 20 leagues of the mine, could be offered as an excuse for failure to meet this requirement.

In all these laws, the purpose of the Spanish sovereign was to develop the mineral resources of Mexico through individual initiative and at the same time to protect the ore deposits from reckless or careless exploitation. Besides allowing the widest freedom for denouncement, various other privileges were held out to stimulate the industry. Proprietors were granted the use of forests and water to carry on their operations, and were permitted to expropriate either public or private land for mine plants or reduction works. In many other respects, too, the industry was placed on a more favored basis than were other colonial enterprises, but the lot of the Mexican mine-owner was not always a happy one, even with the royal favor behind him. Aside from the natural difficulties incident to his business, there were other obstacles of an equally formidable nature. One of these was the heavy burden imposed by taxes and other government exactions.

Royal Taxes and Monopolies. "Quicksilver is here very deere, for here is almost none to be had for any money to worke in the gold mynes; for without Quicksilver wee cannot refine out gold. And no man upon paine of death may bring any from Spaine hither; but all must come for the King's account; and so the King doeth sell it here; there is exceeding great gaine therein. And thus I rest: From Mexico, the 30 of May 1590".—Bartholomew Cano.

The Spanish government, as already indicated, sought in many ways to encourage the mining industry, an interest that arose primarily from a desire to increase the royal revenue by stimulating the output of precious metals and the sale of mining supplies. Taxes, both direct and indirect, were many and burdensome; and, too frequently, in its desperate need for funds, the Crown imposed such heavy levies that the mines fell into decay and the exports of silver greatly decreased.

The most important of the direct taxes was the royal fifth, or *quinto*, a 20% royalty levied upon gross output. The fifth was afterward reduced to a tenth; but in addition there were assay fees and coinage dues, which brought the total in direct taxes to something over 16% of the gross production. Under the law, gold and silver bullion could not be used in trade until coined at the

¹A vara is 33 inches. Under modern Mexican law, a *pertenencia* is 100 metres square, equivalent to a hectare, or 2.47 acres.

mint in Mexico City, but this regulation was impossible of enforcement, and in the northern districts, especially, unstamped silver (*plata pasta*) was the chief medium of exchange. The practice, however, was carried on at a serious loss to the miners, because goods given in exchange for bullion commanded double price, and a mare of silver, worth eight dollars at the mine, brought only four dollars and a half in Chihuahua or Sonora.

Indirect taxes, in the form of import duties and the royal monopoly on gunpowder and quicksilver, were a more serious handicap than the direct levies. At the close of the 18th century, Mexico required fully 1,300,000 lb. of gunpowder annually to keep her mines in opera-

to increase it in another. As the quicksilver mines of Spain (Almaden) looked to the colonies for a market, such pressure was brought to bear upon the king that the mining of quicksilver in Mexico was forbidden. However, while most of the quicksilver came from Spain or from Germany by way of Spain, Mexico also drew upon the mines of Peru, and to some extent derived her supply from China and the Philippine islands, by means of the Manila galleon. The price of the metal varied from time to time, depending upon the will of the individual sovereign. In 1590 it was fixed at 187 pesos per quintal, or 1.87 pesos per pound. By 1750 the price had been reduced to 82 pesos per quintal; in 1767 to 62

tion. The manufacture of this was under royal control, but many illicit factories existed and much powder was also smuggled in through Vera Cruz, so that the royal monopoly was far from complete. The price ranged from six to eight reales per pound, and even the lower figure represented a profit of 200%.

The royal monopoly on quicksilver was far more successful than that on gunpowder, and furnished one of the most troublesome questions in the history of colonial mining. Quicksilver was an absolute essential in the business, and its scarcity or abundance, its cheapness or dearness, largely determined the yearly output of the mines. In the conduct of the monopoly, accordingly, the king was frequently "between the devil and the deep sea". If he fixed the price of quicksilver so as to assure a large profit, he reduced the production of silver, and cut off the royal revenue in one direction while seeking

posos; and by 1778 to approximately 11 pesos. The annual consumption toward the close of the 18th century was over 1,500,000 pounds.

LACK OF CAPITAL. Another serious difficulty that retarded colonial mining was a lack of the capital necessary to finance the industry in a manner at all commensurate with its needs and opportunities. The joint-stock company, which played such a vital part in England's commercial and industrial expansion during the latter 16th, 17th, and 18th centuries was not known in Mexico. Partnerships were common enough, it is true, and the form of lease known as the *avío* to some degree met the needs of co-operation. Under Charles III also, a mining bank, supported by a percentage of the coinage dues, was established to finance mining ventures; but although this

Occasionally this decree was relaxed, but generally speaking, the prohibition stood.

proved beneficial for a number of years it came to an end with the outbreak of the French wars in Europe, when its funds were sequestered by the Spanish government and became lost forever to the mining business.

The commonest method of obtaining operating capital in colonial days was a sort of tripartite affair, in which mine-proprietor, ore buyer or *rescatador*, and wealthy merchant took part. The *rescatador*, securing an advance of funds from the merchant, supplied the miner with capital by buying the ore at the mine. He then reduced the ore and sold the silver to the merchant, in whose debt he stood, for a sum much below the market price. Under such an arrangement, operating mines could obtain funds to meet current needs, but the rates of interest were oppressive, and the supply of capital was too limited for large-scale operations.

Of course, where a mine was in bonanza the question of capital took care of itself. But the proprietor, when such good fortune was his, made little provision for the lean years of development necessary when the bonanza ended, or to meet unexpected disaster from flood or fire. Instead of the proceeds of the mine going back into the industry, they went too largely to gratify the lavish tastes of the proprietors or to build and adorn cathedrals, or for other unproductive purposes. As early as 1582, Henry Hawks, an English merchant who spent five years in Mexico, thus described the ostentatious life of those whom the mines were making rich:

"The pompe and liberalitie of the owners of the mines is marvellous to beholde; the apparell of both of them and of their wives is more to be compared to the apparell of noble persons than otherwise. If their wives go out of their houses, as unto the church, or any other place, they go out with great majesty, and with as many men and maids as though she were the wife of some noble man. I will assure you I have seen a miners wife goe to the church with an hundred men, and twenty gentlewomen and maids. . . They are princes in keeping of their houses, and bountifull in all maner of things."

Similarly, about the middle of the 18th century, Don Francisco Gamboa, greatest of all authorities on colonial mining, found that the miner's chief enemy was the miner himself, because, commonly speaking, he was "prodigal, unlimited in his indulgence in expense, luxuries, and vices"—all of which seriously hurt the industry by depriving it of the capital it so greatly needed.

COLONIAL LABOR. Other difficulties, such as lack of fuel, primitive transport facilities, banditry, and danger from Indian attacks, all retarded the industry. But probably the most serious problem of the proprietor was the labor question. The lack of machinery in Mexico made necessary the use of the other forms of power—man or mule. The difficulty of securing labor in early colonial times was partly overcome by the adoption of a form of slavery known as the *mita* system, by which the inhabitants of native villages could be transported forcibly to the mining districts and the Indians compelled to work the mines. Negroes and condemned captives were also used freely; but even under such conditions there was continual complaint of a shortage of labor. Conditions in the earlier years, from the laborer's standpoint, were terrible beyond description. Abuse, privation, ac-

cident, and disease carried off thousands of the poor wretches, whom the Spanish conquerors forced into an occupation that bore the reputation of being "attended with every pain which hell itself could inflict"; and, according to some authorities, with inflicting some forms of punishment of which hell itself had never heard.

The following quotation from a Spanish writer, while perhaps somewhat of an exaggeration, gives at least a vivid picture of these conditions:

"The Indians came from seventy leagues and upwards bringing provisions and whatever was needful. And when they had arrived, the Spanish mine-masters would detain them for several days to do some specific work. The provisions they had brought for themselves were soon exhausted; and then the poor wretches had to starve, for no one would give them food, and they had no money to buy it. The result was that some died on their way to the mines; some at the mines; some on their way back; some just after they reached home.

"The number of deaths was so great that the corpses bred pestilence, and for half a league around a certain mine and on the greater part of the road to it, one could scarcely make a step except upon dead bodies or the bones of men; and the birds of prey, coming to feed upon these corpses, darkened the sun."

But gradually the *mita* system died out, and slave labor, except here and there, gave place to a semi-free, semi-peonage system, under which negroes, Indians, and *mestizos* furnished the great bulk of the labor-supply and passed the occupation down from father to son. Conditions, however, were still far from satisfactory. There were plenty of laws, it is true, to protect the laborer from unnecessary danger (for instance, there was an ordinance of Charles III, requiring the installation of proper steps and ladders, and the keeping of these in sound repair), but the enforcement of such laws was seldom taken seriously, unless the safety of the mine itself was involved; and even then, inspectors were not always either conscientious or competent, so that disaster and accidents were of appalling frequency, even at the close of the colonial era.

The labor itself, even barring accident, was still oppressive and ruinous to health. The *tenateros*, or packers, who carried ore and water in rawhide bags suspended on their backs by straps across the forehead, according to Humboldt, "remained continuously loaded with a weight of from 225 to 250 pounds, and constantly exposed to a very high temperature, ascending eight or ten times successively, without intermission, stairs of 1800 steps". Severe as this labor might be, however, it was not so unhealthful as that of the *barcnadores*, or powder-men, whose span of life seldom exceeded 35 years if they continued their occupation beyond a certain period.

Above-ground, conditions were equally conducive to disease. The dust and glare of the patios brought blindness to many of the women and children who broke up the ore for amalgamation. And a large part of those engaged in carrying on the actual process of amalgamation spent their lives "in walking barefooted over heaps of brayed metal, moistened and mixed with muriate of soda, sulphate of iron, and oxide of mercury". Humboldt records that persons so engaged seemed to enjoy perfect health, but one may well question the accuracy

of his statement. In smelting operations, at any rate, the testimony lies all the other way. Here the laborer was compelled to breathe the poisonous fume and vapor that arose for nearly an hour after water had been poured on the hot slag. The men drank unlimited quantities of water, became bloated, suffered acutely from fluxes and stomach cramps, and lost the use of hands and feet.

In the matter of wages, however, the mine employee fared better than any other laborer in Mexico. At the close of the colonial period, he received from five dollars to five dollars and a half, per week of six days, whereas ordinary labor on the haciendas was paid about a dollar and a half. These high wages, however, were somewhat

Humboldt's record of thirty thousand underground laborers, and five or six thousand engaged in various capacities above ground, appears to me to be below the mark. But no other figures can be offered as a substitute.

In many respects, the miner of colonial days was much the same as his descendant of today. From most of the literature of the time, he appears to have been a superstitious, thieving, gambling, licentious, drunken, careless, improvident, and lazy rascal, with a few remarkable and counter-balancing virtues. He would sometimes buy rich cloth or fine cambric to gratify his love of display, only to use the holiday material next day for wadding or as a pad to protect his hands. Saints' days and church

MEXICAN MINERS AT WORK

offset by the common practice of paying in goods instead of money. Prices were exorbitant, and not infrequently the laborer was compelled to accept articles for which he had no use. So serious had become the abuses under this system that the Code of Charles III (1783) made the practice illegal, and forbade the payment of wages in "merchandise, effects, fruits, or provisions". The same ordinance required the proprietor to pay his men each week in ore, coin, or bullion and imposed a severe fine if any reduction were made in the rate of wages "established by long usage and adopted in all the mining districts". Accounts were kept by the *rayador*, or paymaster, who was required to see that each man had a sort of tally-sheet upon which the amount of his wages was indicated by circles, lines, and half-lines, to represent the dollar and its various fractions.

Of the actual number of persons employed in the industry during colonial days, there is no accurate record.³

festivals were continually calling him off to celebrate. Whenever possible, he got riotously drunk, especially as the ore-buyers to whom he sold his share of the mine's product (*pepena*), and whatever he had been able to steal during the week, often paid him in liquids instead of coin. The *vingarro* and *chingirita*, which formed the chief medium of exchange in these transactions, had a kick that the consumer of the strongest of modern jackass brandy might well admire, and led to frequent violence and bloodshed, and an endless amount of lost time.

Even more annoying, from the operator's standpoint, was the ingrained habit of theft among the employees. This trait, which the mine superintendent in Mexico has always to deal with, has its roots in a long forgotten past.

³At Guanajuato, 5000 men were employed above and below ground; while the single mine of Valenciana carried 3100 laborers on its payroll in 1803.

Two hundred years ago, the miners were searched as they left the mines, even as they are to this day in many parts of Mexico, and rather a disgusting process it must have been, from contemporary accounts of the proceedings. The best characterization I have yet seen of the Mexican miner in this respect was given by Gamboa in 1761. In speaking of the mine laborers, he wrote:

"They steal the iron picks and crow's; they steal the candles; they steal the ore, by means of very subtle and dexterous contrivances and stratagems; they steal the silver from the smelting works and from the vats and washing places in the amalgamation works, with no less dexterity, under the very eyes of the overseers. Upon one occasion, in the mining district of El Monte, the amalgamator being present, and the workmen shut in, several ingots of silver disappeared from the room, and on the circumstances being investigated, it was found that they had fastened a string to the ingots, which being carried out by the gutter through the force of water, the party posted outside for the purpose was enabled to drag away the silver. They steal clothes and money from each other, and if they continue to elude the searcher at the mouth of the mine, they will afterwards boast in his presence of the thefts they have committed. They steal the rich ore by throwing it among the rubbish. In a word they conjugate the verb 'rapar' in all its moods."

Evidently Gamboa, who was a man of practical experience in the business of which he wrote, spoke from a full heart. He naively added, after this description, that,

"Miners of discreet and Christian spirit generally proclaim a pardon for all thefts every Lent"—because, as they knew there was no chance of recovering the stolen ore, the pardon cost them nothing, and if "every transgression were visited with severe chastisement, the mines would soon be abandoned by the workmen."

METHODS. As already mentioned, Mexican miners made but scant use of machinery. Ore was generally carried in rawhide sacks on the backs of the *tenateros*, three of whom, it was estimated, were commonly required, in large mines, for each powder-man employed. These packers ascended from the lowest levels of the mine by crude steps cut in the rocky wall, or more commonly by means of chicken ladders or poles, notched deep enough to allow a precarious hold for their bare feet. When water became a serious problem, as it did in most mines, an adit (*socabon*) was driven into the hillside to drain the workings. Some of these showed great engineering skill. At Taseo, where silver was first discovered, there was said to be one over a third of a mile long, in which a man might ride a considerable distance on horseback. In the mines of Rayas, at Guanajuato, there was one of similar dimensions; the great adit that unwatered the famous Viscaina lode, was 7 ft. wide by 8½ ft. high and over a mile long. It required more than 12 years for its construction.

Where an adit was not feasible, the mines were unwatered by *tenateros* with their rawhide bags, or by the crude horse-whims, known as *malacates*. These were also used to bring ore to the surface, and served both purposes reasonably well where conditions were favorable. In most instances, however, they were both inadequate and costly. The rawhide bags, constantly rubbing against the rough walls of the shaft, wore out rapidly; and as they cost from one to two dollars each, the continuous replacement of them constituted a considerable item of expense. One such bag full of water would weigh more than half a ton; consequently, a great number of

horses or mules were required to operate the whims in every large mine. The Ramon pit on the Viscaina lode, for example, in 1783 employed 28 whims, each of which required 40 horses to keep the lower workings free from water. The cost of the operations exceeded \$10,000 per week.

The use of so many whims made it necessary, of course, to sink very much larger shafts than would otherwise have been required, thus entailing a heavy expense, which could have been avoided by the use of less cumbersome machinery. The *tiro general*, or main shaft, of the Valenciana was a striking illustration of this point. Octagonal in shape, its walls lined with masonry for a hundred feet from the surface, and with a diameter of 33 ft., this huge shaft represented the acme of Mexican skill. Twelve years were required to sink it to a depth of 600 ft.; the estimated cost of the entire undertaking was more than a million piastres. When completed, it had a depth of 1730 feet.

In some respects, the colonial operations were carried on with remarkable skill. The common miner was an expert judge of ore and had an abnormal faculty for estimating its value. He was also a great prospector, so that few new districts of any magnitude have been opened in Mexico since colonial days. On the whole, however, the industry suffered severely not only from an insufficiency of capital but also from crude and wasteful methods, and from a lack of technical skill. Humboldt, for example, estimated that two-thirds of the powder used in the mines was wasted; Gamboa, a trained engineer himself, spoke of the mine surveyors and chief *alcaldes*, who had oversight of mining operations, as "strangers to the profession and ignorant of its rules". The ordinance of 1783 sought to remedy this lack of technical training by establishing a School of Mines, in which young men might receive a scientific course, to be followed by three years of practical experience before graduation. Unfortunately, the success of this experiment was destroyed by the revolution.

The metallurgical processes were many and various, but in the case of silver only two are worthy of mention. These were smelting and amalgamation. The great wealth of the Mexican mines lay not so much in exceptionally high-grade properties as in the almost unlimited quantity of medium-grade ore produced.⁴ The extraction of this was made possible by the famous patio process, discovered in 1555 by Bartholomew Medina, a mining engineer at Pachuca. To this process, by which at least 75% of the colonial output was obtained, Mexico owed her phenomenal mineral development. Its characteristic features are too well known to my readers to require repetition.⁵ Certainly, it was the most distine-

⁴According to Humboldt, the average silver content of Mexican ore was three or four ounces per quintal, or between sixty and eighty ounces per ton. At Guanajuato, where the patio process reached its highest development, ore yielding about three-quarters of an ounce per quintal was profitably treated.

⁵See T. A. Rickard, 'Journeys of Observation', pp. 129-147, for a full description.

tive feature of Mexican mining, not only during colonial days, but during most of the 19th century as well. In the great silver districts, the *haciendas de beneficio*, with their high white walls, built as a protection against robbery and theft, their courtyards covered with *montons* or *tortas* of metal in various stages of amalgamation, the innumerable laborers breaking ore for the *arrastres* or grinding-mills, and the half-naked men and boys, or droves of animals, treading the huge slime-pits, struck a chance visitor as nothing else connected with the industry.

Salt, magistral, lime, and quicksilver constituted the chief essentials in the patio process. The quicksilver has already been spoken of as a royal monopoly. Salt was also an item of very serious expense and could be pro-

duced in relatively few places. Between San Luis Potosi and Zacatecas, there was a famous salt lake—the Laguna del Penon Blanco—which dried up during several months of each year, allowing the salt to be scraped from its bed. The salines of Vera Cruz, Tampico, and Colima also furnished the article in an impure form; the product of various salt springs was similarly utilized. The cost of the salt varied largely with the distance required for its transportation, but even in the place of production it was worth half a piastre per bushel.

of waste eight times higher than that incurred in European mines during the same period. The amount of magistral used in the process varied with the character of the ore, but seldom exceeded five times the weight of the mercury.

Ores that could not be treated by the patio method were calcined or smelted, and then refined. In this process, the Mexican used a variety of methods and furnaces. One of the commonest of the primitive smelters was the *horno* or adobe furnace, which differed somewhat in type from place to place. That in common use in the Santa Eulalia district was about 18 in. wide at the top, 16 in. across the bottom, and stood nearly 4 ft. high. The blast was supplied by bellows at the back, which might be worked by hand or mule, depending on the size of the

A STREET SCENE IN CHIHUAHUA

The copper pyrite used in the preparation of magistral sometimes costs as high as ten dollars per carga. Quicksilver was used in varying quantities, depending upon the amount of silver contained in the mixture. Generally, the proportions adopted were six parts of quicksilver to one of silver. About as much quicksilver was lost in each amalgamation as there was silver recovered, a percentage

furnace. The furnace just described held a charge of something more than 100 lb. The chief cost of operation in this method lay in the difficulty of securing charcoal, especially where wood was scarce, and the proper fluxes to be used with the ore.

For extraction of free gold, the machinery in commonest use was an *arrastre*. This was a crude drag-mill built usually near a stream of water and turning in a rock and clay or log-wall pit, some 12 ft. in diameter and 3 ft. deep. The bottom of this pit was lined with flat stones and wherever cracks occurred, these were filled with clay. The grinding apparatus consisted of two flat-bottomed stones, weighing five or eight hundred pounds each, attached by rawhide or grass ropes to the lower cross-piece of an upright wooden shaft, set in the centre of the floor. Another bar higher up made a sweep-like arrangement, to which horses or mules were hitched. As these were

driven around, the stones were dragged across the floor and the ore, broken to walnut size before being put into the mill, was ground to powder. A small stream of water flowing into the mill kept it filled to a depth of five or eight inches, the pulp being carried off by the overflow. The gold, sinking to the bottom, combined with quicksilver. About half a pound of this was required per ton of ore, and under favorable conditions as much as 50% of the gold was caught.

PRODUCTION. The figures of production during the colonial period, for reasons which cannot be explained here, are much more likely to be legendary than exact. The yield of certain great bonanzas, however, is fairly well authenticated and may prove of interest. The Cañada, one of the famous properties in the Real de Tlapujubua, yielded close to 2,000,000 oz. of silver annually when in bonanza. La Esperanza, on the Veta Grande of Zacatecas, produced nearly 4,000,000 per annum. The mine of La Purissima yielded a net profit of over \$200,000 annually for nearly two decades, and in 1796 produced six times that amount. Another mine in the Catoree district had a yearly output of nearly \$2,000,000. The mines of Sombrerete gave a net profit of \$4,500,000 in a few months of bonanza. Quebradilla produced more than \$200,000 in a single week; the mines of Pachuca, Bolanos, and Batopilas, to mention only a few at random, were all producers of the first rank. But the mines on the Viscainia lode at Real del Monte, and the great Valenciana, probably surpassed anything else in Mexico. The Viscainia was mined from the 16th to the early part of the 17th century. The workings then became flooded and were not re-opened for half a century. About 1740, however, a miner named Bustamente conceived the idea of running an adit to cut the vein at a lower depth. He died before the enterprise could be completed, but his partner, Pedro Terreros, finished the undertaking in 1762. Before 1774, he had made a net profit of over \$5,000,000, and was recognized as one of the wealthiest men in the world. Thirty years later, the mine was still producing close to 500,000 oz. per annum. The Valenciana first came into bonanza in 1768. Within three years, it was producing about \$3,000,000 per annum, and for more than a generation continued this phenomenal yield.

The total production of silver in Mexico, from 1690 to 1803, was estimated by Humboldt at slightly over 1,200,000,000 ounces; the gold and silver together, produced and coined during the same period, had a value of about \$1,500,000,000. The output of the two metals for the whole of the colonial period (1525-1810) Humboldt fixes at approximately \$2,000,000,000. The average annual yield during the reign of Charles III, when the industry was at its height, was close to \$22,000,000, or nearly 20,000,000 oz. of silver and some 60,000 oz. of gold. Considering the purchasing power of money in that day, the Spaniards' lack of machinery and technical skill, and the generations of exploitation already accomplished before the dawn of the 19th century, one can readily understand the significance of Humboldt's apt and often

quoted phrase—"Mexico, the treasure-chest of the world".

(To be Continued)

ALUMINUM is almost the only metal available for the manufacture of light alloys, according to W. Rosenhain, whose lecture before the Royal Society of Arts appears in a recent issue of the 'Journal' of the Society of Chemical Industry. Of other possible metals, alloys consisting mainly of magnesium are disappointing; beryllium is not yet available. After describing briefly the process for the production of aluminum by electrolysis of pure alumina dissolved in molten cryolite, it was pointed out that there is no satisfactory method for refining aluminum, and that its purity is dependent on that of the materials used in its manufacture—notably the alumina and the carbon electrodes. Consumption of the latter is approximately equal, weight for weight, to the metal produced, and special petroleum coke having a low ash is essential for their manufacture. The necessity for cheapening the cost of aluminum was emphasized. In this connection mention was made of the new nitride process whereby bauxite, carbon, and nitrogen are made to react at a high temperature with formation of aluminum nitride, which on treatment with soda yields sodium aluminate, with ammonia as a valuable by-product. The cost of preparation of pure alumina by this process is said to be very much less than by the present method. In dealing with the properties of aluminum, it was pointed out that its weakness lay in its mechanical properties, and therefore, for structural purposes where strength is required, alloying with other metals is necessary. The alloys of aluminum present the difficulty that, with the exception of zinc, and possibly magnesium, the range of solubility in the solid state for other metals—such as copper, nickel, manganese, iron, and tin—is low, and the addition of comparatively small percentages of these metals leads to the formation of hard compounds as free constituents, causing rapid decrease in ductility.

SOME years ago it was discovered that many of the laterite deposits of India were highly aluminous, and consisted of bauxite, states an Imperial Mineral Resources Bureau bulletin. Systematic field work by the Geological Survey has proved the existence of extensive deposits of bauxite in many parts of India, and chemical investigations have shown that certain of the Indian bauxites compare favorably with some of the best bauxites of commerce. The richest areas yet discovered in India are the Baihir plateau in the Balaghat district, and the vicinity of Katni in the Jubbulpore district, both in the Central Provinces. Bauxite of good quality has also been found on the laterite plateaux in the western parts of Chota Nagpur and in Sarguja, Bihar, and Orissa; in Bhopal and Rewah States, Central India; in the Satara district, Bombay, and in various parts of the Madras Presidency. The deposits to which most attention has been paid up to the present time are those of Balaghat and Jubbulpore.

An Address to Mining Students

On the Occasion of the Commencement of the Colorado School of Mines at Golden on June 10, 1921

By Frederick Laist

It was with a most profound sense of responsibility and many misgivings that I accepted the invitation extended to me to address you on this, the occasion of your Commencement, and if what I am going to say may prove to be of the slightest help to any one of you in shaping your course on the uncertain and oftentimes stormy sea of professional life, I shall feel that my presence here has not been utterly futile.

I have no desire to stand before you in the capacity of adviser, nor do I feel qualified to do so if I so desired. Young men have often come to me asking advice as to some immediate step they contemplated, and even under such comparatively easy circumstances I have found it difficult to say, "You should do this, or so". How infinitely harder, therefore, would it be to advise an assemblage such as you young men with all your diversity of tastes, ambitions, and abilities. Nevertheless those of us who have been through the mill have seen changes and brought away certain impressions and experiences which it may be useful to pass on to you. Outstanding among the changes of recent years is the passing, to a large extent at least, of the individual engineer—the free lance, as it were—and his gradual replacement by, or absorption in, that greater unit known as 'the organization'.

Through my talk today I hope to leave with you a picture of what it means to develop a great mining enterprise nowadays and of the human machine or organization upon which the successful outcome of the project depends. Perhaps this will aid you to make selection of your course with better chance of arriving at your desired goal.

You are at the commencement of your professional career. You have finished a course of study which is admirably adapted to serve as a foundation or groundwork upon which to build. So far you have done well, and I assure you that you will never regret the time you spent at school. Your four years here have placed you in a similar position with respect to your chosen profession as four years at West Point or Annapolis place the man who selects an army or navy career. You are the commissioned officers, as it were, of the great organization upon which humanity depends for its supplies of metals. In other words, you are presumed to have the basic knowledge which will enable you to become good leaders after you have acquired a practical knowledge of men and affairs.

When you were in high-school and were making up

your mind as to what kind of career to follow, whether business or professional, and if the latter, what profession, you knew that whatever choice you made would determine the course of your lives for years to come and so now again you must make a choice between the various branches of your profession, and the choice once again made, you must carry on, or stand to lose what may well be years of effort.

To begin with, the profession of mining as it is commonly called, may be divided into two main branches: mining and metallurgy. Mining has to do with the mining of ore. Metallurgy has to do with the treatment of ore. Mining and metallurgy go hand in hand and yet they appeal so differently and require so much knowledge of a special character that in most schools the student is permitted to specialize in one or the other during at least a part of his course.

The mining engineer, aided by his knowledge of geology, concerns himself with the finding of ore, and with the mining of it to the best advantage. The metallurgical engineer receives the ore, and with the aid of his knowledge of physics and chemistry, as exemplified in the various ore-treatment processes, separates the valuable metals from the gangue and from each other.

In the early days of mining, only the richest ores were made use of, and only the simplest methods, both of mining and metallurgy, were known and applied. A comparatively modest capital was sufficient to start a mining enterprise. Those days are past, generally speaking, and now enormous capital is needed for the beneficiation of the comparatively low-grade and complex ores from which our present supplies of metals are derived.

We hear much nowadays about the exploitation of the natural resources of the country—of the people being robbed of their birthright, and so on. This agitation is even extended to include water-power sites, as though water, once over the fall, could ever again be of use to the Nation. Modern mining and metallurgy are so largely dependent upon cheap power that agitation of this sort becomes properly of concern to the mining engineer, quite apart from the self-evident fact that the disuse of water-power constitutes a very serious economic waste, and every engineer as a good citizen should set his face against waste of every kind. Every horse-power we allow to run down our streams means hastened depletion of our limited supplies of oil and of coal, not to speak of the waste of human energy indirectly involved.

It goes without saying that the rights of the people—all of us—must be protected, and it is highly important for our representatives to enact legislation designed to prevent waste of our resources and to protect us from extortion and profiteering. At the same time, it is wrong to hedge around the resources of this country with red-tape so as to repel the capital which must be forthcoming before any benefits can accrue.

Very few people realize how relatively valueless is raw material, in the ground, and what an enormous expenditure of money, effort, and time is required to make it useful to mankind. For example, let us review the development of the so-called 'porphyry coppers', whose growth during the past fifteen years has been one of the marvels of modern mining and metallurgy. As is well known, these properties, practically without exception, were known to mining men and geologists for many years but were considered too low-grade and therefore valueless. In other words, they were not 'ore'. Abortive attempts had been made to work a number of them, but in vain. The Utah Copper Co.'s property was offered for sale in the late '90s for \$250,000, and was refused.

About 1900 experimental work had demonstrated to the satisfaction of some of the more far-sighted and venturesome mining engineers that these low-grade disseminated ores might be profitably worked, provided that the operation were carried out on a tremendous scale. The flotation process was unknown in those days, except for the old Elmore oil process, which had attracted some attention but was not taken very seriously. The copper-leaching process was also unknown, or at any rate undeveloped. Water-concentration, therefore, was the only process that offered prospects of commercial success and at best it could only be counted on to recover a comparatively low percentage of the copper minerals. This meant a very small yield from an already low-grade ore in the form of concentrate that would suffer further loss in smelting.

Agreement as to the successful outcome of the first porphyry undertakings was by no means general, and I know of a number of able mining and metallurgical engineers who were exceedingly doubtful as to the possibility of building up a successful business on the basis of such low-grade and difficultly treatable ores; and it required a good deal of courage to undertake the investment of the many millions of dollars needed to determine definitely the value of the deposits and bring them to the producing stage. It was possible to go slow up to a certain point, after which it was necessary to take what was little short of a leap in the dark. However, to the everlasting credit of the American engineer and financier, the leap was taken and successfully spanned the gap, with the result that tremendous reserves have been added to our copper resources, and hitherto worthless rock became valuable ore.

Probably many of you remember, not long ago, in what universal disrepute the oxidized silicious ores of copper were held. Even by the engineers who were developing the first porphyry coppers, the cap of oxidized ore, often referred to, rather contemptuously, as "copper-stained

rock", was of necessity excluded from the estimates of ore-reserves, as being of no value. In South America enormous masses of this character of ore were known to occur in the Atacama desert of Chile without attracting the favorable attention of mining engineers, although their copper content equaled and even surpassed that of the porphyries that were being worked with such marvelous success in North America. Finally, their development was undertaken, again by American capital and American engineers. After painstaking experimentation, a process of treatment was devised and then again it became necessary to expend untold millions in an unknown country on a new and relatively untried process. Such is the story of Chuquibambilla, and the same is true of the great property of the Anaconda company at Potrerillos.

When the engineers of the Anaconda company came to Potrerillos they found nothing but a few shafts, tunnels, and drill-holes in the heart of the Andes mountains at an elevation of 10,000 ft. Sixty miles from the nearest railroad, and that a railroad only by courtesy, as we understand the word in this country. Thirty miles from water. Thousands of miles from a base of supplies.

The first thing that had to be done was to prove the existence of a sufficient mass of ore. Although the ore-body had been roughly outlined, and, reasoning by analogy, the drill-holes and other workings indicated the presence of an enormous amount of ore, the correctness of this reasoning had to be more definitely established and more accurate information had to be obtained as to grade, character, and composition of the ore before going further.

This work took considerably over a year and had to be done under adverse conditions; all supplies had to be brought thousands of miles by water, unloaded at the port by lighters, hauled over a very poor railroad to a station called Pueblo Huidido, 40 miles in the interior, then hauled from there by means of mule-carts a distance of 56 miles over miserable roads, arriving finally at Potrerillos, 10,000 ft. above sea-level. The country being a desert, it was necessary to haul water for every conceivable purpose, and this water was so poor in quality that wherever it had to be used for generation of steam it caused a great deal of trouble in the boilers.

This preliminary work having been completed, operations could be commenced on the development and equipment proper. Remember that there was absolutely nothing to start with. The problem was entirely different from that of establishing a plant or factory in or near one of our cities. The first thing to be done obviously was to construct port works so that unloading of ships would be attended with less loss and could be done more expeditiously. A site called Barquito was selected, and a pier, warehouses, oil-tanks, and a small temporary power-plant were planned and built.

At the same time, work was commenced on a railroad to connect the mine with the existing Chilean railroad. The new railroad was in itself quite an engineering feat, in that it had to ascend from an elevation of about 2000

ft. to an elevation of 10,000 ft. in a distance of about 56 miles, and at the same time it was felt that in order to make it reasonably economical from the operating standpoint, a grade of 3% ought not to be exceeded at any point. It is quite impossible to convey to anyone familiar only with American mountain scenery, any idea of what it means to build such a road in the Chilean Andes, and I will not attempt to do so here. Suffice to say that at one point it was necessary to get from one side to the other of a canyon 2000 ft. deep, with mountain slopes on either side so steep that it was difficult in places to obtain a foothold for the roadbed.

In order to lighten the loads to be hauled to the mine as much as possible, it was decided to generate whatever power was needed, both in preliminary work, and later for operations, at the sea-coast. This necessitated the construction of a power-line almost 100 miles long.

A site for reduction works was selected about six miles from the mine and at an elevation about 1000 ft. lower. In order to tap the orebody and convey the ore to the crushing-plant, a railroad, running chiefly underground, had to be constructed and electrified. The tunnels on this road aggregate approximately three miles in length, and the last tunnel ends under the main orebody at a depth of 1000 ft. beneath the surface.

While all this was going on, surveys were made and plans were perfected for bringing in an adequate supply of water for milling and leaching operations. This water has to be brought from the Ola river, a distance of over 30 miles, over rough desert country, to the brink of the Pasto Cerrado, across which it will have to be brought in a siphon capable of withstanding a pressure of about 900 lb. per square inch, finally ending at the millsite, three or four miles farther on.

All of this work had to be guided and directed from administration offices established at Potrerillos, and in order to accommodate the staff and the workmen it was necessary to build a town. Houses had to be provided for people of the most diverse tastes and ways of living. A commissary had to be established where everything needed, not only to sustain life but to provide the comforts of life, could be purchased. Hospital, medical, and surgical attendance, police protection, amusements, churches, even a cemetery, had to be established. Obviously it was desirable to maintain good relations with the Chilean government and keep on good terms with the various officials, and this, oftentimes, is not as easy as it might seem, owing to differences in customs and ideals.

While all this was going on, a method of mining and a method of ore-treatment had to be decided upon. The two necessarily go hand in hand, and the mining engineer and the metallurgical engineer must each view his own problem to some extent from the standpoint of the other. This is particularly true when the orebody to be treated is a complex one and contains masses of both oxides and sulphides, as well as mixed ores.

Having settled on the system of mining to be used and the plan of treatment, the necessary stripping must be done, underground bins, cross-cuts, and raises must

be excavated, and carefully detailed plans of the reduction works must be made.

The planning of a plant of this kind is in itself a matter of many months and must be followed by the erection of thousands of tons of concrete, brick and steel under anything but favorable circumstances. Plans have to be made with extra care and attention to detail, owing to the great distance from the base of supplies. As in other porphyry mines, the quantity of ore treated daily will be very large. The plant will be, necessarily, a huge affair and will contain many different departments.

Some of the individual operations involved in the treatment of oxidized or mixed ores require such a degree of technical skill that only a few years ago mining men hesitated to apply them even in the mining districts of this country. For example, the manufacturers of sulphuric acid. Other departments are as follows: coarse- and fine-crushing plants, leaching-plant, precipitation-plant, sulphur-dioxide plant, concentrator, smelter, together with such auxiliary departments as power-plant, sub-stations, boiler-plants, foundry, machine, carpenter, and blacksmith shops, and even a brickyard, for the haulage of brick to a point so remote as Potrerillos would be very costly.

Now it must be apparent to you from this outline that the man in charge of a modern mining and metallurgical enterprise must have not only a good technical knowledge but must also be a capable administrator and executive, and the men whom he employs on his staff must have the qualities of loyalty and trustworthiness in somewhat more than ordinary measure. It is obvious that the efforts of the individual can accomplish little in an enterprise of this magnitude. Team-work is the only thing that can win, and this implies on the one hand a chief who has the respect and co-operation of his staff, and on the other hand an organization that will not only carry out orders but is alert and interested and is in itself harmonious in so far as relations between its individual members are concerned.

You have doubtless heard the terms 'centralization' and 'decentralization', and know in a general way what they mean. As a matter of fact, in every successful organization the centralization of authority on the one hand and its distribution among subordinates on the other, or decentralization, must be carefully studied and worked out.

At the head of the local organization stands the general manager, who in turn is responsible to the president and vice-president, whose headquarters are usually elsewhere. Under the general manager come such officers as mine superintendent, reduction-works superintendent, mechanical superintendent, railroad superintendent, chief accountant, purchasing agent, legal and medical advisers. Each of these men in turn has a staff, depending in number on the size and complexity of his department. For example, the mine superintendent will probably have several superintendents under him, each in charge of an individual mine or region. The reduction-works superintendent will have in his department

several superintendents, such as concentrator superintendent, leaching-plant superintendent, superintendent of acid plants, and so on.

This staff is generally built up of technically trained men, that is, men who have had a course such as yours. Under them come foremen, shift-bosses, machine-operators, and others, all without special training. The young engineers generally start in the engineering or laboratory departments under the immediate supervision of the chief draftsman, chief surveyor, or chief chemist. They are generally promoted according to fairly well recognized principles, taking into consideration ability, dependableness, and length of service.

In addition to departments of the kinds just enumerated, which concern themselves wholly with problems directly connected with operation, the larger companies are devoting more and more attention to building up and maintaining research laboratories, which have nothing to do with operation or production, but whose functions are of a more purely scientific nature. The research department attracts to itself engineers of a scientific rather than an administrative turn of mind and offers a career in pure science with unlimited possibilities. The research department of the New Jersey Zinc Co. and of the General Electric Co. each employs more than 200 men. You can see from this what an important factor organized research has become in modern industry. In these departments are to be found men of the highest and most diverse scientific attainments. Here we find mathematicians, physicists, chemists, geologists, and specialists of all kinds.

The rate of progress that can be attained by organized research is surprising when compared with the accomplishments of the individualistic methods of the past. As an example I might cite the development of the electrolytic zinc process in the research laboratories at Anaconda. The development of this process did not require the discovery of new scientific principles, but rather the combination of old and well-known principles of chemistry and physics with modern engineering. It had been known for many years that a solution of zinc sulphate could be electrolyzed with deposition of zinc at the cathode and formation of sulphuric acid at the anode, but it is a far cry from making a few grammes of electrolytic zinc in the laboratory without regard to cost by skilled chemists and producing regularly millions of pounds of metal under commercial conditions, implying low cost and the use of relatively unskilled workmen. This was the task of the research department, aided, as the work progresses and assumes larger proportions, by the operating staff.

The electrolytic-zinc process was developed in order to permit of mining certain complex ores that occur in considerable quantity in Butte. These ores contain zinc, lead, copper, silver, and gold. The metals are so distributed, however, that a treatment method which ignored any of them could not be profitable. The lead-smelter could not treat them advantageously owing to the fact that the zinc not only was not recovered but was

a serious detriment. The copper-smelter made no recovery of either zinc or lead; and the copper, silver, and gold were in themselves not of sufficient value to pay the expenses of mining and smelting. Selective concentration gave indifferent results, because the minerals contained in the ores were not separable by mechanical means. It was evident, therefore, that an entirely new mode of attack would have to be devised if they were to be made useful.

In work of this kind it is always wise to build on the experience of the past in so far as this is possible. A thorough search of patent and technical literature was therefore made before any laboratory work was started. This search revealed many proposals and tentative processes. Some of these could be eliminated as unpracticable or unsuited to local conditions, but some of them seemed worthy of laboratory investigation. Such investigations were made on three processes before definitely deciding on the electrolysis of zinc-sulphate solutions. All of this preliminary work took the time of probably a dozen men two or three months.

We were now ready for the next step, which consisted of operating the process in the laboratory on a small scale under conditions as nearly as possible identical with those that later would be encountered on a large scale. In this work the cells were operated day and night and the solutions were used over and over again exactly as would have to be done in the large plant. The same acid strength and methods of purification were used and the effect of various impurities on the electrolysis were carefully noted. Exact measurements, with calibrated instruments, were made of the amount of current needed to deposit a pound of zinc, of the roasting temperatures that gave the best results, and in short all the data that could possibly be obtained from a small-scale operation were secured.

It is important to note that this work was done with the process operating in a continuous manner and as nearly as possible duplicating large-scale conditions. You often hear it said that such and such a process worked alright in the laboratory but failed on the large scale. This is due generally to laboratory work that has been planned and executed improperly. The tendency of inventors, and, in fact, most people, is to allow the wish to be the father of the thought and to do their laboratory work under conditions that could not possibly be met in practice, salving their consciences meantime with the utterly false notion that on the large scale they can accomplish what they could not do in the laboratory. This is like the prospector who invariably expects to have his vein widen and grow richer with depth, whereas oftentimes a little unbiased reflection would convince him that the reverse was much more likely to be true. Our Western mining districts are strewn with monuments to man's tendency to self-deception.

Having operated our toy plant for several months without serious difficulties, that is, difficulties that could not be overcome, because difficulties continually kept cropping out, we were ready for the next step. This was

to construct and operate a small plant containing single units of machines, as nearly as possible of standard size. The experimental or pilot plant had a capacity of 10 tons of zinc per day. It contained a full-sized roasting-furnace, leaching, settling, and filtering equipment of standard design modified to meet the peculiar conditions of zinc-leaching, full-sized electrolytic cells, and a small reverberatory furnace for melting cathodes. Various kinds of metals were used in the construction of this plant in order to study the effect of the solutions on them under working conditions and thus determine the structural materials for the large plant. This is very important, as many a plant has failed or required costly alterations owing to the selection of faulty structural materials. Many a so-called acid-proof metal or material has proved to be a snare and a delusion.

In this plant the laboratory data as to roasting-temperatures, acid-strengths, current-efficiency, and so on, were verified or modified, and much additional information was collected that could not be obtained from a laboratory operation.

The value of an experimental plant as the predecessor of a large operation may be illustrated by an incident that gave us a great deal of concern at the time, and illustrates the necessity for extreme care when engaged in new work. When the test plant was started, only about one-fourth of the cells were in commission and for the first few days everything went smoothly. As more cells were put in service poorer results were obtained, and after a week or ten days when all of the cells were working the results were extremely poor. The current efficiency fell off to 40% and very meagre and ragged deposits of zinc were obtained.

The research staff made every effort to find the seat of the trouble, but it was a month before it was finally traced to the aluminum cathodes, with which the later cells were equipped, and which, instead of being pure aluminum, were found to contain about 3% copper. At that time no one suspected that such a percentage of copper in the aluminum cathodes could possibly affect the zinc deposit, for in the zinc process the function of the aluminum plate is similar to the function of the starting-sheet blank in copper refining. It accumulates a deposit of zinc which is stripped off when sufficiently heavy without itself taking any part in the reaction.

Also, and equally important, this operation enabled a number of men to be trained to serve subsequently as a nucleus in the final commercial plant. These men became the superintendents, foremen, and skilled operators without whom the large plant would have had hard sledding no matter how good the process and how excellent the design.

Only after all these preliminaries could the large plant be undertaken with fair certainty of success. So far the work had been under the supervision of the research engineer, but now it had outgrown the bounds and facilities of the research department. A separate organization was formed to carry out the construction and operation of the large plant, the research engineer acting in the ca-

capacity of adviser, and the men who operated the small plant became prominent members of the new organization.

Doubtless it is now apparent to you why I started out by saying that you must make your choice as to what branch you wish to follow soon after leaving school. Given sufficient ability and capacity for hard work, all the paths lead to the top, but, obviously, if you get half-way along one of these paths and decide you want to switch over to another, you will probably have to start at the bottom again.

Most large mining and smelting companies prefer to train their own men for their higher executive positions. They prefer to have men come to them while they are young and only recently out of school. The new employee's work is closely scrutinized, particularly for the first six months or a year, and his immediate superior is supposed to determine within this time whether he will fit into the organization or not. If he seems to have the necessary qualities, he is gradually given more and more responsibility and after awhile is placed in charge of investigations of increasing importance.

Now there is one thing right here that I cannot impress on you too strongly. First: Your future in the organization will depend on how well you accomplish each and every task that may be given you, however insignificant and unimportant it may, at the moment, seem to you. Second: Your advancement will depend on how well you get on with your associates and with men who may be working under you. You must cultivate a spirit of fairness and a willingness to co-operate. You must treat the men who may be working under you with consideration and must recognize their fundamental rights. No matter how brilliant and able you may be, if you are a 'crab' and constantly fighting with your associates or subordinates you will get nowhere. 'Big stick' methods are out of date. At the same time you cannot afford to allow things to be 'put over' on you. Also if, when you reach a minor executive position, you endeavor to build up your own department at the expense of another department, you are not serving the best interests of the work as a whole, and ultimately you will only injure yourself. All managers realize that a certain amount of wholesome rivalry between departments is a fine thing. The rivalry must, however, be fair and must at all times take into consideration the general good.

When you have reached the position of department superintendent, or what corresponds to it, you are the chief in your department in so far as all matters pertaining solely to your department are concerned. In such matters you have as much authority as the manager himself, and if he is wise he will carefully avoid inserting himself in any way, shape, or form between you and your men. On the other hand, authority brings with it responsibility. You must make good. You must, yourself, carry the burdens connected with the operation of your department and must make your own decisions and see that they are properly carried out. The young executive who constantly calls up his superior and asks him what

to do next instead of using his own head, as a rule doesn't last long.

The theory on which large enterprises are conducted assumes the division of the work of supervision into units, each of which is small enough so that the average man with proper training can grasp and oversee it properly and in considerable detail. The units or departments are brought together into groups or divisions and the aggregate of these constitutes the entire enterprise. The manager at the top of the pyramid is dependent for his success and peace of mind upon each and every one of his lieutenants, and the performance by him of his allotted part of the task, and so you will find that the qualities of trustworthiness and reliability are even more valued than cleverness and brilliancy.

And now, just a few more general observations before bringing my remarks to a close. Accuracy is obviously of great importance and should be cultivated to the utmost. I don't mean the kind of accuracy that insists on reporting an analysis to the third decimal place when you know perfectly well that the method you use is only accurate to the first decimal. That sort of accuracy is actually untruthful and misleading. When reporting on any phase of your work, the report should be clear and concise and, as nearly as you can make it, a true picture of what you are reporting on—well balanced and correct in its proportion and perspective.

Be enthusiastic about your work, make it your hobby—I don't mean to the exclusion of everything else. On the contrary, cultivate an interest in wholesome amusements and good-fellowship, but take an active, not merely a passive, interest in your work. Above all, don't be a clock-watcher or attempt to dole out the amount of service you give your employer according to your idea of the value of the salary you happen to be receiving. Rather, go home each day with the comfortable feeling that you have given more than value received.

Don't get the idea that everything that can be done has been accomplished and that no further improvements can be made. Realize the value of past experience, but don't let yourself be bound hand and foot by precedent. Be constantly on the look-out for opportunities to stop waste, to make use of by-products, to develop new resources, to do things better than they were being done before. Realize to start with that you can only make an exceptional success by putting forth exceptional efforts and know that "He profits most who serves best", and then, as Kipling has so wonderfully phrased it:

"If you can keep your head when all about you
Are losing theirs and blaming it on you;
If you can trust yourself when all men doubt you
But make allowance for their doubting too;
If you can wait and not be tired by waiting,
Or being lied about, don't deal in lies,
Or being hated don't give way to hating,
And yet don't look too good, nor talk too wise;
If you can dream—and not make dreams your master;
If you can think—and not make thoughts your aim,
If you can meet with Triumph and Disaster
And treat those two imposters just the same;

If you can bear to hear the truth you've spoken
Twisted by Knaves to make a trap for fools,
Or watch the things you gave your life to, broken,
And stop and build 'em up with worn-out tools;
If you can fill the unforgiving minute
With sixty seconds' worth of distance run,
Yours is the Earth and everything that's in it,
And—which is more—you'll be a man, my son!"

ALTHOUGH 85% of the world's supply of asbestos is produced in Canada, it all comes from a comparatively small district about three hours journey from Montreal, states the 'Journal' of the Society of Chemical Industry. There are fourteen principal producers, at Coleraine, Black Lake, Thetford, East Broughton, and Danville. The mining and milling of asbestos consists of quarrying proper, and the cobbing or separation of the fibre from the rock. The first operation in opening a quarry is the removal of the surface soil, usually from 5 to 25 ft. deep, for which steam-shovels are employed. The exposed rock is drilled by hand, machine, or electric percussion-drills. This is followed by blasting with dynamite, every pound of which brings down about five tons of rock. Hand-cobbing separates the crude material into three grades: (a) The long asbestos fibres and pieces of rock containing them; (b) the milling material or rock containing the shorter fibres; and (c) barren rock which goes direct to the dump. The material specified in (a) is sent direct to the cobbing-sheds, where the fibres are separated into different grades both by hand and machinery. The rock containing the shorter fibres is crushed, and the asbestos is separated from the waste by exhaust fans. The asbestos is now ready for the market, and is classed into two grades, termed respectively the crude and the fibre. The crude is divided into two grades, No. 1 having fibres over 0.5 in. long, and No. 2 containing fibre under 0.5 in. These grades are used for asbestos cloth, pipe-covering, and other articles of which asbestos is the principal constituent. The material of shorter fibre is used in other manufactures, chiefly as a filler. The production of asbestos has grown from 1400 tons, valued at £30,000, in 1885, to 120,000 tons, valued at £2,250,000, in 1919.

STATISTICS recently issued by the Bureau of Domestic and Foreign Commerce show the increase of the mercantile marine of this country as regards trade with Great Britain. The net tonnage of American ships that entered British ports with cargoes during the first three months of 1913 was 152,653; for the same period of the present year it was 534,004. It is, however, pertinent to note that the net tonnage of American ships that were cleared with cargoes from British ports during the latter period was only 238,166. One-way merchandise movement may indicate national prosperity, but it militates against the economical operation of the vessels.

CHROME-ORE PRODUCTION in South Africa during 1920 was 60,269 tons, valued at £245,378, as compared with 35,282 tons, valued at £142,541 in 1919, states a consular report.

Industrial Morale

By Richard V. Ageton

Morale has been defined as "that mental state which renders a man capable of endurance and of exhibiting courage in the presence of danger". The dictionary further informs us that the word is of French derivation and is particularly applicable to the state of mind of an army. We frequently hear references to our army of industry, or to our industrial armies, and the comparison is a very apt one when one considers the morale of each, the methods used in obtaining and maintaining this morale, and, finally, the ease with which morale can be completely destroyed.

Particular attention has been given to the morale of our armies, for a serious defeat on the field of battle would be a national disaster. It has not been until the past decade that serious attention has been given to our industrial morale; this despite the fact that a more serious disaster threatens the country, should we suffer defeat to our industrial armies.

In our army-training camps, during the late War, every effort was made to foster and support the morale of the individual recruit so that the troops as a whole would have the proper mental attitude toward their work. The medical corps, under the direction of the camp commander, made it their duty to see that the troops were furnished with proper food, sanitary camp-grounds, and orderly barracks. Numerous societies volunteered to equip and maintain suitable places and forms of amusement. Show-houses, club-houses, libraries, and pavilions were built, and many of the foremost actors and musicians of the country donated their services to carry on with the entertainment. The result of these endeavors was made evident to all of us.

In civilian life everything is different. It is our own morale which we must strive to build up and maintain; consequently, unless we receive assistance from others, we are liable to fall short of our highest attainment.

The safety engineer's work not only includes the actual inspection of working-places, with the view of maintaining safety, but in many of the smaller towns theirs is a tacit leadership in the amusement and recreation enjoyed by the inhabitants. In the larger cities they lead by suggestions that have a tendency toward the development of civic pride.

The old-time mining camp, like Topsy, "just grew". The result was fearful and wonderful to behold. String towns, three, five, and sometimes ten miles long, were built along either side of a dirty and literally stinking little creek. There was absolutely no thought of sanitation. Each individual had to care for his own water-supply, and a systematic garbage-disposal system was unheard of, unless one could call the universal practice of dumping the garbage in the aforementioned creek

systematic. Houses were placed side by side, butting into each other in such a manner that privacy was impossible; modern two-story dwellings side by side with two- and three-room shacks, built from the leavings of the mine-timber dumps; no trees or grass plots, except an occasional one around the company's office. The food-supply was in many instances nearly impossible. If more than one company were operating in the town, one had to trade at the store operated by the company for which he was working, or "get his time". Such were the conditions to be endured by the married miner; for the

AN OLD-TIME MINING CAMP

single man, there was the choice of living with one of these families, or in the company's boarding-house. Many of the children, owing to their environment, were unclean and sickly. The public schools, when they had such institutions, were held in buildings that no longer would serve for any other purpose.

The disorderliness of the town was reflected in the mines. Costly and intricate pieces of machinery were housed in ramshackle buildings, little care or attention being given to their up-keep until they wore out through misuse, when they were replaced; a costly procedure for the mining company. The dry-house or change-house consisted, in many individual cases, of two or three nails driven up behind the boiler in the vain hope that one's clothes would dry over-night. The tools, such as drilling-machines, saws, axes, shovels, picks, and drill-steel, were more often to be found in the waste-piles than at the working-places; and everywhere one found a tired, disgruntled, and decidedly discouraged bunch of men. They would come to work tired in the morning; would put in most of their time grumbling at the lack of tools, lack of air-pressure, lack of ventilation, or general cussedness of the shift-boss, as the case might be; working along so as barely to exceed the minimum acceptable amount of work necessary to draw a day's pay; and go home no more tired than they came to work in the morning. In the

evening, for rest and relaxation, there were the saloons, gambling-houses, or similar forms of amusement. There was no thought of the morrow, or if at all it was to find forgetfulness of the work and surroundings, if only for a few moments.

This program would be continued day after day, until, if the miner were single, he would leave for some other camp; eventually developing into a 'tramp' miner, or 'ten-day' man. The tramp miner is, in many instances, a good miner and the only thing to be said against him is that he does not stay long enough to become acquainted with the company's methods of operation; consequently it never receives as much value from him in return for the money invested as it would were the company to de-

He goes to work from a clean home, or an equally clean boarding-house; changes clothes in an airy and well-appointed drying-chamber; and goes underground with the impression that the surface conditions around the mine are clean and orderly, and consequently he will unconsciously try to maintain those same conditions underground. Arriving at his working-place he finds his tools sharpened and the shift-boss has a 'Good morning' for him. Things begin to pick up, even for the tramp miner; he can do more work with less effort, and the funny part of it is he will do more and better work; he has a high morale.

When he goes off-shift he again changes his clothes, hangs up his digging-clothes in the locker or on a chain, sure that they will be dry for the morning.

The care of the injured miner has always received more or less attention. Nowadays the miner in such a mine knows that every precaution has been taken to prevent his being hurt, but, that should an accident happen, every arrangement has been made to take care of him. Perhaps he himself has been instructed in first-aid and mine-rescue work; in any event, some one working near him has, as it is a rule in many larger mines that at least 20% of the men must have had first-aid training. Arriving at the surface, he is immediately taken to a dispensary, where his dressings are completed

A MODERN CHANGE-HOUSE

velop in him a desire to remain in that particular locality.

If the miner were a married man with responsibilities that would not allow of his leaving for other camps, he would often develop into a chronic grouch and kicker. Frequently such men were the only ones available for the positions of less responsibility and their disgruntled attitude was reflected by all the men under them with whom they came in contact.

In the army we would say that an outfit in which conditions approximated those just described had a decidedly low morale.

Imagine then the difference in the mental attitude of a miner, both toward his work and his home life, when living in a town such as the one just described and when living in a town where the operating company has taken pains and care to build clean well-appointed houses; where there are wide and well-lighted streets; where the sanitary conditions are good; where the water is clean and purified before it is allowed to enter the mains; where the disposal of garbage is a daily ritual; where the supply of food is the best; and where the best obtainable instruction and care is given to growing children.

by a nurse, and, in some instances, a physician; and from there he goes to a hospital. In many cases the nurse on duty at the dispensary, called the visiting nurse, looks to the health and welfare of the miner's family, thereby relieving him of worries in that respect.

In the evening, after work, he has at his disposal a club-house, where he will be sure to find some congenial soul ready for a game of pool, or a good talk. If he so desires, he can go to the company's library, where he will find many books dealing with any subject in which he may be interested. In the club-house there is generally a room that is used for motion-pictures, open to the public. Two or three times a week in the summer the town band will give concerts in the park, and in the winter there are dances.

The old adage, that "all work and no play makes Jack a dull boy" is applicable to all lines of industry, but especially to mining, where one spends practically one-third of his time underground. Many of the safety engineers appreciate this fact and act accordingly.

The Chambers of Commerce, in the more progressive mining camps, realizing the call of youth for more and

diversified forms of industry, are inviting the establishment of factories in order that both the younger and older generations may find congenial employment and remain at home.

Of course, neither of the conditions described are to be found in their entirety in any one mining camp. However, in the old days there were more camps to which the former description would apply. Nowadays conditions are rapidly changing, and there are many camps to which the latter description could be applied. A visit to one of these newer camps is indeed a revelation and they must be seen to be fully appreciated.

Industrial morale, then, is obtained and maintained by the proper attention to the miner's work, his living accommodations, and his recreations. Regarding the first, he will generally accept dictation from the company, as he feels that this is the company's right, as they pay him for his work. Any interference with his home life, living conditions, or recreation is a subject rife with trouble. Too often the choice of the occupant for the safety engineer's position has not been a happy one, as he has sometimes left the impression that the company was adopting a patronizing or charitable attitude toward the miner. This was regrettable, for the subject must be approached from the right angle of pride in their work and pride in the town.

Mining in Bolivia

Bolivia is the third largest of the South American republics, states a consular report, having an estimated area of 708,195 square miles; some of the frontiers have not yet been definitely established so that the exact area is not known. It has an estimated population of 2,820,000, or about four persons per square mile, being one of the most sparsely settled of the South American countries. About 80% of the population is said to be native Indian, 10% mixed blood, and 10% white, of Spanish descent. Most of the population is found in the plateau region, which covers an area of about 40,000 square miles and lies at an elevation of 12,000 ft. above sea-level.

La Paz, with a population of 107,000, is the seat of government, is the largest city and most important distributing centre in the country, and has an elevation of 12,000 ft. above sea-level; Oruro, with a population of 31,360, is 12,000 ft. above sea-level, is the centre of the mining district, and ranks second commercially and as a distributing centre; Potosi, with a population of 30,000, lies at an elevation of 13,000 ft., and is immediately surrounded by important and productive mines for which it is the distributing centre; Cochabamba, with a population of 30,800, lies on the eastern slope of the Andes, 8000 ft. above sea-level and, being the terminus of the railway, is, to a certain extent, the distributing centre for eastern Bolivia, though most of the imports for that region are brought in through Brazil and Argentina; Sucre, the nominal capital of Bolivia, has a population of 29,437, lies on the eastern slope of the Andes at an elevation of 8500 ft., and is of little commercial importance; Santa

Cruz, with a population of about 30,000, is in the low lying region of eastern Bolivia at an elevation of 1500 ft., and is in the midst of a region that has a great agricultural future, but at the present time, owing to lack of transportation facilities, is cut off from the rest of the world.

The principal wealth of Bolivia at the present time is its mines of silver, tin, copper, wolfram, antimony, and bismuth. The principal exports are tin, rubber, copper, silver, bismuth, wolfram, antimony, lead, and wool. The principal imports are machinery, foodstuffs, live stock, and textiles. The normal rate of exchange is 2.57 bolivianos to the dollar. Bolivia is not a country that could live on its own resources; therefore, its foreign trade is of vital importance. There is no home market for its mineral production, practically all of which must be exported. Few manufactured articles are made in the country and not enough foodstuffs are produced to supply the home demand, so that for both manufactured articles and foodstuffs it is dependent upon imports. It has no direct outlet to the sea, so that all its foreign trade must go through the four surrounding countries, Peru, Chile, Argentina, and Brazil. A greater part of both the exports and imports passes through Chile, which offers the best transportation facilities, and the shortest and easiest outlet to the sea. Great Britain in 1919 still held first place in Bolivian export trade, taking 31% of the volume and a little over 49% of the value. The principal articles exported to Great Britain were tin and silver. The United States, which in 1913 held sixth place, has held since 1915 second place in the export trade. In 1919 the United States took 45% of the volume and 41% of the value of the entire export trade of Bolivia. The principal articles purchased were tin, valued at \$16,186,798, and rubber, valued at \$2,660,110. Tin has always occupied the most important position, representing, in 1913, 72% of the value of all exports and, in 1919, 69% of the value of all exports. Until about 30 years ago silver was the chief article of export; but, since the development of the old silver mines as tin mines, silver is no longer of such importance, though it is still a leading industry of the country. During 1919 tin ores, concentrates, and bars valued at \$3,794,363 were purchased by the United States. This item is greatly in excess of any other item of export. Copper ore ranked next in importance, and wolfram held third place. Very little wolfram- or tungsten-bearing ores have been exported during 1920. Silver products held fourth place in point of value.

TO PROVIDE FUEL for the use of the Alaskan Engineering Commission, coal mining was continued in 1919 in the Matanuska field, Alaska, on about the same scale as in previous years. Near this field and also tributary to the Government railroad, is the Willow Creek gold district, where large auriferous lodes are being exploited. These mining developments are described in a pamphlet by Theodore Chapin entitled 'Mining in the Matanuska Coal Fields and the Willow Creek District, Alaska,' issued by the U. S. Geological Survey, Department of the Interior.

Sampling of Bullion

By R. R. Kahan

*The three methods of bullion sampling that are commonly employed are: (1) by means of a dip-sample; (2) by means of clip- or chip-samples; (3) by drilling the bar.

DIP-SAMPLES. If the bullion is melted at the correct temperature and properly stirred, the dip taken should represent the mass of the bullion, provided the bullion is poured immediately after dipping. This is important; there should be no time for further refinement of the bullion by the fluxes, or reduction of oxides by the plumbago crucible. The dip-sample may not represent the mass of the bullion because, compared to the resulting bar of bullion, the dip has a large surface; oxidation has a greater effect on the dip than on the bar during the time that elapses before quenching. Again, if the oxides are dissolved in quenching, the dip is partly refined; if the oxides are not dissolved, the dip is debased. A little slag adhering to the dip will vitiate the assay if not carefully removed from the assay piece.

CLIP- OR CHIP-SAMPLES. These can only be taken from bullion which is homogeneous; if any liquation has taken place they are unreliable. As a preliminary to taking the sample it is advisable to clean the outer surface of the bar with a file or scratch brush; the sample should be taken over a moderate depth and large area.

DRILL-SAMPLES. These are similar to clip-samples, but are more difficult to take, particularly when a large number has to be taken. Unless great care is exercised contamination is liable. Drill-samples are suitable in the case in which a bar is suspected of being non-homogeneous, and which it is not convenient to re-melt. A sufficient number of samples can be made to give a fairly accurate result.

No single method of sampling is applicable to all classes of bullion produced. A dip-sample usually gives a slightly high result, and a clip-sample a slightly low result; drill-samples are not used to any extent where large numbers of samples of all classes of bullion are taken. The word 'slightly' has been used because it is only by examining a large number of results that the difference can be noticed. With fine gold it is a different matter, as it makes no difference if a dip-, clip-, or a drill-sample is taken, provided all precautions are observed with each kind of sample.

At the proposed refinery the bar will be melted with suitable fluxes; when at the correct temperature it will be thoroughly mixed with a specially shaped plumbago stirrer, which has the effect of lifting the molten metal from the bottom of the crucible, not simply setting up a circular motion in the molten metal. Dip-samples will then be taken with a dipping-iron so constructed that the samples will be taken simultaneously from different

depths of the molten metal. The dips will be quenched in water, and the bullion, after pouring into ingots of 300 to 350 oz., will be quenched in water slightly acidified with sulphuric acid.

The bars, after cleaning, will be sampled in the presence of two persons, by taking clip-samples from different ingots. Half the number of clip-samples and half the number of the dip-samples will be sent to one assayer, and the remainder of the samples will be sent to another assayer. Each assayer will obtain his results by using different furnaces, different apparatus, and even different methods of weighing, and different proof gold for obtaining the surcharge corrections. In fact, the assay reports will be obtained in different assay offices using methods as different as is possible in bullion assaying. Then if, when the reports by each assayer are finally brought together, it is found that the clip-assays agree within limits, and the dip-assays agree within limits, and finally if the mean of the clip-reports and the mean of the dip-reports agree within certain limits, the mean of the clip- and dip-reports is taken as the fineness of the bar. If for any reason the assay report on any sample is suspected of being inaccurate, a repeat assay is made on the same sample; and if the inaccuracy of the original report is confirmed, the new result is substituted before obtaining the final result.

When the various assay reports considered do not agree, the bar is subjected to further treatment, which may consist of re-melting the bars or of subjecting them to a preliminary refining. Generally, when concordant assay results are not obtained, the cause is due to the presence of an excess of base metal, which must be removed; this is done by preliminary refining. It is important to notice that reliance will not be placed entirely on dip-samples. The dip-samples become separated from the bars before final dispatch to the assayers, and there are possibilities of transposition. Clip-samples are always sent in conjunction with dip-samples, so that an error of this nature is easily detected.

I agree with the suggestion that, with the establishment of the Rand refinery, an effort should be made to standardize methods in all assay offices. It may be taken for granted that the refinery staff will at all times be prepared to discuss standard methods. A portion of the equipment of the refinery consists of sets of troy weights and assay weights standardized by the National Physical Laboratory; in due course it should be possible to arrange for the periodical checking of weights. Also the refinery will have a fine-gold trial-plate certified by the Board of Trade, England.

The refinery will use platinum parting trays to part 72 assays at one time. With platinum at £26 per ounce such a tray, without the cups, cost £257; a full set of 72 platinum cups for such a tray costs another £221. A satisfactory arrangement is to have a platinum tray and silica cups. The silica cups cost about 3s. each, against, say, £3 each for platinum cups, and are probably better for working; the gold cornets never adhere to the silica as they sometimes do to the platinum.

*Abstracted from a contribution to the discussion of a paper on the subject, read before the Chemical, Metallurgical & Mining Society of South Africa.

REVIEW OF MINING

COST OF RE-TREATING CALUMET & HECLA TAILING

According to a recent report the Calumet & Hecla Co. is in position to make 1,500,000 lb. of copper per month at a cost not in excess of 7c. per pound at its 'reclamation' plant. It is in this department that the sand from Torch lake is treated—sand that in the 50 years of mining prior to 1915 was considered waste and was discarded. It averages over 10 lb. of copper per ton, but in the old days when Calumet & Hecla was mining 'rock' that ran 50 to 100 lb. per ton and above, it was not considered worth saving. In 1913 when the company began to prepare for the treatment of this sand, its engineers estimated there was 40,000,000 tons on the lake bottom which would yield at least 500,000,000 lb. of copper; or, based on a treatment of slightly under 4000 tons per day, it would take 30 years to exhaust the deposit.

In 1920 over 1,378,000 tons of this sand was treated, an average of 3775 tons daily, resulting in a production of 14,138,240 lb. of copper, or an average of 10.26 lb. per ton of sand. This metal was recovered at a total cost of but 6.6c. per pound, or 1c. per pound less than in the preceding year. In 1915 when operations were first started, 181,732 tons was treated, producing 1,582,000 lb. of copper at a cost of 4c. per pound. The following table shows the record to date:

	Sand treated, tons	Production, lb.	Production, lb. per ton	Cost ¢ lb.
1920	1,378,500	14,138,240	10.26	6.6c.
1919	915,659	9,082,952	9.92	7.6
1918	715,007	9,245,388	12.93	7.2
1917	730,543	9,075,457	12.42	5.9
1916	545,727	5,412,049	9.92	4.5
1915	181,732	1,582,802	8.71	4.0

NEW RAILROAD WILL STIMULATE PROSPECTING IN ONTARIO

That the Ontario government will give substantial aid to the construction of the Northern Light railway is regarded as certain, the only question being whether it will take the form of a subscription to bonds or a straight cash bonus. The matter is under consideration by the Cabinet and a decision is expected in about two weeks. In the meantime 13 miles of the route through the townships of Teck, Lebel, and Ganthier, in the Kirkland Lake district, have been surveyed. The probability of the construction of the road has given a great impetus to prospecting, and many claims near the projected route which would have been of little value without transportation are being staked. A rush of prospectors has set in to Holmes Township, 20 miles west of Kirkland, on the proposed line where a discovery of gold was made last fall.

ARIZONA

Chloride.—The most recent report of S. F. Eaton, superintendent of the Dardanelles mine, says "further work on the new ore-shoot to the extreme north shows a foot-wall streak of quartz averaging \$40. One lense toward the hanging wall assays over \$300. A raise has been driven 15 ft. on the foot-wall and some lateral work has been done here. We have ore in both these faces. The vein shows a distinct split on the level just beyond this raise and we are now driving north to determine its course. Ore-platforms are

practically full and we will soon have to build an addition. We have on hand nearly \$2000 worth of shipping ore. Arizona copper-smelters having closed down for the time being it is best to hold this ore. The total cost of freight to and treatment at a Utah smelter would be nearly \$30 per ton. This decreases our profit on \$45 ore from \$30 to \$15 per ton. For this reason we are accumulating shipping ore at the surface and in the mine, thus building up a tangible liquid asset which can be realized on as soon as the Arizona smelters resume operations.

Jerome.—The passing of its dividend for the second quarter of 1921 by the United Verde Extension company was not necessitated by the condition of its treasury. With about \$3,000,000 government bonds and \$500,000 cash the financial position of the company is at once apparent. It also has coming due within the next few weeks some \$300,000 for copper sold, while other items swell the current assets to above \$5,000,000. And by including its copper surplus, running above 20,000,000 lb., the company has another current asset which would increase the total to around \$8,000,000. United Verde Extension fared relatively well in May, with sales aggregating 5,000,000 pounds.

Oatman.—Fire swept the town on June 27, leaving only half a dozen buildings standing among the smoldering ruins of the commercial district. The damage will run from \$250,000 to \$500,000, with practically no insurance. None of the mines or mine buildings was damaged. Important among the business houses burned were: St. Francis hotel, Grimes hotel, Oatman hotel, Kittlegon hardware store, Farrow-Stockpool Auto Motor Co., Fisher building, garage, ice-plant, Oatman Theatre, and numerous warehouses. The fire was discovered at 2:15 p.m. in the annex of the St. Francis hotel, and it spread to adjoining buildings, most of which were structures of from one to three stories. As far as is known no lives were lost, but several persons were painfully burned.

Oatman.—Operations are to be resumed by the Nancy Lee Mining Co. The main vein is opened by an adit from which \$20 ore was stoped some years ago. A compressor will be installed for the work about to be done.

Pearce.—Floyd Rash and Joe Mathews have opened a large body of high-grade silver-lead ore in the mine owned by George Blignon and Joe Dickstein, which they are working under bond and lease. Two cars of \$50 ore have already been saved. The mine is 15 miles from here and adjoins the old Golden Rule property.

Tucson.—T. H. O'Brien, general manager for the Inspiration Consolidated company, expresses the belief that the mines of the company will not be re-opened before the first of next year. He is quoted as saying:

"Our company at Inspiration is at present developing the west orebody known as the Live Oak. We are preparing to sink the Live Oak shaft as well as the Porphyry shaft of the Porphyry Consolidated Copper Co., which we recently acquired and which will connect up with the lower levels of the Live Oak orebody."

CALIFORNIA

Angels Camp.—The Carson Hill Gold Mining Co. has established a new record for ore treated. During the month

of May 15,070 tons of ore was crushed in the 30-stamp mill, making an average stamp-duty of 18.5 tons per stamp. The sinking of the Melones winze below the 3500-ft. level is progressing steadily.

Carrville.—Axel Carlson and Julius Love have taken a contract to drive a 1200-ft. adit and a 400-ft. raise in the Golden Jubilee mine on Coffee creek. The property has recently changed hands and the new owners plan energetic development.

Colfax.—The Rising Sun Consolidated Mines Co. has suspended production and will unwater the mine below the 700-ft. level. Sinking will be resumed in the main shaft.

Placer operations at the Glenn mine, six miles east of Last Chance, are giving good returns. Owners state that 100 carloads of gravel, of an estimated value of \$20 per car, have been extracted this season. About 8000 ft. of tunnel and drifts has been driven by the present management.

Grass Valley.—After six years of work, during which \$600,000 was spent, the Grass Valley Consolidated Mines Co. has decided to abandon the Allison Ranch mine. The pumps are being withdrawn and the mine will fill with water.

W. S. Tevis, prominent San Francisco capitalist, has acquired a large interest in the Alcalde gold mine, situated about four miles below Grass Valley. Preparations are being made to sink a vertical shaft and for installation of a modern mine-plant.

The Mineworkers' Protective League has offered to accept a reduction of 50c. per day in wages, but refuses to consider the \$1 cut made by the operators. Conferences are being held in an endeavor to reach a compromise and prevent a threatened walkout. Many of the leading companies have already cut their forces and are apparently preparing for a total suspension of operations.

Hayden Hill.—H. P. Andersen, owner of the Consolidated mine, situated near the Juniper, where rich ore has recently been found, announces that he will commence development on his property.

Murphys.—E. C. Norris, of Los Angeles, states that he has \$400,000 available for the development of the Murphys Flat and Ora Plata mines. It is planned to run a long adit from the San Domingo side of the hill.

Redding.—Rehabilitation of the famous Black Bear mine, near Yreka, has been undertaken by F. A. Gowing of Piedmont and associates. The old tunnels are being cleared and the surface equipment overhauled. The Black Bear was a prominent producer of gold in the pioneer days of Siskiyou county and for several years was one of the leading gold mines of California.

IDAHO

Coeur d'Alene.—Another find that may prove important is reported in the Alhambra mine. The shoot is said to be three feet wide, showing high-grade gray-copper ore, on the hanging-wall side, which is about 20 ft. wide. The east drift on the property is some 4000 ft. long and in that distance three different ore-shoots have been cut. One shoot, 200 ft. long, carrying gray copper, was opened some time ago and another shoot 40 ft. long was exposed recently. The company is overhauling its mill.

Galena ore has been found in the property of the Red Monarch Consolidated Mining Co. adjoining the Callahan in the Beaver district. The body is said to be 22 in. wide. At the point of discovery its width was little greater than that of a knife-blade. The winze followed ore for 15 to 20 ft. Development was started at a point 50 ft. from the main cross-cut. This is at a depth of 1000 ft. and near the 2900-ft. point in the tunnel.

George Austin, manager for the Rainbow Mining & Milling Co., has let a contract for 50 ft. of sinking on a showing of silver-lead-zinc ore at a point in the tunnel 250 ft. from its portal. The company also will raise on copper ore ex-

posed in the last 200 ft. of drifting to a point 1300 ft. from the portal of the tunnel.

The Rex Consolidated Mining Co. is proceeding with the development of its property in the Nine Mile section, according to E. P. Murray, superintendent. A drift on the Okanogan vein has been advanced 60 ft. at the 400-ft. depth.

MICHIGAN

Houghton.—The Quincy is one mine that will be in splendid shape to resume operations when the copper market revives. With the improvements that have been made in the mills and smelters, and underground conditions never better, Quincy will be in a position to effect a considerable saving in cost. Quincy's new furnace, having a capacity of 150,000 lb. of copper daily, will be completely equipped within a month's time. It has been partly in use, but its casting equipment has not been wholly installed. The furnace is of a type similar to those in use at the Michigan and Calumet & Hecla smelters, with certain improvements which contribute to economy of operation. All material to complete the furnace is on the ground, but the work is being proceeded with leisurely, as there is no particular necessity for speed.

In the milling plant all but one of the five units have been equipped with re-grinding machinery, which resulted last year in a 10% saving, increasing the copper yield by that much. The one unit not so equipped has been re-modeled, however, and is ready for the installation of re-grinding equipment.

Underground, Quincy 'rock' is showing increasing richness with depth. Advantage has been taken of the lull in the copper demand to extend the openings and deepen the shafts, and the mine now perhaps is more extensively opened, so far as new drifts are concerned, than ever before. Last year the tenor of the 'rock' stamped was 7.36% higher than that treated the preceding year.

Progress is being made with the Calumet & Hecla geological survey, although it is yet too early to say whether or not its objective will be reached. A corps of eminent geologists and mineralogists are engaged in this research, which is primarily to discover, if possible, the origin of the Lake Superior copper deposits and the manner in which they were laid down. Many data are being collected, not only in the mines of the Calumet & Hecla, but in other properties of the district. It is possible that before the investigation is completed that old theories will be shattered. It is the hope of Calumet & Hecla to establish certain fundamental facts that will greatly aid in the uncovering of new copper deposits, thereby doing away to a large extent with the present hit-or-miss methods of exploration and development which have proved so costly in the past.

No metal to speak of is now moving out of the district. No new orders have been received of late and practically all copper heretofore ordered has been shipped. Calumet & Hecla has one carload of wire bars to go out to a Middle-West concern, consisting of 80,000 lb. This completes all of its metal orders. Twenty-five men were laid off at the Calumet & Hecla smelter this week, but about 200 are still employed. Seven furnaces out of twenty-four are in operation, but it is possible that some of these will be shut-down. The depression in the district caused by the closing of the majority of the mines has given an impetus to farming and many new farms are being started. It is estimated that 500 new farms will have been taken up here this year.

MONTANA

Deer Lodge.—The new ball-mill in the concentrator at the Champlon mine of the Butte-Jardine company is grinding 125 tons per day. The plant is equipped with Dorr classifiers, Janney flotation machines, and a Portland filter. The concentrate averages \$280 per ton. Ore rich in silver has been entered in the face of the 1700-ft. tunnel.

Jens.—At the Forest Rose mine, owned by the Butte & Western Mining Co., sufficient ore has been developed to warrant the erection of a concentrator. In addition to second-class ore some high-grade is being saved.

Libby.—Oscar Nordquist, superintendent of the Lukens-Hazel mine, has purchased a new pump which will be installed in the shaft at a point about 50 ft. below the main tunnel. Sinking is progressing at the rate of about 2½ ft. per day.

Nelhart.—Ore is being shipped from the Hartley mine and from the Ludlum mine, being operated by L. Heltman. Lessees are at work at the Big Seven and Galt properties.

NEVADA

Arrowhead.—Ore 8 ft. wide and estimated to be of mill-grade for this width, with an 8-in. seam of rich material, has

Leadville.—The fourth shipment of concentrate has been made by the Leadville Mines Co., operating in northern Washoe county, 40 miles from Gerlach, on the Western Pacific. The concentrate is sent to the Western Ore Purchasing Co. sampler at Elzen. These shipments average about 225 oz. silver and 500 lb. lead per ton, and the net value of each shipment is \$6500 to \$7000. The mill heads assay 20 oz. and, treating 30 tons of ore daily, three tons of concentrate is produced. An electric locomotive is used to haul the ore through a 1700-ft. tunnel to the mill. The ore is a sulphide that is treated by flotation.

Round Mountain.—The second shipment of bullion from the Round Mountain placer mine was sent to Tonopah a few days ago. It had an estimated value of \$21,000.

Silverhorn.—A new find of ore that assays \$42 per ton across two feet has been found near the south boundary line

Nordberg Blowing-Engine at the El Paso Smelter

been found in a winze at a depth of 380 ft. in the Arrowhead, the greatest depth at which work has been done. The winze is being sunk a short distance west of the shaft.

Goldfield.—Donald and Giles, Florence lessees, now have exposed in the hanging wall of the Reilly stope a 12-ft. shoot of ore. This ore is on both walls of a vein about five feet wide, with a 3-ft. width of gangue between. The last samples taken gave: Foot-wall, 10 in., from face of drift, \$536. Hanging wall, 16 in., \$112; 2 in., \$11,000. An assay taken over an area of 5 by 1 ft. in the back of the drift gave \$480; 8 by 1 ft., \$2744; 12 ft. by 6 in., \$142. The \$11,000 ore is being sacked for shipment to Selby. The ore is at a depth of 265 ft.—The Silver Pick has opened a promising orebody in the foot-wall of the Red Top vein in ground leased from the Consolidated. About 30 tons of ore estimated to average \$50 to \$75 per ton has been broken in a 35-ft. drift. The find was made at a depth of 265 feet.

of the Silver Dale group, about 600 ft. south of the Huson shaft, where the first rich ore was found. Development is now under way to determine if the new find is on the extension of the main vein, or on an entirely different one. Development continues in the north cross-cut on the 50-ft. level of the Huson shaft and in the tunnel below which gives 100 ft. of 'backs' on the vein.—Ore running from \$11 to \$14 per ton is reported from the Nickel group of the Silver Horn Mining & Development Co., controlled by Robert Mulford, of New York.

Spring Valley.—Rich silver-gold ore has been found in a new district called Millick, in south-eastern White Pine county. The find was made by John D. Tilford on claims in which Richard and Arnold Millick and John Krotzer are interested. There has been a rush into the district and hundreds of claims have been located. The rich ore was found on the surface.

Tonopah.—The 50-ton mill of the Consolidated Spanish Belt has been nearly completed, 45 miles north of here and near Manhattan. Wet concentration and flotation will be the processes used in treating ore containing silver, gold, copper, and lead. The ore, after passing over the concentrators, where tests indicate 60 % of the metallic content will be recovered, will be treated by flotation. The crushing equipment consists of ten 1050-lb. stamps. The nearest railroad point is Tonopah and all of the mill machinery was hauled from here. The mine is in condition for a steady production of ore from the workings above the main tunnel, which connects with the 525-ft. San Pedro shaft at 2400 ft. from the portal.

A 3 to 4-ft. width of 125-oz. ore has been opened in the Olsen lease on the Halifax at a point a short distance above the 1000-ft. level. A 1-ft. width assays \$750. This is said to be the highest-grade ore ever found in equal quantity in the eastern part of the Tonopah district and if it develops to be more than a nocket it will mean a big jump eastward for the line of the proved ore-zone.

Fifty State policemen, 25 of them in uniform, arrived from Reno on June 27 to assume charge of the strike situation here. The police were sent following complaints by the Tonopah Belmont and Tonopah Extension mining companies that their men have been frequently assaulted and intimidated. They have a total of 350 men working. Governor Boyle notified the mine-owners that the workers are entitled to protection and the State will see that it is given them. Miners and millmen are said by the owners to be arriving in Tonopah to act as strike-breakers. The strike has been on since April 16.

Virginia City.—Guided by R. H. Elliott, Western manager for the Metals Exploration Co., and with Henry Rives, secretary of the Nevada Mine Owners' Association, Roy Hardy and Edward Higgings, of the United Comstock Mines Co., and G. H. Hutton, manager for the Canyon Dredging Co., sixty members of the San Francisco section of the American Institute of Mining Engineers visited the project of the United Comstock Co. on the American Flat, south of Gold Hill and the gold-dredging operations near Dayton on June 27. A business meeting at Minden and a visit to the North End mines completed the program.

UTAH

Alta.—R. O. Dobbs, manager of the Louise mine, states that high-grade ore has been cut in the connection made between two raises from the Maggie tunnel. The ore, which is galena, lies along the Cardiff overthrust between the Defiance fissure and a minor fault. On June 21, the first train to arrive in camp over the Little Cottonwood Transportation line marked the beginning of the shipping season of 1921.

American Fork Canyon.—John Cleghorn, manager for the Globe Consolidated Mining Co., announces that operations have been resumed. Last season, 550 ft. of development work was done. In the No. 2 fissure, a small quantity of ore was uncovered last year that averaged 99 oz. in silver, \$1.80 in gold, and 72 % lead.—Excellent progress is being made in driving the Holden tunnel by the American Leasing Co., which is developing the Bellerophon and Live Yankee properties, according to C. B. Ferlin, manager. The company is driving the tunnel to cut the downward extension of a rich shoot opened last year in a raise.

At the Pittsburgh mine, in the main canyon, a force of men is cleaning up the workings, preparatory to resumption of development. W. J. Cralg is in charge of the work. This property is at an elevation of 10,200 ft., and there has been snow on the ground until recently.

Eureka.—The directors of the Tintic Standard Mining Co. have declared a dividend of 5c. per share, payable July 9 to stockholders of record July 1. Last quarter the same amount was distributed. This disbursement will bring the

grand total of dividends to \$1,538,332.—Ore shipments from this district for the week ending June 18 totaled 137 cars, of which the Tintic Standard shipped 49; Chief Consolidated, 39; Dragon, 14; Eagle & Blue Bell, 7; Iron Blossom, 6; Iron King, 6; Colorado, 5; Mammoth, 4; Victoria, 4; Swansea, 4; Eureka Mines, 1; Martha Washington, 1.

A night shift, consisting of 50 men, has been put on at the Blue Bell and Victoria mines, owned by the Bingham Mines Co. This action followed the announcement by the American Smelting & Refining Co. that it would again receive ore from these two mines. Late in March, the mines were informed that only 50 tons of ore per day would be accepted. It is stated that some of the richest silver-lead ore ever opened in the Tintic district is now exposed in the stopes of the two mines, but on account of the low price of lead, this ore has not been marketed.

Mining operations were started in the Swansea Consolidated property by the Tintic Milling Co. on June 19, according to Theodore P. Holt, superintendent for the latter company. For the past two months a force of men has been repairing the shaft down to the 500-ft. level of the Swansea, and an electric hoist and compressor have been installed. The first work will be on the 500-ft. level, where there is said to be a large tonnage of milling-grade ore.

Rapid progress is being made in the sinking of the shaft at the Independence mine, in the eastern part of the district. During the first twenty-one days of June, the shaft was sunk 72 ft., with but one shift employed. The shaft is now at a depth of 400 ft., and will be sunk to the 500-ft. level.

Moab.—W. S. Skelly and associates of Salt Lake City are at Cisco, making preparations to start operations on the placer properties there. Operations will be undertaken on the Butte and Helen claims. The intention is to put in a Walling machine, with a capacity of ten tons per hour. The sand is said to average 90c. in gold and 70c. in platinum.

Ophir.—James Worthing, superintendent of the Ophir Silver mine, reports that the shoot of shipping ore in the second Buckhorn fissure has widened and grown richer. The ore averages now \$50 per ton. A new compressor is being installed.—At the Ophir Hill Consolidated property, about 150 men are now employed in the mine and mill. One carload of high-grade ore is being mined per day, while the concentrate from the mill is being stored.

Park City.—Shipments of ore from this district for the week ending June 18 totaled 887 tons, as against 1109 tons for the preceding period. The Judge companies shipped 382 tons; Ontario, 286; and the Silver King Coalition, 269.

Salt Lake City.—Ernest Bamberger, general manager for the Ontario Silver Mining Co., returned on June 20 from Washington, D. C. Mr. Bamberger attended a conference there, at which were present representatives of the lead mining and smelting industries, regarding tariff on lead ores, lead in copper-matte, and other forms. He feels confident that favorable tariff legislation will be passed early in July which will terminate the dumping of foreign metals and other raw materials in this country. Mr. Bamberger stated that during April, 12,000 tons of shrapnel was imported under the guise of type-metal, paying the low duty of 15 % ad valorem. This material is not type-metal, but an antimony-lead alloy. This, he believes, in part explains the recent drop in the price of lead.

In spite of the protest of the Utah Chapter of the American Mining Congress and numerous citizens against granting permit to sell 467,100 shares of stock of the Bingham-Galena Mining Co. at a maximum price of 75c. per share, the State Securities Commission granted the permission for such sale. The decision marks the end of one of the most hotly contested cases in the history of the Commission, and the opposition was based solely on the fact that George Graham

Rice and his associates are to have charge of the selling of the stock.

WASHINGTON

Northport.—The Keystone Lead Mining Co. has been organized to develop property consisting of a group of 12 full claims adjoining the Electric Point mine on the east.

Springdale.—Sacked silver ore from the Queen and Seal mine in the Deer Trail district is being stored here pending shipment to the smelter. The ore is high-grade and hand-sorted, and is being delivered by auto-truck at the rate of five tons per day.

WISCONSIN

Benton.—The Nightingale Mining Co. has shut-down its mine on account of the constantly decreasing price for ore.

furnaces, twelve double compartments to the block, are kept warm. Shipments of the manufactured product are made but in smaller volume than has been customary in other years.

Livingston.—The Yewdall mine, operated by the Vinegar Hill Zinc Co., is producing weekly about 300 tons of 30% zinc concentrate, this ore all going to the National Zinc Ore Separators, at Cuba City. The ore is burned for sulphuric-acid base, and the high-grade blende recovered is being stored, there having been no shipments of 'commercial' zinc ore in two months. At the sulphuric acid plant in Cuba City improvements in methods have raised the grade of the acid, so that shipments are made weekly of three 40-ton tank-cars of 66°B. A shut-down in the plant will be ordered shortly and additional installations will increase the plant

Unloading-Bridge at the Utah Copper Co.'s Leaching-Plant at Garfield

Latest quotations put 60% zinc concentrate at \$20 per ton. The average zinc concentrate for the district is about 30%, and at ruling quotations such ore would bring less than \$10 per ton. A discovery of carbonate zinc ore, sphalerite, and lead ore was made recently on the Sally Waters tract. The property is being developed and will be equipped and ready to ship ore when the markets improve. Robert McGulre, of Benton, is in charge.

Day Siding.—The North Unity mine of the Vinegar Hill group is operating steadily. Shipments have been regular until quite recently. The mine is regarded as one of the best zinc producers in the field.

Highland.—Mining properties owned by the New Jersey Zinc Co., have been leased to local operators, who are mining for carbonate-zinc ore. The New Jersey Zinc Co. has practically abandoned most of its mining properties in the Wisconsin zinc-lead district.

Mineral Point.—Operations continue at the works of the Mineral Point Zinc Co., on a restricted schedule. The sulphuric-acid plant is shut-down but two blocks of zinc-oxide

capacity 25%. When running full blast, this acid plant will produce 100 tons of acid per 24 hours.

BRITISH COLUMBIA

Barkerville.—Hydraulic mining has been started at the Waverly, Lowhee, and First of May properties. John Hopp and associates are working on the Mosquito, and will start hydraulic mining shortly.

Nanaimo.—A branch of the Canadian Institute of Mining and Metallurgy has been formed here, and the following officers have been elected: George O'Brien, chairman; F. A. Spruston, vice-chairman; W. H. Moore, secretary-treasurer; John Johns, C. M. Campbell, C. Graham, and J. Strang, council.

Sandon.—The milling capacity of the Silversmith mine at Sandon is being doubled. To this end 35 men are engaged in dismantling the Silversmith mill and enlarging the Ivanhoe mill, acquired by the company recently. Much of the equipment of the Silversmith mill is being used in the reconstruction of the Ivanhoe. The Ivanhoe has a capacity

of 50 tons daily and the Silversmith 150 tons. When alterations have been completed the Ivanhoe will have a capacity of 150 to 300 tons. The Silversmith tramway will be used in transportation between the mine and mill, which are 4100 ft. apart. Ore-pockets are being built at the terminals. Mill construction was started in May of this year and will be completed in the fall, it is believed. The last work done in the mine disclosed ore to a depth of 120 ft. below the tenth level. A carload of ore accumulated in cleaning the old mill was shipped to the Bunker Hill smelter at Kellogg, Idaho.

Slocan.—Clarence Cunningham has been negotiating for property adjoining the Standard mine, and it is supposed that he is the purchaser of the Standard. He has been unusually successful in rehabilitating the mines in this district that were considered to be worked out.—The Great Northern Railway Co. has notified the people of Rossland that it intends to abandon the branch into that town. It has been an expensive line to maintain, and the deficit on the operating expenses for last year amounted to \$48,000.

Stewart.—The strike at the Premier mine has been settled, the men having agreed to accept the reduced wage-scale on the understanding that living conditions shall be improved at the camp. As there are some 2000 tons of ore sacked ready for shipment, which the company was unable to transport while the snow lasted, little or no work will be done in the mine for a time, but all energy will be centred on the completion of the mill and aerial tramway. At present about 200 men are employed, but probably this force will be doubled within the next month. Between five and six thousand tons of ore was sent to Tacoma last winter. The company refuses to give any information as to the tenor of this ore. The ore shipped in the winter of 1919-'20 ran 3.175 oz. in gold and 108 oz. in silver per ton, which at the present price of silver would give it a value of about \$125 per ton.—It is currently reported that the Guggenheims have bonded the Forty-nine group.—The United States stockholders in the Algonquin syndicate, most of the stock of which is held in Belgium, are endeavoring to persuade the Belgian shareholders to continue the work of developing the Spider group, which is believed to be a good property, and one that can soon be brought to a producing basis.

The McAllister mine, at Three Forks, will be re-opened on July 1. At the start work will be confined to development, there being no encouragement for the production of ore at the present time.

MEXICO

Durango.—Ore is being shipped from the old Promontorio mines, situated near Chinacates. These mines are owned by Maximiliano Dam of this city. They are among the oldest producing mines in Mexico. The present shipments are being made to the smelter of the American Smelting & Refining Co. at Chihuahua.—In the Tamazula district, W. C. Taylor is developing a group of gold claims which are yielding good quantities of high-grade ore.—The Santa Cruz Mining Co., an American concern, is shipping silver-lead ore from its mine, situated five days by mule-back from Papasquaro. S. W. Loving is manager.

El Tigre.—The regular dividend of 5c. per share and an extra dividend of 2c. have been declared by the Lucky Tiger-Combination Gold Mining Co., payable to stockholders of record on June 10. The company owns and operates the El Tigre silver mine.

Guanajuato.—A 500-hp. air-compressor for the Guanajuato Consolidated Mining & Milling Co. has just arrived, together with a number of machine-drills, a drill-sharpener, drill-steel, and other machinery. As soon as this compressor can be installed, the company expects to increase its development work to a great extent. Since the mill was shut-down in February about 750 ft. of development work per

month has been done; the results are proving satisfactory, especially in the lower levels. The company hopes to develop sufficient ore of milling grade to justify increasing the capacity of its mill from about 7000 tons per month up to 10,000 tons; by treating a larger tonnage it is expected to reduce the cost per ounce of silver. In addition to the development work in the mine extensive repairs have been made. The tracks, wiring, hoists, etc., have been repaired and put in first-class condition; many of the old timbers in the mines are being renewed.

Torreón.—Two more furnaces at the smelter of the Penoles Mining Co. at Torreón were recently blown-in, making six furnaces that are now in operation. Ore shipments are coming to the smelter slowly and they may not furnish sufficient ore to keep the plant in operation for a long period.

Zacatecas.—The Guarda group of gold-silver mines at La-Noria has been filed upon by Charles E. Snider, who plans to start work. Ore will be shipped to the smelter of the American Smelting & Refining Co. at Aguas Calientes, it is stated. In this district George H. Davis is developing the Purisima mine.—John O. Emerson has made application for title to 94 mining claims in the Miguel del Mesquital district. Included in this list of properties is the old Santa Catarina group which was abandoned several years ago.

ONTARIO

Porcupine.—At the annual meeting of the Dome Mines on June 14, H. P. De Pencier stated that since the issue of the annual report there had been a distinct improvement in the outlook, and production had exceeded his expectations. On the 10th level an ore-shoot 360 ft. in length had been developed and diamond-drilling 300 ft. below the 10th level gave promise of richer ore than had been so far recovered.

The Allied Porcupine, capitalized at \$5,000,000, which has acquired properties aggregating 720 acres, including the plant and mill of the Three Nations, having a daily capacity of 40 tons, had made plans for the continuance of lateral work on the 200-ft. level, including extensive cross-cutting to tap outcropping veins, and will also undertake diamond-drilling to test the vein system to a depth of 1000 ft. Cyaniding equipment will be added to the mill.—The E. J. Longyear interests are planning a diamond-drilling campaign on the sand plains lying west of the known gold-bearing area and in the line of the strike of the ore deposits. As the discovery of an extension of the Sudbury nickel deposits, representing many millions of dollars in value, was due to the drilling operations carried on by the Longyear interests, the undertaking excites much interest.

Skead Township.—An important find on the Skead Gold Mines property is reported in a pit sunk 6 ft. A channel-sample across 15 in. of the vein is stated to assay \$79 per ton.

Sudbury.—The British America Nickel Corporation has carried through its re-financing scheme and its capital now comprises \$600,000 first income bonds, \$18,000,000 second income bonds, and \$20,000,000 common stock. Edgar N. Rhodes has been appointed president and managing director. A Gronningsater, late chief consulting engineer, has been appointed technical director. The company will resume operations as soon as conditions are favorable.

Toronto.—The annual meeting of the Ontario Mining Association was held at Cobalt from June 16 to 18 with a large attendance. A resolution was adopted strongly urging the construction of the projected Northern Light railway opening up the mining areas east and west of Swastika. Officers were elected as follows: President, R. B. Watson, general manager for the Nipissing Mining Co.; first vice-president, C. V. Corliss; second vice-president, J. P. Watson.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Blamey Stevens is in New York.

Henry M. Payne, of New York, is on his way to Mexico.

Morton Webber is on his way from New York to Mexico.

William R. Wright has left Mexico for Surrey, England.

F. G. Cottrell sailed from New York for Europe on June 11.

Edwin Shapley, recently of Philadelphia, is at Redlands, California.

J. K. MacGowan, vice-president of the Braden Copper Co., is in Europe.

J. W. Hamilton has moved from Eaton, Indiana, to Haileybury, Ontario.

E. H. Sutter, of Minerals Separation, has been in New York recently.

F. W. Denton, of Cambridge, Massachusetts, is at Palmsdale, Michigan.

J. Morgan Clements is expected in New York on his return from China.

A. D. M. Rain, of the Braden Copper Co., Chile, was in New York recently.

Frank Scheuber has moved from Melrose, Oregon, to Livingston, Montana.

E. A. H. Tays has moved from Nogales, Arizona, to San Blas, Sinaloa, Mexico.

William L. Boos, of San Francisco, has gone to Cambridge, Massachusetts.

L. H. Goodwin, of New York, is in the Black Hills of South Dakota for two months.

S. T. McElroy has returned to Silverhorn, Washington, from Mt. Montgomery, Nevada.

H. C. Bellinger, vice-president of the Chile Copper Co., left Chuquicamata on June 10 for New York.

O. F. Brinton has been appointed consulting engineer to the Bingham-Galena Mining Co., at Bingham, Utah.

J. E. Bamberger, president of the Ontario Silver Mining Co. at Park City, Utah, is making a tour of Europe.

W. L. Whitehead, after an extensive tour throughout South America, has returned to Cambridge, Massachusetts.

F. G. Janney, general superintendent of mills for the Utah Copper Co., has returned to Garfield, Utah, after a month in the East.

F. G. Cottrell, chairman of the division of chemistry and chemical technology of the National Research Council, is in England.

John L. May, of Salt Lake City, has been appointed assayer in charge of the Salt Lake Assay Office. He took up his duties on July 1.

C. W. Newton, general manager and director of the Callahan Zinc Lead Co., of Wallace, Idaho, has gone to New York to attend the annual meeting.

Ross E. Mills has returned to his home in Salt Lake City, after spending two years in Ecuador as superintendent of a silver mine owned by New York capitalists.

Carl A. Wendell, of New York, has been appointed consulting engineer of the U. S. Bureau of Mines in matter relating to coal washing and coal preparation.

D. D. Moffat has returned to Salt Lake City after a trip to the Ray and Chino properties in Arizona and New Mexico, and to the Shasta zinc property in northern California.

Edwin T. Hodge, professor of ore deposits at the University of Oregon, will spend the early part of the summer in the examination of mining properties in British Columbia.

William Koerner, who has had charge of developing the Flin Flon mine in Manitoba, together with Richard N. Hunt

and R. J. Nesbit, mechanical superintendent at the Mayo Valley Mines smelter at Thompson, were at Silverhorn last week.

Robert G. Wilson, chief of the Tax Division of the American Mining Congress, has resigned to form a partnership with William Huff Wagner, valuation engineer of the Bureau of Internal Revenue. The firm will be known as Wilson & Wagner, consulting mining engineers, accountants and specialists in the taxation of the mineral industries, with offices in the Munsey building, Washington, D. C.

Frederick F. Sharpless was recently appointed Secretary of the Institute in succession to Bradley Stoughton, resigned.

Frederick F. Sharpless

Editorial comment, and a brief biography of the new secretary, will be found on page 1 of this issue.

Obituary

James H. Billingsley, president of the Frontier Mining Co., died at his home in Galena, Illinois, on June 16. He was one of the most prominent zinc-lead operators of the lead-zinc district of south-west Wisconsin. He came to Wisconsin in 1905, first developing the Frontier mine at Benton. In succession he developed and operated, with his associates, the Calvert mine, Hird mines No. 1, 2, and 3, the Bull Moose and Middle mines, and others. He was honored several times with election as mayor of the city of Galena, and was a director of the American Zinc Institute. He was well known for his kindly and generous treatment of those in his employ; at one time 700 men were carried on the payrolls of the Frontier Mining Company.

Book Reviews

American English. By Gilbert M. Tucker. Published by Alfred A. Knopf, New York. Price, \$5.

A frank discussion of the minor differences between the two great English-speaking nations is always interesting and instructive; the conclusion reached after reading Mr. Tucker's book on American English is that it is strange that so many obvious phases of the subject have escaped attention before. The book is written to disprove the contention of the large number of English writers of note that the pronunciation and spelling of English in America is incorrect and is degenerating. The author quotes from various sources to prove that this is the general impression in England—as it undoubtedly is; but for every Roland, Mr. Tucker produces an Oliver. The result is a collection of interesting extracts and comments.

As regards speech and pronunciation, the author makes an excellent point when he states that if the talk of street-loafers in American cities, and the verbal peculiarities that one may find in the outlying regions of Texas, are to be counted as characteristic of American speech, we must also take just as careful account of the lingo of the slums of London, and Cork, and of the jargon of the less progressive counties in the three kingdoms. To compare the conversation of a London drawing-room with the talk that one might hear in a road-house in Arkansas is manifestly unprofitable; nothing can be learned by such methods. Yet this is precisely what is done by the average Englishman who has never visited America. I remember taking a young friend, who had recently arrived from London, to a New York club for luncheon. After the meal we adjourned to the smoking-room, into which soon strolled a number of members of the club. The conversation of the group first to arrive was distinctly audible to us; one man's voice was above those of the others; my young friend leaned forward and enquired of me, "An Englishman?" I assured him that the gentleman in question had been born in America and had never been out of it. Later on, another group strolled near us, all of them talking the while in a perfectly natural manner. My young friend was now convinced. "Those are Englishmen, anyway", he asserted. "No," I was obliged to reply, "they are all 100% Americans." This explains to some extent the viewpoint taken by many Englishmen.

Another fact that the author emphasizes in his book is that America has no dialects. In England, as the Dean of Ely wrote in the 'Outlook', a west-country peasant cannot understand the artisan of Yorkshire. As proof of this diversity of language in the old country the author quotes the 250 odd glossaries of domestic dialects. A distinguished traveler, once chaplain to Queen Victoria, and one who knew the United States as few Englishmen know it, mentions as "a remarkable fact that the English spoken in America is not only very pure, but also is spoken with equal purity by all classes—spoken in San Francisco just as it is spoken in New York, on the Gulf of Mexico just as on the Great Lakes. There is nothing resembling this in Europe, where every country, as in England, has a different dialect. Often in parts of the country [United States] most remote from each other, in wooden shanties and in the poorest huts, I had this interesting fact of the purity and identity of the language of the Americans forced on my attention, and at such times I thought, not without shame and sorrow, of the wretched vocabulary, consisting of not more than three or four hundred words, and those most ungrammatically used, and always more or less mispronounced, of our peasantry". Who ever heard, asks the author of 'American English', an American gamín call paper 'piper' or lady 'lidy', or rain 'rine'; which reminds me of a story that I heard when I was

in Australia: a Sunday-school picnic was being held; a small boy wanted some grapes, but cake came first on the menu. "No", said the teacher, "you eat the 'kike' first; you'll have the 'gripes' afterwards." This is no exaggeration of cockney pronunciation. To be fair, the speech and average pronunciation of the whole of the people of the two countries must be compared; but no cultured Englishman would allow that the dialects of Yorkshire, of Devonshire, and of London are part and parcel of the Briton's pronunciation of English; yet they are, undoubtedly.

There is a paraphrased proverb to the effect that people who live in glass houses should pull down the blinds. The frequent contention of British critics that the language is being mutilated in the United States provokes a rejoinder; the author of this book gives chapter and verse; even the late King Edward's private secretary, (then) Sir Francis Knollys, was guilty of a painful exhibition of bad grammar in a letter written to Professor Rawson, of the Thirteen Club of New York, in 1896. Mr. Tucker criticizes the use of the plural after a negation—a usual British error. Ruskin said: "A daisy is common, and a baby not uncommon; neither are vulgar". The practice is deeply rooted. Even Galsworthy makes one of his heroines say, "Who in our world would marry me if they knew". Phrases like "these sort of people", so common, are also criticized. Anthony Trollope favors another anglicism when he says, "I have done more than slept on it; I have laid awake upon it".

As to variations in spelling on different sides of the Atlantic, the author goes to considerable pains to justify the standard adopted by American dictionaries and American literature. The British practice of writing 'programme' and not 'diagramme', 'honour' and 'honorary', 'armour' and 'armory' results in a jumble of confusion, he says. America has its slang, but so has Britain. The slang of America is usually humorous and incisive; it often gives a remarkable emphasis to what is said or written. British slang is neither humorous nor emphatic. Mr. Tucker quotes from a British novel in which a peer of the realm speaks of doing something "like those millionaires did"; he talks about a "piffing law"; characterizes an approaching wedding as "a beast of a nuisance"; offers to sing "the bally thing"; asks his wife at table, not to pass the jam, but to "shove it along"; tells her to "chuck him another match"; and remarks that something "bucks you up". I should say that the difference between the slangs of Britain and the United States is that here it is the work and thought of authors. I recently came across an acknowledgment by Sir Walter Raleigh, the professor of English literature in Oxford University, who said, in 1918: "For one thing, we on this side now borrow, and borrow very freely, the more picturesque colloquialisms of America. On informal occasions I sometimes brighten my own speech with phrases which I think I owe to one of the best of living American authors, Mr. George Ade, of Chicago, the author of 'Fables in Slang' ". English slang is not copied in America. The proof of the pudding is in the eating; the adoption of slang phrases and words is an evidence that they are part and parcel of our present-day literature. American slang adds to the gaiety of the nations; even Englishmen have an appreciation of its pungency. British slang, on the other hand, is neither witty nor apt.

A large portion of the book is taken up with a critical study of exotic and real Americanisms, with quotations from a number of treatises on the subject. One British critic, after reading in the Albany 'Journal' of a man who came in late one night after an unsuccessful attempt to open the front door with his umbrella, and found himself next morning, "overcoat, hat, jag and all, stretched out in the bathtub", defines 'jag' as "a slang term for an umbrella, possibly from that article being so constantly carried"! A large number of so-called Americanisms are found to be of British origin. 'Guess' was a favorite expression of Chaucer's; the

authors of 'King's English'—a stupid title, by the way—say that "we have it, not from Chaucer, but from the Yankees". Mr. Tucker remarks caustically that were these gentlemen to compile a glossary to Chaucer they would have an entry something like this: "Guess: Americanism for believe, think, fancy". Similarly, if it were a glossary to Shakespeare, there would be an item: "Baggage: Americanism for luggage". The author proves his point that the English language is not deteriorating in America. A large number of Englishmen of high standing have declared that the language spoken in America is, on the whole, purer than the English spoken in England. A critic, like the author of the 'Unspeakable Scot' and the 'Unbounding American', who admits that he has "never been to the United States", but who has the temerity to state that the Americans "having inherited, borrowed, or stolen a beautiful language, willfully and of set purpose degrade, distort, and misspell it" should be put in the class of irresponsible persons whose one object in life seems to be the fomenting of international friction. When the London bus-conductor speaks as do his passengers, then it will be realized why nearly all the people of the United States adopt a uniform language—why such a preponderating proportion use carefully enunciated words.—A. W. A.

Introduction to Qualitative Chemical Analysis. By H. Wilhelm Fresenius. 17th edition by C. Remigius Fresenius. Translated by G. Ainsworth Mitchell. 954 pp., 57 ill. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$8.

The seventeenth German edition of the standard work of Fresenius, which was first planned in 1840, has been remodeled to make it conform to the modern conceptions of chemistry. A chapter dealing with reagents, which appeared in former editions, has been omitted as being no longer necessary; the notes and additions to the systematic course have been transferred to a separate chapter. The principles of the analytical systems used in the course are made clearer by the addition of tables and general surveys of each stage. The contents of the book are as follows: Part I: General chemical principles and methods of analytical chemistry. Behavior of substances to reagents. Reactions of cations. Reactions of anions. Part II: Systematic course of qualitative chemical analysis. Practical methods of the general course. Practical methods for special cases. Explanatory notes and additions to the practical process. Appendix: Behavior of the most important alkaloids toward reagents, and systematic course for their identification. Remarks on the correct choice of exercises for practice. Tabulation of the results obtained with the substances analyzed for practice. Solubility tables. The translator, who is to be congratulated on having performed a prodigious task, is the editor of 'The Analyst' of London.

Metallography: Part II, The Metals and Common Alloys. By Samuel L. Hoyt. 462 pp., ill. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$5.

This book is the second volume of a three-book series of which the first volume, on principles, was published last year; the third volume, technical practice, is in preparation. It describes the more important metals and alloys, the description including the constitution and micro-structure, the physical and mechanical properties for different conditions of heat and mechanical treatment, the effects of impurities commonly present, and a brief discussion of the uses. Compositions of particular importance have been treated in detail, and measured values of the important properties have been given. Other features are critical-point diagrams, constitution diagrams, structural diagrams, and photomicrographs.

Antimony, cents per pound.....	6
Copper, electrolytic, cents per pound.....	13
Lead, pig, cents per pound.....	4.65
Platinum, pure, per ounce.....	\$75
Platinum, 10% iridium, per ounce.....	\$105
Quicksilver, per flask of 75 lb.....	\$48
Spelter, cents per pound.....	7.50
Zinc-dust, cents per pound.....	9.00—9.50

EASTERN METAL MARKET

(By wire from New York)

June 27.—Copper is inactive but easy. Lead is quiet and lower. Zinc is stagnant but easier.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

A FIVE BILLION DOLLAR BUDGET

Six months ago the Democratic Secretary of the Treasury was criticized for proposing a new budget of \$4,653,856,769. But on the basis of Secretary Mellon's latest estimates the budget for the new fiscal year will exceed the old administration's proposal by over \$400,000,000, according to 'The Index', published by the New York Trust Co. The new estimates disclose a rate of spending practically five times as great as the expenditure in 1914.

There may possibly be something to be said in extenuation of the large army and navy appropriations, while other costly legacies of the World War cannot yet be eliminated. But it would seem to be within the ability of an able administration to economize more effectively in an item of civil expenditure that is now running three times larger than in pre-war days.

Receipts and disbursements in the fiscal year 1914 compare as follows with Secretary Mellon's estimates for the new year, beginning July 1:

	1914	1922
Receipts		
Customs	\$292,320,000	\$300,000,000
Corporation excise	10,671,000
Individual and corp. income and profits taxes	60,709,000	2,350,000,000
Miscellaneous taxes	308,661,000	1,350,000,000
Sale public lands	2,571,000	1,500,000
Miscellaneous receipts	59,740,000	546,143,000*
Postal revenue	287,934,000	500,000,000†
Total receipts	\$1,022,006,000	\$5,047,043,000
Disbursements		
Civil and miscellaneous	\$304,180,000	\$1,201,628,000
War Department	173,522,000	509,750,000
Navy Department	139,682,000	515,225,000
Public debt interest	22,862,999	975,000,000
Postal expenditures	283,558,000	543,512,000
Shipping Board	124,200,000
Panama Canal	34,820,000	10,000,000
Debt redemption	109,000	421,354,000
Bank note cancellation	6,949,000	130,000,000
Railroads	545,206,000
Total disbursements	\$1,025,691,000	\$5,005,875,000
Total receipts	1,022,604,000	5,047,043,000
Deficit	\$3,088,000†	\$18,232,000

*Includes \$255,020,000 anticipated interest on foreign obligations held by the United States Treasury.

†Arbitrary estimate, the same amount being added to the net estimated deficit to arrive at total disbursement.

†In 1914 the sale of \$3,118,000 bonds not included in receipt above left and actual surplus of \$28,000,000.

MONEY AND EXCHANGE

Foreign quotations on June 28 are as follows:

Sterling, dollars: Cable	3.77 1/4
" Demand	3.78
Francs, cents: Cable	8.12
" Demand	8.14
Lire, cents: Demand	4.98
Marks, cents	1.42

Eastern Metal Market

New York, June 22.

Improvement of any consequence is difficult to find in any of the markets and prices in some are lower.

Buying of copper is no better and the little business going is being taken at concessions.

The tin market is quiet and fairly steady.

There is little demand for lead and prices are lower.

The zinc market is stagnant as to buying but steady as to prices.

Antimony is a little softer.

IRON AND STEEL

In many lines of steel consumption business seems to have adjourned for the summer, but meanwhile liquidation of steel products in the hands of users is proceeding in a most unusual way. Practically all large manufacturing consumers have turned jobbers and are selling bars, plates, structural shapes, or whatever they have on hand, at prices close to the warehouse basis, says 'The Iron Age'. Thus while the mills are being called on for less steel than at any time this year, the process of 'cleaning-up' all accumulated rolled products is going on, against a day when the country will be more nearly bare of steel than in many years.

The operation of blast-furnaces and steel works is slightly below the rate of last week. In the past two months the Steel Corporation's ingot production seems to have fallen off more relatively than that of the leading independent companies. The Carnegie Steel Co. has blown-out another blast-furnace and now has only 14 in operation out of 59.

There is no longer any strict adherence to the prices announced by the Steel Corporation as effective April 13. Reports have gone through the trade that a formal announcement of lower prices would be made July 1. However, market developments appear to be making any such formality unnecessary. All producers are meeting competition as it develops.

COPPER

Sentiment in this market varies according to the interest interviewed. In some quarters, gloom is apparent while in others a fair business is reported, but in much reduced volume as compared with May. One interest reports continued orders in moderate volume from Germany, France, and some other countries, but almost none from Great Britain, due to the coal strike. Domestic buying is flat though reports from some sections early this week were to the effect that manufacturers using copper were fairly busy. Most of the large producers of electrolytic copper do not quote June-July delivery under 13.25c., delivered, with some as high as 13.50c., but there are a few sellers who are taking the business offered at as low as 13c., delivered, or 12.75c., New York. Reports of sales of small lots at 12.75c., delivered, or 12.50c., New York, are not confirmed. Lake copper is quoted about the same as electrolytic, depending on the seller.

TIN

The week for the most part has been a quiet one with trading between dealers light and with consumers doing very little buying. One June 15 it is estimated that about 200 tons of future shipment metal was sold at around 30c. The course of the market has been but little changed from that prevailing for some weeks—those wanting to buy have had difficulty in securing the metal at the time and when sellers have been ready to do business there have been few buyers. Spot Straits, New York, has hovered around 29 to 30c. during the past week with the quotation yesterday at 28.75c. The London market has declined during the week

with quotations yesterday about £3 per ton below those a week ago, spot standard being quoted at £164 10s., future standard at £167 5s., and spot Straits at £165 5s. Arrivals thus far this month have been 930 tons with 2000 tons reported aloft.

LEAD

Stagnation is reported with no business and no inquiries reported either by big or little producers and sellers. The leading interest continues its quotation at 4.50c., New York and St. Louis, but in the outside market it is possible to buy without difficulty at 4.20 to 4.25c., St. Louis, or 4.40 to 4.45c., New York. One seller reports that the trade feels that lead will not go lower unless foreign conditions force the market down. American conditions do not warrant a decline. Production is not large and stocks are light with the statistical position the strongest of any of the metals.

ZINC

This market is also stagnant and has been for some weeks, but it is steadier than the lead market as to prices. The bottom for some time has been 4.45c., St. Louis, or 4.95c., New York, for prime Western for early delivery, but sales have been few and confined to small lots for prompt delivery and to only a few producers as sellers. Offerings to buy at 4.40c., St. Louis, are reported as fairly numerous, but there are practically no sellers at this level. It is possible that 4.45c., St. Louis, is also the bottom of the zinc market.

ANTIMONY

The market is quiet and easier at 5.12½c., New York, duty paid, for wholesale lots for early delivery, with the probability that 5c. could be done under favorable circumstances.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, for early delivery are quoted by the leading producer unchanged at 28c. f.o.b. plant, while the same grade from other sellers is obtainable at 22.50 to 23.50c., New York.

ORES

Tungsten: There is no interest on the part of consumers and the market is quiet and nominally unchanged at \$3.25 per unit for Chinese ore and \$4 per unit for Bolivian and other high-grade ores.

Ferro-tungsten is unchanged at 48 to 58c. per pound of contained tungsten in lump form, guaranteed as to quality. Other grades are lower.

Molybdenum: Conditions are unchanged and the market is nominal at 50c. per pound of MoS₂ in regular concentrate.

Manganese: There is no demand. Quotations are nominal at 22.50c. per unit, seaboard, with the probability that this can be shaded. Imports continue heavy at over 54,000 tons for May or over 60,000 tons per month for the 11 months ended with May.

Manganese-Iron Alloys: Absolute stagnation features the demand for ferro-manganese and spiegeleisen. Prices for the former are nominal at \$75 per ton, Atlantic seaboard, for the British alloy, with the American obtained at \$80, seaboard, from first hands and perhaps lower for re-sale alloys. Spiegeleisen is nominal at \$30 to \$32, furnace.

Of 40,256,030 lb. of refined copper exported during April, 999,358 lb. went to Belgium, 10,800,273 to France, 15,837,896 to Germany, 223,915 to Italy, 1,166,600 to the Netherlands, 7,976,634 to the United Kingdom, 1,541,713 to Canada, and 1,709,641 to other countries.

Current Prices of Commodities

The figures given on this page represent the regular current price, at the time of our going to press, to industrial buyers of standard commodities in small wholesale lots on San Francisco Bay. They should not be construed as being quotations nor as being either the lowest or the highest price; they are given rather as a guide by which to follow the trend of the market or to estimate the approximate cost of materials and supplies.

PORTLAND CEMENT, LIME, ETC.

Fire-brick, clay, per 1000, in carload lots.	60.70
Fire-clay, in bags, per ton.	18.00
Lime, lump, in barrels, per barrel of 180 lb.	3.25
Portland cement, in bags, per barrel of 380 lb.	4.20
Allowance of 15c. for bags returned in good condition.	
Portland cement, in barrels, per barrel of 400 lb.	5.50
A deduction of 50c. per barrel is made on lime and cement when sold in carload lots.	

ORES AND MINERALS

The following prices represent approximately what can be obtained for the products indicated delivered at points on San Francisco Bay. These, of course, vary widely with the grade and purity of the ores. The present stagnant condition of the market makes many of the quotations purely nominal; most of the ores can be purchased at these prices, but it should be understood that it is not easy for the producer to market them at this time.

Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per %.	60c.
Asbestos (crysotile), according to length of fibre, per ton.	\$20 to \$2500
Barite, white and free of iron (crude), per ton.	5 to 10
Bismuth ore, not less than 20% Bi, per % Bi.	12
Feldspar, crude, lump, free of iron, per ton.	5 to 10
Fluorspar, 85% calcium fluoride, per ton.	15 to 20
Fuller's earth, ground to pass 80-mesh, per ton.	5 to 10
Graphite, crystalline, per pound.	3c. to 7c.
Magnetite, calcined, per ton.	25 to 35
Manganese ore, less than 0.75% Fe; less than 6% SiO ₂ , per ton	25 to 30
Mica, according to size, cleanness, and cleavage, per pound.	1 to 8
Molybdenite, not less than 85%, free of copper, per % MoS ₂ .	8 to 12
Orchre, according to strength, crude, per ton.	8 to 15
Sulphur, 99.5% pure, only trace of As and Se, per ton.	15 to 18
Talc, lump, white, per ton.	7.50 to 10
Tin ore, not less than 60% Sn, per % Sn.	5
Tungsten ore, not less than 65% WO ₃ , per % WO ₃ .	2.75 to 3.00

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE CAPACITY OF MARCY BALL-MILLS

On the front cover of the 'Mining and Scientific Press' of June 4, 1921, there appears an advertisement for the Mine & Smelter Supply Co., in which is an illustration of 18 Marcy ball-mills installed in the concentrator at Braden, Chile. The statement is made that "Eighteen Marcy ball-mills in this installation are crushing about 600 tons per 24 hours for table concentration. The feed is 30% plus one inch". No well informed metallurgist could possibly misinterpret this statement; the excellent performance of the Marcy mill is too generally known to permit misunderstanding. Obviously, however, the statement would be more precise if the word 'each' were inserted after "are" so as to read "... are each crushing about 600 tons per 24 hours ...".

THE SULLIVAN 'TURBINAIR' HOIST

The Sullivan 'Turbinair' hoist meets the demand for a small, compact, but powerful, portable hoisting engine, for use in mines, quarries, yards, and shops. The 'Turbinair' hoist may be mounted on a cross-bar or column in a shaft, winze, or raise, for handling drills, steel, or timbers; it may be bolted to a timber or girder or to a wall or floor, for pulling cars, piling lumber, and any odd jobs of hoisting or hauling. Its capacity is from 1500 to 2000 lb. dead load lifted vertically at 100 ft. per minute, under an air-pressure varying from 50 to 75 lb. The 'Turbinair' hoist weighs 285 lb. and its drum will accommodate a maximum of 500 ft. of $\frac{5}{8}$ -in. wire rope. Mine superintendents, foremen, and miners have expressed their surprise and satisfaction at the ease of operation and control of the 'Turbinair' hoist, and at its great pulling power.

The machine is novel in design, but exceedingly simple in construction. It consists of a cylindrical drum, mounted on a steel frame that completely encloses the operating mechanism. This comprises a Sullivan 'Turbinair' motor, and reduction gearing, which drives the drum-shell. The motor is a copy in miniature of the 'Turbinair' motor used with such success for several years past in driving Sullivan compressed-air 'Ironclad' coal-cutters. The two cylindrical rotors are provided with right- and left-hand helical flutes or vanes converging to a spur tooth in the centre. The two rotors mesh together as they revolve under the influence of the incoming air. This motor develops a high starting torque, is economical of power, as it uses the air expansively, and has shown long life and sustained efficiency. 'Turbinair' coal-cutters are in use which have required no repairs in a period of five years.

The hoist is provided with a friction-clutch and brake. When both of these are released the rope may be pulled freely from the drum. The friction-clutch may be locked in position and the load raised or lowered, controlled entirely by the throttle-valve. The brake is of the band type and is of sufficient strength to hold any load within the capacity of the hoist. It works smoothly, thus putting no unnecessary stress on mechanism or rope.

The air is admitted at the axis of the drum through a

hollow shaft, and the motor revolves with the drum. Ball bearings are employed, and all mechanism is totally enclosed and well lubricated. The rotors are lubricated by an automatic oiler. The hoist is quiet in operation, an important

Sullivan 'Turbinair' Hoist Set for Hauling an Ore-Scraper

One of the Two Rotors Used in the 'Turbinair' Hoist-Motor

factor when signals and instructions are being transmitted. The Sullivan company feels entire confidence in recommending the 'Turbinair' hoist for any duty for which portable-

column air-hoists have been used in the past; with increased factors of operating convenience, economy, and power.

Details of 'Turbinaire' Hoists

Capacity at 80-lb. air-pressure (vertical lift), lb. 1500-2000	
Speed at maximum load, ft. per minute.....	100
Weight (net, less rope), lb.....	285
Horse-power	4½-6½
Overall length, in.....	22
Overall width, in.....	13½
Overall height, in.....	15½
Drum, diameter, in.....	9½
Drum, length, in.....	9½
Capacity of drum, ft. ½-in. wire rope.....	500
For column, diam., in.....	4½
Hose or pipe connection, in.....	¾

Equipment included: two column-clamps, one automatic oiler, one throttle-valve, four hose-clamp bolts with nuts and washers, three wrenches, and one oil-can.

TRANSPORTATION IN ALASKA

By E. M. Lagron

Freight-rates which have been absolutely prohibitive in interior Alaska will soon be reduced from \$350 per ton to approximately \$25. This will result in a flat saving of \$325 over the prevailing prices. It is a direct result of the advance of the new government railroad. The new rate will be effective, it is believed, with the completion of the railroad which extends from the tide-water to the interior.

Increased activities will result and mining machinery can soon be shipped to Fairbanks, Nenana, Fort Gibbon, Ruby, and other interior points. At present most of the freight to these places is sent by dog teams or 'mush' over the trails from the seaport towns of Valdez and Cordova.

One of the most marked improvements in transportation will be found in the big powerful 'caterpillar' train which operates on a 60-mile haul. These tractors are manufactured by the Holt Manufacturing Co., and are the same as those supplied the allied governments during the War. They carry about 50 tons of perishable foodstuffs and supplies over the snow and ice. Government engineers have been astonished at the remarkable ability of these tractors to operate at times with the thermometer at 40° below zero.

The recently perfected radiator frost-pad which protects the motor of the tractor, enables the outfit to operate regardless of weather conditions. Another engineering asset of this particular machine will be found in the articulated roller-frame and the equalizer-bar which join the two portions of the tractor-truck and supporting-roller. This latter factor enables the tractor to conform to the unevenness of the ground and to climb over obstacles and yet assures perfect traction without slipping. It is one of the refinements and modifications made possible by war experience.

GIANT NON-FREEZING POWDER

Once every few years one or another of the leading powder companies puts on the market an explosive that is slightly different from the other kinds previously produced. The differences are usually manifested in a small change in one or more of the properties of the explosive. There has been a recent production, however, of a new explosive which is fundamentally different from other dynamites on the market. A new formula and different ingredients are used in its composition. In addition to its non-freezing properties the explosive has another important feature which makes it of especial value to blasters. Other dynamites cause violent throbbing headaches to the persons who use and handle it. This so called 'powder headache' could never be avoided and was always the dread of blasters. Reports

have been received stating that the cartridges of the new explosive were handled and loaded without gloves and not the slightest headache was experienced.

COMMERCIAL PARAGRAPHS

The Dayton-Dowd Co., of Quincy, Illinois, has issued Bulletin No. 244 on type CS single-stage centrifugal pumps. It is now ready for distribution.

The Coast Equipment Co., of San Francisco, has recently been incorporated with the following directors: H. S. Tittle, Robert Dalziel Jr., L. A. Somers, Thomas Harris, and Alfred H. Potbury. L. A. Somers is general manager and Alfred H. Potbury, engineer. The company has offices in San Francisco, Los Angeles, Portland, and Seattle, and represents a number of well-known manufacturers of steam and electric equipment on the Pacific Coast.

An interesting booklet is 'Shaft Sinking', recently issued by the E. J. Longyear Co., of Minneapolis, as Bulletin No. 15. The mining department of the Longyear company maintains an experienced organization capable of handling development problems, whether these be of shaft-sinking, drifting, tunneling, excavating stations and loading-pockets, concreting shafts and workings, or repairing and altering existing shafts or mine openings. Among the undertakings described briefly are the shafts at the Flin Flon mine in Manitoba; the Castleton shaft of the Staso Milling Co. at Poultney, Vermont; the Ankerite shaft, sunk for the Coniagas company at Porcupine; the Wallenberg shaft in Norway; and the Pyne shaft, for the Woodward Iron Co. at Bessemer, Alabama.

The application of the Curtis steam-turbine for driving circulating and boiler-feed pumps and other apparatus has been successfully developed by the General Electric Co. The turbine may be designed for either condensing or non-condensing operation. It may be adapted for any steam pressure from 60 to 250 lb., for either dry or super-heated steam, and for speeds from 1200 to 5000 r.p.m. It may be arranged with either one, two, or three stages, depending upon operating conditions. According to Bulletin No. 42,019, just issued, this turbine represents the best type of design and construction, based on practical experience gained in building Curtis steam-turbines. Every detail has been worked out so as to make all parts as simple as possible and of ample size and strength. A description of the principle involved in this turbine, and a careful summary of its several parts, including wheel, shaft, and buckets, wheel-casing, bearings, packing, governor, governor valve, emergency governor, and other elements, is included.

The first public demonstration of the gas-mask, for protection against carbon monoxide, manufactured by the Mine Safety Appliances Co., and in which is utilized the special chemical mixture called 'hopcalite', developed by the U. S. Bureau of Mines and Chemical Warfare Service, U. S. Army, was given the afternoon of May 26 in the special smoke room of the Bureau at Pittsburgh. In this test two men entered the smoke-room which contained 1% of carbon monoxide gas in the air. One of the men carried a canary bird into the room to indicate to the observers the poisonous nature of the atmosphere. The canary collapsed in 45 seconds, and was immediately removed to fresh air where it was revived with oxygen. While the gas-mask used will give protection in higher percentages of carbon monoxide, 1% of carbon monoxide in the air will kill a man in a few minutes time. The percentage found in working places where there is ventilation usually amounts to considerably less than 1%. One tenth of 1% of carbon monoxide, however, will seriously affect a man who is working and therefore breathing hard in about one-half hour's time, while two-tenths will affect him seriously in about 10 minutes.

T. A. RICKARD. . . . Editor

HOW the world's business is interlocked is suggested by the fact, among others, that the export trade in copper fluctuates with foreign exchange. When the dollar is at an excessive premium, our foreign customers cannot afford to buy our copper.

EFFORTS to end the flotation tangle by the purchase of the Minerals Separation company's numerous American patents have failed, owing to a wide difference between the price demanded and that which the leading copper operators were willing to pay.

THE War taught us to think in billions of dollars, but Russia is inaugurating a new era in finance. In that distressful country ruble notes are now being issued by the trillion. For the first four and a half months of the present year the amount aggregated 1,168,000,000,000 rubles, as against 225,000,000,000 for the same period last year.

ON another page we publish a short article on 'Conditions in Europe' as seen by Mr. Lewis W. Douglas, who has returned recently from the other side. It is a pleasure to publish this article, because, among other reasons, the author of it is the son of Mr. James S. Douglas and the grandson of James Douglas. Evidently the tradition of good citizenship is being maintained.

TIN from the Far East is sent to Pittsburgh, and then comes back to California, as tin-plate, for use in the canning of our domestic products. The Yukon company has evolved an ambitious scheme for the development of immense tin properties in the Federated Malay States; just now the company is the mainstay of the industry in that part of the world. If the tin could be smelted in California and the plate fabricated near-by, the cost of containers could be reduced considerably.

PROSPECTING by aeroplane would appear to be considered a rapid and healthful method of searching for oil in tropic countries. We learn that a company has acquired concessions from the government of Venezuela that will permit it to prospect the unexplored region in the delta of the Orinoco. The district is rugged and the vegetation is dense, so that ordinary prospecting would be dangerous and expensive. Lack of vegetation

will be taken as an index to the presence of oil, so that landing will be unnecessary for the preliminary reconnaissance. Sea-planes will be used.

SILVER producers in Mexico appreciate the attitude of the government of that country with regard to the reduction of taxes on metals exported. Below 60 cents per ounce there is no tax; when the market price rises above that amount, a graduated levy is made, which is of reasonable proportions, as compared with previous demands. One American company that operates in the State of Sonora reports a saving of about \$9000 per month on this account.

SENATOR KING, of Utah, has introduced a bill amending the Revenue Act so as to exempt gold-mining companies from the payment of the tax on their net income. This seems to us a reasonable thing to do, considering the hardships under which the gold-mining industry suffered during the War, when other branches of the mining industry prospered exceedingly. If gold mining is to be helped, the remission of the tax on income seems fair enough.

THE discontinuance of the practice of publishing, in the monthly bulletin, a condensed statement of the education and professional experience of intending members of the Institute, has deprived the profession of a source of biographical information; it is now no easy matter to obtain quickly any information as to the professional standing or activities of our confreres; but we are glad to see that the John W. Leonard Corporation, of Brooklyn, New York, has taken the initiative, and that a 'Who's Who in Engineering', containing about 10,000 records, will be published early in September. Engineers are timid of publicity; but it is time to realize that this attitude does not inspire public confidence. The new book, provided the members of the engineering professions agree to co-operate by sending in their records, should prove useful and interesting.

OPINIONS differ in regard to the pronunciation of some words. Mr. Ellwood Hendrick, in a review of a recent book on chemistry, regrets that the author did not enlighten him as to the correct pronunciation of the word 'pyrites'. Chemists make the word sound like

'pight-ease', he says; metallurgists in increasing numbers refer to the mineral in words that are reminiscent of 'pie-rights'. Our solution of the problem would be to discountenance the orgy of unnecessary pluralization that too often disfigures technical literature. In the book that Mr. Hendrick reviews we read that, "When native sulfur or metallic sulfide ores (pyrites) are roasted, they burn to the lower oxide of sulfur (SO_2)". Reduced to simple language, and aided by the use of customary spelling, this means that, when native sulphur or metallic sulphide ore (pyrite) is roasted in the air, it burns to the lower oxide of sulphur. The avoidance of the plural will solve the problem of pronunciation.

TWO factors may be cited to account for the large increase (\$40,000,000) in savings-bank deposits in New York during the first three months of the year—during a period of so-called industrial depression. They are the economic effects of prohibition, and the tendency of so many of the people to wait for the time when the dollar will have regained most of its pre-war value as a purchasing token, so that they may be able to buy as they did before the retailer named his own price and virtually told his customers to "take it or leave it". Several mining companies are keeping intact their balances of ore-reserves, and even adding to them, because metal prices are so low that unprofitable operation would result from the maintenance of the normal output. If the nation's reserves of capital and ore are to be taken as evidence, then we are undoubtedly in a more prosperous condition than is generally admitted, for 'prosperity' is not synonymous with 'spending'. When a readjustment of prices occurs, this real prosperity will be felt by all classes of the community.

INDIA'S influence on the market for gold and silver is not always realized; but, as Samuel Montagu & Company point out, a country with a population of over three hundred million persons with the hoarding instinct is likely to affect prices to a considerable degree. The last census of India revealed a reduction in the rate at which the population had been increasing. In the first decade of the century the gain was 7.1%, and in the second, only 1.2%, an increase of less than half that of the last decade of the 19th century, when the country was visited by two great famines. The influenza epidemic, which took a toll of 6,000,000 lives, left many in an enfeebled physical condition. This will account, to some extent, for the lessened ratio of increase in population during recent years. However, the financial gain, arising from the fact that Indian commodities were being exported at higher prices during and immediately following the Great War, more than offset the lessened increase of earning capacity, due to decreased numbers. For the fiscal year 1913-1914, there was a balance of trade against India amounting to 1202 laes of rupees; for the period 1919-1920 the balance was in favor of the country, and to the amount of 9533 laes. This remarkable reversal of economic conditions, taken in conjunc-

tion with the idiosyncracies of the Oriental in the matter of choice of gold or silver for a reserve fund, indicates how it is that India exercises such an important influence on the bullion markets of the world.

STOCKS of crude petroleum in the United States on May 31 were 155,341,000 barrels, equivalent to 115 days supply at the current rate of consumption. This breaks all existing records. Likewise the total domestic production for May, 41,920,000 barrels, exceeds that of any previous month, although the value of the oil at the wells was only 66 million dollars as compared with 113 million dollars for the 36,503,000 barrels produced during May 1920. This reflects the precipitous decline in the price of crude oil since the first of the year. Imports from Mexico have continued in large volume, despite the prevailing high export-duty that is now the subject of diplomatic discussion between our Government and that of Mexico. The monthly imports from Mexico up to June 1 averaged 11,000,000 barrels, or at almost double the rate of the corresponding period of last year. Oil production cannot be curtailed suddenly, and the only remedy for overflowing tanks and pipe-lines is to stimulate sales; this has been done by cutting the price of crude oil. On June 15 the Prairie Oil & Gas Company, the chief buying agency for the Standard Oil Company, reduced its price for mid-continental light oil to \$1 per barrel; in consequence, production will probably diminish for some time; then, as the stocks decline, higher prices will be restored. The fluctuations give a nice exhibition of the operation of the law of supply and demand, and at the same time emphasize the mistake made by the oil companies in not announcing reductions three months ago; as they now appear to realize, such action would have been profitable in the long run. The return of general prosperity would be hastened if a similar action were taken by those in control of other industries.

COMMERCIAL prosperity in any civilized country depends in large part upon the adjustment of its foreign trade relations. This point is emphasized by the Chamber of Commerce of the United States, which has sent its delegates to the International Chamber of Commerce, meeting in London at this time. The chairman of the American National Committee is Mr. A. C. Bedford, chairman of the Standard Oil Company and American vice-president of the International Chamber of Commerce. The head of the Standard Oil Company must be a man of very unusual parts, for no organization anywhere shows such a spirit of loyalty and efficiency as that of the Standard Oil; it is one of the few super-enterprises that seems to have found men of a character and capacity equal to the responsibilities entailed in the conduct of a worldwide business. The report of Mr. Bedford and his committee recognizes the fact that the United States, having become the principal creditor nation, must be prepared to extend credits on a large scale unless she is willing to face a great decrease of her export trade. Moreover, having changed her status from

a debtor to a creditor nation, she must be prepared to receive imports in larger volume than formerly, "and such an increase may react unfavorably on certain lines of trade". In short, "this problem of the readjustment of foreign trade relations is one of the most important developments that have resulted from the world war". When one reads the opinions of such men as these, and then notes the proceedings of Congress, which is busy gathering stones for a wall of tariffs, one is moved to sardonic laughter.

AGE has not dulled the truth of the old proverb that a man is judged by the company he keeps. We commend it to the gentlemen who are in control of the Bingham-Galena Mining Company; we might add that the prudent investor generally appraises a mining enterprise by the character of the men who are promoting it. Apparently Mr. Harry S. Joseph and his associates in the newly formed Bingham-Galena company, a consolidation of sundry properties at Bingham, Utah, are not particularly concerned with what people think of them, if one may judge from the fact that they have recently taken into partnership the notorious George Graham Rice, an individual to whom our readers neither need, nor probably desire, any introduction. Rice has recently underwritten 467,100 shares of Bingham-Galena stock, notwithstanding a vigorous protest from various reputable investment brokers and representatives of the Utah Chapter of the American Mining Congress at a public hearing before the State Securities Commission. Objection was based solely on the ground of Rice's bad reputation; it was argued that the good repute of the mining industry of Utah would suffer by reason of having his name associated with the enterprise. However, the Commission declined to interfere with the proposed transaction. In the light of the few facts at hand we are inclined to agree that the alternative decision would hardly have been justified; the circumstance that seems strange to us is the persistence of Mr. Joseph and his associates in consummating the deal with Rice in the face of strong opposition. The insistence of the owners seems foolish, especially if their mines are good ones, for they are giving their undertaking a black eye at the start. Well-informed speculators will suspect that the actual value of the mines is slight; there remain the ignorant and greedy, whose hard-earned money supports Rice and his followers. The properties may have merit and the enterprise may become profitable, but, just now, the finger of suspicion points to the contrary.

HOLDERS of stocks and bonds, in times of industrial depression as well as in times of hectic boom, are liable to appraise the value of their securities entirely on the basis of income and selling worth. Mr. R. H. Tingley, in a recent issue of the 'Annalist' gives publicity to the suggestion that money-worth should also be taken into consideration. In other words, the current value of the security, to a greater extent than is realized, lies in the purchasing power of the money that may be received

when it is sold. The sponsor of this novel method of appraisal quotes the American Smelting & Refining Company's securities for the purpose of comparison. Between the spring of 1920 and the month of May 1921, the money value of the stock decreased 22%, and that of the bonds, 11%. By considering the fall in the whole-sale prices of commodities during that period, the money-market value of the securities and their purchasing value on this basis, it is estimated that, if sugar were to be bought, the preferred stock has appreciated 134%, and the bonds, 165%; if wheat were to be bought, the preferred stock and bonds have increased in value 73% and 95%, respectively. Between May 23, 1920, and the same date of this year, commodity prices declined 36%. Bond prices advanced, according to Dun's index, by 6%; stocks, on the other hand, declined 12%. By selling a \$1000 American Smelting & Refining bond last year one could have bought, with the proceeds, 512 bushels of corn; this year the same transaction would result in the acquisition of 1382 bushels. Stocks and bonds, according to this method of appraisal, are cheap at present prices. The discussion raises the question as to whether stocks will appreciate in price in proportion to a further fall in commodity prices, or is the connection between the two so unstable that a rise or fall in the price of both, at one and the same time, is possible?

COLD-water thawing of frozen ground, preliminary to dredging, is being applied successfully in the vicinity of Fairbanks, according to the report of the Territorial Mine Inspector, Mr. B. D. Stewart. The overburden, at the place where the dredges are operating, averages about 26 feet in depth—about 14 feet of comparatively fine frozen gravel that is overlain with about 12 or 13 feet of 'muck'. The thawing apparatus consists of a manifold of 6-inch steel riveted pipe, and eight outlets to the 'points', which are 26 feet long, and of 4-inch pipe, not constricted at the ends, but discharging full bore. The points are set at 5-foot intervals, and settle, by their own weight, the full depth of 26 feet as the thawing proceeds. Three manifolds were employed this year on Fairbanks creek; and it is reported that the thawing has been accomplished with but a fraction of the expense involved in the use of steam-points. The results compare favorably with steam so far as time is concerned, and surpass it in the thoroughness with which the frost is overcome. In one case, two contiguous blocks of ground were being thawed, one with steam and one with water, the spacing between the blocks being the same in both cases. It was found that between each two steam-points a rib or comb of unthawed ground remained, whereas the block on which cold water had been used was uniformly and completely thawed throughout. The principal essential for the thawing of ground with cold water is an adequate supply of water at a temperature sufficiently above the freezing-point to ensure the melting of the ice. It is also necessary that the ground shall be as free as possible from large boulders, so that the 'points' can settle readily; they are not driven

into the ground. The working temperature of the water used should be about 40 F.; only a slight pressure is necessary. The work is being carried out on the property of the Fairbanks Dredging Company, where two dredges, one of which, made by the Union Construction Company, of San Francisco, has a capacity of 2500 cubic yards of gravel per day. Thus the cold-water thawing process is being proved on a working scale.

The Comstock Meeting

On June 27 and 28 the San Francisco Section of the Institute held a field meeting with the California Dredge Operators at Virginia City, Nevada. The two subjects of immediate interest were the revival of mining on Gold Hill and the dredging in Gold Cañon, both enterprises being conducted by corporations subsidiary to the Metals Exploration Company, which is identified with Mr. Bulkeley Wells and his friends of New York and Boston. An evening session, held at Minden, was devoted largely to papers covering these operations. Mr. George J. Young, Western editor of the 'Engineering and Mining Journal', gave a timely and interesting description of 'Mine Development at Gold Hill', and Mr. Gerald H. Hutton another on 'Dredge Mining Practice'. Sixty assembled at the dinner that preceded this meeting. Mr. Edwin Higgins, vice-chairman of the Section, was in the chair. Mr. Albert Burch read a letter from the president of the Institute, Mr. Edwin Ludlow, in reply to sundry criticisms from the local section, more particularly in regard to the continued publication of the Institute magazine. It was stated that members living in the larger cities did not desire the magazine, but that those stationed in places where news is not so plentiful liked to receive a publication so gratuitous. The local committee on Institute affairs, consisting of Messrs. Burch, Abbot A. Hanks, and Wilbur H. Grant, was requested to consider and report upon the President's communication. Mr. P. W. Bradley and Governor Boyle of Nevada led the discussion on Mr. Young's paper, which gave, in lucid outline, the plan of operations adopted by the United Comstock Mines—the company that is re-opening the Yellow Jacket, Belcher, Crown Point, and other famous mines, covering a length of 7000 feet along the Comstock lode. A new adit is being driven from American Flat to tap the old workings at a depth of 650 feet below the outcrop, in order to reach the lode-matter that was used to fill the old stopes and the ground that the former workers found too poor for exploitation. It is estimated by the engineers of the United Comstock Mines that 3,000,000 tons of \$6 material is assured. Of this assay-value, one third is gold at \$20 and two-thirds silver at \$1 per ounce. It is anticipated that the working cost can be kept down to \$3 per ton. Cyanidation, with concentration and separate treatment of the sulphides, will be used for extracting the precious metals. Successful leaching on the Comstock in the past has suffered from the presence of woody fibre and other carbonaceous matter present in the filling and tailing left from former

operations, but this obstacle, we are informed, has been overcome entirely in the experimental work done by Mr. C. J. Reid, who is metallurgist to the United Comstock Mines. As to the mining, it is proposed to use finger-raises to tap the old filling, and to supplement this method by top-slicing where necessary. Undoubtedly this is the most interesting technical feature of the enterprise. The old filling has consolidated sufficiently in places to call for the use of explosives; in other places, however, it is loose enough to require cribbing. What the pressure of settling ground can do in a mine is suggested by the fact that a layer of filling 7 feet thick can be squeezed into a layer 2½ feet thick; timbers 10 inches thick can be compressed to 3 inches. The physical condition of the ground in the old workings, whether filling or untouched lode-matter, varies so widely that no fixed system of mining can be applied uniformly. As to the metal contents, these also vary greatly; the existence of blocks of barren ground, of varying shape, will render difficult any scheme of systematic stoping. All this, of course, is perfectly well known to the engineers in charge of the work, and they are prepared to face these minor troubles in due course. The old filling is difficult to sample; so also is the virgin ground that has been shattered unequally by natural pressure; nevertheless, the results of the sampling are believed to have been adequately checked by comparing moil-samples with car-samples, and these in turn with mill-runs. It will occur to the reader that, in such a locality and in such a lode, there are chances of finding pockets of rich ore that were missed by the old-timers. Such chances, presumably, are slim, because the upper horizons have been well explored, not only by cross-cuts but by diamond-drilling. The engineers in charge do not anticipate the discovery of bonanzas within the scope of their venture, but they are confident of the trustworthiness of their sampling and of other basic estimates.

The visitors were taken underground in the morning, and to the dredge in the afternoon. Mr. Hutton, who is in charge of the dredging, did not describe the operations in the paper he read at the evening session; instead, he discussed discrepancies between drilling and dredging in general, quoting figures to illustrate the unaccountable differences that endanger estimates of the results to be obtained from dredging enterprise. His statements were confirmed by Messrs. W. H. Gardner and James W. Neill, both veteran dredge engineers, who quoted from their own experience. No explanation at all convincing was forthcoming, so the principal contributors to the discussion were nominated as a committee to inquire and report on this technical problem, in the expectation that some light would be thrown on the subject. Mr. Higgins asked Mr. Hutton to take the chair during the latter part of the meeting, which closed with a hearty vote of thanks to Mr. Bulkeley Wells and his associates for their hospitality, mental and physical. Next day the visitors went underground in the Consolidated Virginia mine and saw some of the deeper workings, down to 2200 feet. It will be remembered that the deepest work-

ings on the Comstock are in the Union mine at 3350 feet below the outcrop, but the great production that made the lode so famous came, almost entirely, from above the Sutrö Tunnel, which cuts the lode at 1860 feet. The biggest bonanza, that of the Virginia and California mines, extended from 1200 to 1750 feet. It was found by James G. Fair when he was acting as superintendent for the adjoining Gould & Curry mine. He found rich ore in a drift that he pushed into the Consolidated Virginia ground, that is, he obtained his information by trespassing. Subsequently he, John W. Mackay, James Flood, and William O'Brien—the 'Big Four'—bought enough shares to win control of the 'Con. Virginia', as it was then called and ever since. For three years, 1874-1877, the Con. Virginia produced \$3,000,000 per month and paid dividends at the rate of \$1,080,000 per month. In 1876, Mackay, then the superintendent, took out \$6,000,000 worth of bullion in one month, in order to make an exhibit at the Centennial Exposition. This rate of production, of course, could not last. It did not. The Comstock flared and went out like a gigantic industrial torch. By 1885 it was decadent. In April 1899, when the present writer made his previous visit, only 150 men were at work, although the population of Virginia City then was about 3000. Now 600 men are at work, although the local community has dwindled to 1500. Today there is a manifest revival of hope and of life. Besides the new operations on Gold Hill, it is likely that a similar resuscitation will be started soon on the upper levels of the so-called middle group of mines, and that within a year there will be several thousand men at work at Virginia City. This re-opening of old and famous mines is of great technical interest because it will show to what extent it may be practicable and profitable to undertake similar operations in decayed mining districts in other parts of the world.

The Outlook for Gold

In reviewing the past operations and future prospects of the Crown Mines group, Mr. Samuel Evans made sundry interesting remarks concerning the demand for gold and its consequent appreciation in value. Mr. Evans was speaking as chairman of the company on the occasion of its annual meeting at Johannesburg; he is known to be an astute and sagacious man; therefore his views regarding the status of gold are worthy of record. He is of the opinion that, whereas the pendulum of prices during the War swung farther in a direction adverse to gold mining than it had ever gone before, it is now swinging back; it may, he thinks, go equally far in the opposite direction, so that there may follow a rise in the value of gold greater than has been experienced since the metal has been used as money among civilized peoples. Mr. Evans bases his belief on the fact that the world's production of gold has decreased 27% since 1915, and on the expectation that "in the course of the next few years" there will be a demand more intensive than at any time since it was established as the standard. He

asserts that "the desire for gold among the people of the Far East has been enhanced" during the War and since, and "the use of it for currency purposes both there and in South America has increased". He expects Russia to come back to a gold basis, as France did after the revolution. He believes that Austria and other European countries having paper currencies that have become almost valueless "will be obliged to abandon paper for gold". Indeed, he deems it to be "within the bounds of possibility" that the Crown Mines company may yet find it profitable to mine the 3 dwt. banket of the Main Reef. The ore-reserves of the Crown Mines are estimated at 8,132,000 tons averaging 6.1 dwt. per ton.

Concurrently with these pleasant suggestions from Mr. Evans there is published a report by Mr. H. F. Marriott, consulting engineer to the Central Mining & Investment Corporation, a company holding large blocks of shares in a number of the principal mines of the Rand. Mr. Marriott is an ex-president of the Institution of Mining and Metallurgy and is abundantly qualified to speak as an authority on Rand economics. He gives the following analysis of operations on the Witwatersrand in the last two years:

	1919	1920
Tonnage treated	24,013,038	24,096,277
Revenue	£34,297,431	£33,231,257
" per ton	28.53s.	27.58s.
Expenditure	£27,518,253	£30,814,801
" per ton	22.89s.	25.67s.
Working profit	£ 6,779,178	£ 2,416,456
" " per ton	5.64s.	2.01s.
Premium	£ 3,503,007	£ 8,885,380
" per ton	2.01s.	7.37s.
Total revenue	£37,800,498	£42,116,637
" " per ton	8.55s.	9.38s.
Dividends	£ 5,845,607	£ 8,275,708
" per ton	4.87s.	6.87s.

The tonnage and revenue show but slight variation, whereas the increase of expenditure is alarming, for it has diminished the operating profit by 66%. Indeed, mining on the world's premier goldfield would have worn a sickly look by this time if the 'premium' on gold had not come to the rescue, by increasing the operating profit from 2.01 shillings to 9.38 shillings per ton, and thereby permitting a distribution of dividends equivalent to 6.87 shillings per ton in 1920 as against 4.87 shillings in 1919, that is, an increase of over 40%. In regard to the question of cost per ton, Mr. Marriott quotes the following figures, which he gives in shillings, pence, and fractions thereof; owing to the fluctuations in exchange it is useless to translate them into American currency; we have simplified them by conversion into shillings and decimals.

Year	Wages		Materials	Other costs	Total shillings	Tons milled
	European	Native				
1915	4.8	3.0	5.69	3.18	17.57	10,405,000
1916	4.98	4.13	6.08	3.28	18.47	10,156,000
1917	5.50	3.89	6.41	3.78	19.66	9,359,000
1918	6.68	4.23	7.55	3.59	22.06	12,005,000
1919	7.38	4.19	7.86	3.93	23.36	11,267,000
1920	8.53	4.5	8.44	4.41	25.0	11,028,000
December 1920	9.2	4.8	9.2	4.14	27.34	807,000

It will be seen that the wages of European employees have increased 92% since 1915; native wages are 18% higher; materials have gone up 61%, and 'other costs' 39%. The enormous advance in European wages, says Mr. Marriott, "is out of all proportion to the remainder of the increases noted, and the anomalous position has been created that the total cost to the industry of the

European employees, who largely act in a supervisory capacity and constitute one-eighth of the total labor force, is nearly double the whole expenditure on the native laborers who carry out the work". These natives—Kafirs—work five hours per day only, and are prevented from becoming bosses over their own people owing to the 'color bar', which restricts supervision to white men. In Northern Nigeria, the employment of native foremen has been started, and it seems likely that a similar step will be taken in the Transvaal. The Chamber of Mines has suggested a cut of three shillings per shift in the wages of the white employees as from July 1, and we shall know soon whether they have accepted. Any adjustment of wages based on the profit made by the companies is rendered difficult by the violent fluctuations in the premium on gold, or, in other words, the value of the United States dollar, for, after all, the premium simply marks the discount on the pound sterling as compared with the standard unit of today—the dollar. It is a new experience for gold miners to find their product so variable in price; the mining operations on the Rand are far more speculative than formerly; the contention, so common twenty or thirty years ago, that the Rand stocks were absolutely sound investments suitable for widows and orphans, is absurd. In the United States, we have seen gold depreciated by the abnormal conditions created by a great war between many civilized nations, but, we have escaped the vagaries of a gold market such as obtains in London and Johannesburg today. Already we see signs of a returning appreciation of gold, and a renewal of interest in gold mining. The vaticinations of Mr. Evans may be too rosy for immediate acceptance, but that gold mining will come into its own again in due course we believe confidently.

Claims Against Mexico

Under the title of 'Claims against Mexico', Mr. Raoul E. Desvernine has prepared an excellent little treatise on the various aspects of international law that are applicable to the claims of citizens of the United States, or of other countries, for losses sustained in Mexico during the revolutions that have occurred during the last decade. Mr. Lindley M. Garrison, in a foreword, speaks cautiously of "entangling alliances", but emphasizes the desirability of closer commercial relations between nations and nationals. He contends that we of the United States have shown a reluctance to learn international law, particularly with reference to claims in respect of damage or loss; it is to be regretted that the inclination to confine ourselves to our own interests has led us to neglect the acquisition of knowledge concerning other countries, and of those broad principles of law that underlie international dealings. The size of our country and the rapidity of its development have tended to make us self-centred; extension of foreign trade, however, is causing a change. Mexico, Mr. Garrison avers, seems to be attaining her equilibrium at last, and it is to be hoped that she will soon resume her normal position in the

family of nations. Before this is possible, however, she must meet her obligations. The purpose of Mr. Desvernine's book is to elucidate the fundamental rules and considerations that govern the subject of claims, and to show the proper course to be taken in presentation and prosecution, in the hope that an orderly procedure will ensue, and that the demands will be met with fairness and equity. The book is offered by one who has a sincere belief in the possibilities of economic development in Mexico, a development that, unquestionably, is dependent upon a resumption of normal relations with other nations; it is recognized that the country cannot achieve success other than by the aid of foreign capital and foreign resources. Normal relations and normal development will commence only when other nations are satisfied that those of their citizens who hold claims against Mexico are likely to receive consideration and justice.

The essence of the present status of the question is summed up in the fact that, "The Latin-American countries have been the staunchest supporters of the theory of non-responsibility. They have been forced to this stand by the frequency with which they have been visited by insurrections, uprisings and banditry, and have, by necessity, been compelled to develop, through their statesmen and publicists, a justification for their reiterated attempts to deny liability." Mexicans fear that the enforcement of the obligation of international responsibility would lead to the acquisition of economic advantages by the citizens of the interposing nation; loss of sovereignty and independence is dreaded, but there is no justification in modern international law for the repudiation of responsibility. In the new Mexican Constitution of 1917 it is stated: "Only Mexicans by birth or naturalization and Mexican companies have the right to acquire ownership in lands, waters and their appurtenances, or to obtain concessions to develop mines, waters or mineral fuels in the Republic of Mexico. The Nation may grant the same right to foreigners, provided that they agree before the Department of Foreign Affairs to be considered Mexican in respect to such property, and accordingly not to invoke the protection of their Governments in respect to the same, under penalty, in case of breach, of forfeiture to the Nation of the property so acquired." This clause was considered by many Mexicans as one of the triumphs of the revolution that unseated Porfirio Diaz; in the opinion of the United States it is viewed as an indication of a desire to evade international duty, and so is ignored or denied. Mr. Desvernine's book contains an excellent summary of Mexican history from the time of the overthrow of Diaz until the inauguration of General Obregon; he discusses the nature of the successive governments and revolutionary bodies, as well as the liability of the present government for the acts of each, with admirable clarity. From an examination of the evidence it is shown that Mexico is responsible for the acts of all the administrators since the fall of Diaz, except those of Huerta, who was not recognized, in any official way, by the United States.

Prospecting

The Editor:

Sir—As you have invited the prospectors to give their views relative to the so-called decadence of prospecting, I will herewith submit my views.

I went with the rush to Leadville, Colorado, in November '79. I did my first prospecting on the head of the Pecos river, New Mexico, in the summer of 1880 and I have prospected at intervals ever since, but I am one of the prospectors that has never made a strike. It is a fact that there is a clash between the mining engineers and the prospectors. No matter what the mining engineer may think, he is a twin brother to the prospector. He has had the advantage of an education in our best colleges, which has enabled him to learn that which takes a prospector a lifetime to learn. There is no doubt but what there are mining engineers as well as prospectors that ought to be in some other business. The qualifications for an engineer should be honesty and a fearless courage to recommend a property just as he finds it. This kind of a man, if he does make a mistake and lose his position, will not stay down long, for his force of character will enable him to overcome all obstacles. This kind of a man and the geologist that understands his business are the best friends the prospector has or ever will have. I am willing to take off my hat to them for the great work they are doing. I believe the average prospector makes a mistake in submitting to hard bargains for his claims, but the claim-owners incorporate and issue stock to the amount of what the claims are supposed to be worth and concentrate their efforts on the best ground. There is nothing like self-help. The districts where veins cropped conspicuously or where erosion has been so excessive as to make tracing by panning easy have been prospected fairly well, but what of the great belt of acid lavas of the Tertiary epoch extending for thousands of miles north and south a greater part of the way through two continents, the deposits in which for the most part have suffered very little erosion? Here is where an education in geology is valuable to the prospector. The first thing for him to ascertain is whether the formations are such that mineral is likely to be associated with them. If he has any doubt on that score, let him send specimens to the nearest mining school or State university and they will gladly put him wise. No prospector should start prospecting in a district till he has ascertained what the formations are, observing the hydro-thermal alteration in areas that are well broken by faults or dikes and around the lower margin where the strata have been closed. Such a district as this may

show no ore on the surface. Watch the changes in the country-rock along such fractures, the addition of silica approaching the fracture; look for pyrite or stains of manganese oxide. There are many districts that contain no signs, but such conditions are caused by the lack of erosion. Most of the time for the last five years I have been prospecting in the very northern edge of Nevada and south-eastern Oregon. Of the prospectors I met there, not a single one took a mining periodical. Most of the old-timers I have met know very little about the ways of modern prospecting. Nobody is to blame for this condition but themselves. I am in favor of every State compelling its prospectors to register a reasonable fee for the same. A State that has a Geological Survey should have charge of this work and should have a list of all prospects and mines that are for sale. I am in favor of continuing the annual assessment work, but the prospector should be permitted to do the annual labor on all the claims he has or one claim if he desires to do so. As it is now, all mining men know that a great deal of this labor is wasted. Many prospectors are quitting the game because they have a lack of technical education. The present conditions are not good for old-time methods.

I have no grievance to register. I might mention a mischievous clause in the Ashurst mining law where it says "at the discretion of the Secretary of the Interior". This gives the prospector some red tape to uncoil.

C. H. McCUMBER,

Beatty, Klamath county, Oregon, June 16.

Zinc-Silver Ore Treatment

The Editor:

Sir—In your interview with Mr. D. W. Brunton and with reference to the treatment of "the middlings, which consisted of pyrite and blende" carrying "a large amount of silver", the following treatment was designed, quoting Mr. Brunton: "At the Stewart mill I found that when the ore carried a high percentage of zinc and was roasted at a low temperature, chloride of zinc was formed, which acted as an excellent solvent of silver." If we continue reading we find that at Silver Peak there was salt in abundance; but at the Stewart mill the pyrite and blende were roasted, and produced chloride of zinc, which dissolved the silver. The question is, are we to take this paragraph as written or is it wrong? How the chlorine got into the Stewart ore is not mentioned, or why, if roasted with salt, the silver should remain as silver and not as chloride. The paragraph may mean that at the Stewart mill the mixture of pyrite and blende

was roasted with salt at a low temperature, producing both chloride of zinc and silver; and the chloride of zinc dissolved the chloride of silver. Kindly elucidate this puzzle as some of us doubt that chloride of zinc is a solvent for chloride of silver or even of silver as stated.

Nayarit, Mexico, June 2. ALGERNON DEL MAR.

The Editor:

Sir—In reply to Mr. Del Mar's inquiry, I wish to state that the method of silver extraction (U. S. patent No. 228032), briefly sketched in the interview, was simply a variation of the Augustin process, in which the solvent power of the salt solution was increased whenever the ore, before chloridizing, contained blende, by the presence of chloride of zinc and incidentally by the chlorides of calcium and magnesia.

In the Augustin process, the silver ore, after being subjected to a chloridizing roast, was lixiviated in an ordinary leaching-vat; in the other method, usually dubbed 'chloride leaching', the hot ore from the chloridizing-furnaces was run directly into agitators and stirred until the solution was complete, a procedure which greatly expedited the rate of solution. That this method was a success is evidenced by the fact that all of the mills mentioned were operated at a profit until the available supply of ore was exhausted, during which time they produced many hundreds of thousands of ounces of bar silver over 900 fine.

D. W. BRUNTON.

Denver, June 17.

Metallurgical Methods at Rio Tinto

The Editor:

Sir—I have read with great interest Mr. De Kalb's article on cementation at Rio Tinto, and also Mr. Van Arsdale's comment on the same. Claiming some little experience in heap-leaching, I thought I might be allowed to contribute to the discussion.

Referring to Mr. Van Arsdale's simplification of the equation (1), which he writes as

why not simplify it further and write

as $2\text{FeSO}_4 + 2\text{H}_2\text{SO}_4$ is all that is required to carry on the good work. However, I think that the equation as given by Mr. De Kalb is the correct one:

the excess of 29FeS_2 , representing the large mass of un-attacked pyrite, which, as is well known, is later shipped for its sulphur content.

Mr. De Kalb refers to the first cement copper as being produced at Rio Tinto in 1752, from mine-water only. L. de Launay says* that the first cement copper was made at Rio Tinto in 1752, from heaps that had undergone a natural decomposition by atmospheric influences and that had been leached out by water, the copper being pre-

cipitated on iron. The process met with strong opposition from the then general superintendent of the Hacienda Real, Don Pedro de Lerina, who stated that the cement copper obtained was nothing more or less than iron coated with copper, and that this falsification would do a great deal of harm to the Spanish copper trade. After a long series of experiments by some celebrated chemists at Madrid, it was shown that the Don had made a mistake, but it took a long time before the lixiviation process was looked upon with favor. See also M. Eissler's 'Hydro-Metallurgy'. It might be worthy of note here, that cement copper was produced from mine-liquors at Schmollnitz in Hungary in the 15th century.

With regard to the washing of the heap, indiscriminate running on of solutions would never do. As Mr. De Kalb suggests, great care is necessary. The precept to be kept constantly in mind, is to obtain "the best product in the shortest time at the least expense". In other words, to get the maximum amount of copper with the minimum volume of solution. There is, however, a compensating balance at work all the time, and just when a certain portion of the heap may be getting 'cold' or 'drowned', other physical features present themselves, which indicate clearly to the superintendent in charge the urgent necessity of moving the wash-liquor to some other part of the heap.

Referring to Mr. De Kalb's statement on the solubility of zinc, that it does not precipitate in the vats, that is quite correct, but neither does it re-deposit on the ore, at least to any great extent, as it is found in large and almost equal quantities in the heading and tailing of the *canaleo* or cementation plant. Such was my experience for several years at Cuchichon.

I was glad to see Mr. De Kalb refer to the heap-leaching of siliceous and schistose ores, as that practice is particularly applicable to this country, and I regret he did not give us even more details, and further enlightenment on this feature of the method. At Cuchichon they treat a schist containing about 1% copper. Heaps are about 20 ft. high (6 metres). They are washed with water from the mine, augmented by some waste-liquor from the plant. The liquor entering the cementation plant carries about 5.50 lb. copper per 1000 gallons, and leaves with from nil to 0.16 lb. copper per 1000 gal., showing a recovery in the plant of more than 97%.

Mr. De Kalb gives the time necessary for leaching these siliceous heaps at Rio Tinto as ten years, which seems a very extended period. A siliceous heap at Bisbee, 20 ft. high and containing about 13% copper when built, showed an extraction of close on 73% in three years—a slight improvement on Spanish practice.

I notice that in Spain they still cling to the idea of many kilometres of shallow canals for precipitation of copper from solution, while here deep vats with false bottoms and stirring mechanisms are being considered as the best vehicle for such work. In fact, the vats have already shown themselves to be most economical and efficient.†

*'Annales des Mines; Memoire sur l'Industrie du Cuivre dans la Region d'Huelva', Paris, 1889.

†See 'M. & S. P.', Feb. 12, 1921.

While the Huelva-Seville district has long been regarded as the cradle of heap-leaching and natural cementation, it may be, as the child is sometimes father to the man, that in the not-distant future, our brother metallurgists on the other side, may study with some interest the heap-leaching and cementation plant results obtained in our South-West.

Jerome, Arizona, June 11.

JOSEPH IRVING.

Prospecting

The Editor:

Sir—With all due respect for the sincerity of the writers of recent articles intended to improve the lot of the prospector, I beg leave to put a few small flies into their ointment. Can any of these writers explain why a man who holds claims from year to year without much actual benefit to them should be protected by law in so doing? Such a claim-holder dare not defraud a neighbor or group of individuals without fear of trouble; yet he is well protected in defrauding 110,000,000 fellow citizens, who seem to think that he needs protection in defrauding them still more. What else can you call it if the requirement of annual assessment work be stopped altogether, as some think necessary to solve the puzzle?

I admit that a large proportion of mining claims, both locations and patents, are being held for speculation. Every business has some speculation in it, and mining has always and everywhere been more speculative than perhaps any other business that has need of scientific knowledge. I also know that much territory for grazing of stock is meant to pay its real profits from mining leases and sales in the event of the finding of a paying vein on the property. This has been done often in Calaveras county, and also in other districts to a smaller extent. The patentees take advantage of the fact that patent titles cannot be reversed, because of error or fraud, after seven years. The grazing furnishes an ordinary profit on the use of the capital required to obtain patent and to fence.

The only possible way that a prospective buyer can have protection against imposition in dealing with owners of small undeveloped prospects and wild-cat properties is by being slow, cold, thorough, shrewd, and independent. Anyone who cannot so qualify as such is foredoomed to failure. Even if qualified, he may make an expensive mistake, because he is still handicapped in other ways. But that is not my subject. I have studied the Mother Lode country since coming here and have experiences to remember.

To get back to speculation in mining claims: the real unfairness can be remedied by the 110,000,000 people when they assert their sovereign rights of ownership to all mining locations, by requiring every 'proof of labor' to state where assessment work was done and how it benefited the location to the extent of \$100. As the 'proof of labor' now operates, it need include no definite statement in a case of fraud as to where or how there was benefit, or an outlay approaching \$100; it puts the

burden of proof upon the true owner to show that he did not fulfil his full duty in trust. There is now little chance of true proof of fraud.

The honest locators and holders often leave their locations, vowing that they will do no more work on such worthless property; or they do their work regularly and tell about it, and may disdain to file 'proof of labor' as evidence that they are honest men. The dishonest ones hold on and on, filing 'proofs of labor' because no one can watch any of them for 365 days in any year; and no one is able to swear that no work was done. The courts have been favoring any claim-holder who can prove that he did any small part of his \$100 worth of annual work or permanent benefit per claim. The principle is right, but the practical application is usually wrong. It is wrong for a 'proof of labor' to be admitted as direct evidence when not sworn to; California requires that it shall be sworn to before being admitted as evidence in her courts.

The remedies of the abuses stated in this letter are manifestly the business of the legislative branches of each State wherein is the greatest hope of correction. It is far more customary for the dishonest location holders to file 'proofs of labor' than for the honest ones. Many an honest locator or location holder depends on the added improvements to prove his annual assessment work; he is proud of what he has done and demands that it suffice. A trick practised at times is to freshen the surfaces of weathered dumps and excavations, to indicate that assessment work has been done!

GEO. E. McCLELLAND.

Sonora, California, June 6.

The Editor:

Sir—It is with intense interest that I have read the contributions regarding prospecting in your recent issues. I believe Mr. Davis is right in his statement that "we have spent too much of our time . . . on small streaks". It indicates one of the main reasons why so few mines of consequence have been discovered in recent years.

Most prospectors put in too much time on the smaller veins because there is a better chance to find high-grade ore, and there is always a better opportunity to sell such prospects, or at least to induce others to furnish funds for further development, even though the ore does not occur in paying quantity. On the other hand, the prospect that has "the earmarks of a big mine" seldom has ore of shipping value near the surface, and it is almost impossible to interest capital in its development, unless it is near, very near, a booming camp.

The development of this class of prospects will certainly help the situation, as it will encourage the prospector to look for them instead of chasing high-grade streaks. No doubt the promoter, on whom the prospector frequently depends to get his wares to market, is largely to blame. He is seldom a mining engineer, or familiar with the geology of ore deposits, and it is much simpler to raise funds on high assays than on even the

most favorable geological data. He naturally prefers the proposition that promises the largest returns for himself, and producing mines are not a necessary adjunct to his operations. Higher commissions are paid for financing prospects than for any other purpose. A better system of financing prospects is certainly necessary if individual effort is to survive.

If these changes cannot be brought about, prospecting as a gainful pursuit for the individual is likely to come to an end, except possibly for those few fortunate individuals who are possessed of the "inevitable requirements" enumerated by Mr. Davis, and sufficient financial backing.

W. F. KOFF.

Coloring of Glass

The Editor:

Sir—Assuming that the letter of Mr. Francis Drake on this subject in your issue of June 11 invites an explanation of the phenomena of colorless glass turning purple in prolonged sunshine, I venture to mention the deductions I formed many years ago as to the cause of the coloring.

Manganous compounds are pale-pink in color; manganic compounds are violet in color; permanganic compounds are purple-red in color. Compounds of manganese produce an amethyst color in the borax-bead (manganic borate); in the reducing flame this color disappears (manganous borate). These chemical reactions are well known and simple, but are mentioned as being essential to understanding of the cause of 'amethyst' whiskey-bottles.

In the making of colorless glass, manganese dioxide is added to oxidize the green ferrous silicate, caused by traces of iron in the sand, to the almost imperceptible pale-yellow ferric compound. The faint-pink tint of manganous compounds in the glass also tends to mask the pale-yellow color produced. This explains the so-called colorless glass, but the actinic action of the sun's rays, or of an intense arc-light, changes the pale-pink of the manganous compounds to the strong violet or purple of the manganic or permanganic compounds. The reactions involved may be more complex than here indicated, but the explanation will suffice for the present purpose.

The opical glass used in projection lenses in the 'movies', under intense light, is rapidly turned amethyst or purple in proportion to the quantity of manganese dioxide used in its manufacture; similarly, the eye-glasses made to relieve the eyes from sun-glare are colored faint or strong amethyst at will by varying the quantity of manganese dioxide used, but in this latter case instead of waiting for the slower actinic action of the sun's rays, the glass is placed under the intense action of strong electric light, which does the work in a comparatively short time. Arc-light globes in our city streets and elsewhere are turned amethystine in the same manner. Probably, if the Boston residents knew how rapidly their old

violet-colored windows could be reproduced, they would not feel so proud of them, but it would be a pity to apprise them of the fact.

Finally, your own joenlar foot-note may be further played upon by giving the definition of amethyst, that is, resisting wine, the Greeks believing the stone and plant of that name to be preventives of intoxication.

Los Angeles, June 14.

R. D. PERKINS.

The Editor:

Sir—The letter from Mr. Francis Drake in your issue of June 11 mentions a fact that has long been observed in certain kinds of glass. I remember, as a child, visiting an old farm-house and out of a dozen drinking-glasses, five or six of them were decidedly violet in color. I was never content unless I had one of these "purple glasses" at meal times, although they were considered inferior by the rest of the household. Later, I observed this same phenomenon in milk-bottles, fruit-jars, and, once or twice, in cut-glass. The windows at the farm-house mentioned above also had a decidedly purple tinge and this color was always a source of mystery to the people thereabouts.

The following excerpt from Thorpe's 'Outlines of Industrial Chemistry', 3rd edition, pages 198-199, gives the cause of this phenomenon: "It is customary to employ other ingredients in every glass mixture, to assist in the decolorization or fusion. The commonest decolorizing agent added is pyrolusite (binoxide of manganese, MnO_2). Iron, when in the *ferrous* condition, imparts a green color to glass; but when in the *ferric* state, it is much less troublesome, since it gives only a pale yellow color. By the oxidizing action of the pyrolusite, ferrous iron is converted to the ferric condition; moreover, the silicate of manganese has a violet or pink color, and so helps to neutralize the green. Only a very small percentage of pyrolusite should be thus used. The remedy is not a permanent one, and *if the glass is exposed to strong sunlight for a long time, it develops a violet shade, as may often be observed in the window panes of old houses.*"

The fact that this phenomenon occurs most frequently in 'potash' glass (glass having a potassium carbonate base) has led some investigators to believe that this coloration is due to the potassium present, which undergoes, in strong sunlight, a change of state that is not, at the present, fully understood. Other investigators hold that the change is partly the result of pyrolusite and partly of potassium. It has, however, been clearly proved that pyrolusite must be present wherever this color change occurs.

FRANK J. G. DUCK,

Assistant Principal, School of Metallurgy.

Scranton, Pennsylvania, June 14.

According to figures compiled by the U. S. Geological Survey, the quantity of salt produced in the United States in 1920 was 6,965,188 short tons. The value of the product was \$30,539,168, or nearly \$3,500,000 more than any other year.

Training for Foreign Exploration

Commencement Address, Missouri School of Mines, April 29, 1921

By H. Foster Bain

Mining engineering occupies a borderland. In common with other branches of engineering, it is an "art and science by which the mechanical properties of matter are made useful to man in structures and machines", but with a difference. The civil engineer digs a hole to put something in it, a foundation perhaps. The mining engineer digs a hole to get something out of it, the ore. If he puts anything into the hole, timbers to support the excavation perhaps, he does it grudgingly and always with a view to the utmost economy of material. He cannot, as can his fellow professional, build with an eye to the long future. He must always face the fact that his main object is to get things out of holes, and that when he has got out of the hole all that Nature had put in it, neither the hole nor the plant used in the work has any further value. There is but a modicum of salvage upon which he may count. In many particulars his work shows analogies to that of the contractor, and the same logic that leads a contractor to low first-cost installations is good, within reason, for the mining engineer. He does his work and moves on; and there is probably no profession calling for equal skill and learning, in which the members wander more. Always they are seeking or extracting or utilizing material forming part of the crust of the earth, and usually are doing it under conditions or with equipment that is at least suggestive of being temporary. The mining engineer must improvise, and he must be versatile. Of him it may be written as Kipling has of the marine:

For there isn't a job on the top o' the earth the beggar
don't know nor do,
You can leave 'im at night on a bald man's 'ead to
paddle 'is own canoe;
'Es a sort of a blooming cosmopolouse—soldier and sailor
too.

To the lore of the geologist he adds the skill of the engineer and the science of the metallurgist. Always and everywhere an eclectie, he adapts means to the end. Clearly where there are such varied duties and opportunities, room for specialization exists; and this is, indeed, the fact.

Mining engineers, employing that term in the broad general sense in which it has common usage, are called upon for three sorts of work: (a) geological, (b) mining proper, and (c) metallurgical. No one man may be expected to be competent in all three, and each branch is really a profession within a profession, but a man who stays long and achieves success in mining engineering must know something of all three, and young men who

leave the schools, regardless of the point of the triangle at which they begin, seem in practice liable to end at either of the other. Each of the three has applications outside mining, or verges over into other fields. Thus the border-line between metallurgy and chemical industry is shadowy, the ties between mining engineering proper and civil engineering are many and close, and geology is a broad science which touches many fields aside from those related to ores and minerals. It is, however, the light that geology throws on the genesis and especially the occurrence of ores and minerals that interests the miner, and it is in finding minerals and guiding development that it is of most direct benefit to him. This work is fundamental to mining. And it is the work of the exploration engineer. It may be of interest to inquire as to the probable future demand for his services and the training necessary to qualify him for service.

Mines are wasting assets; the very life of the mining industry is dependent upon the continual finding of new mines, new orebodies, and new reserves. When this stops, mining will stop, though the death may be a lingering one. Whatever may be true as to a particular type of mining or mining in a particular locality, it must further be clear that so long as man persists on this earth he will have use and need for some portions of its crust and that, therefore, mining in some form will continue. Each individual mine, be it ever so long-lived, is eventually worked out and becomes worthless, and other mines must be found to take its place. The emphasis changes and minerals or metals eagerly sought by one people or one generation are less important to those who come later, sometimes because their wants are supplied from a different source. In the early settlement of the Mississippi Valley local salt-supplies were so important that salt lands were generally set aside as being of particular value. Now these local supplies are of so little importance that they are generally not worked. Nonetheless the salt industry is manyfold larger and more important than was contemplated by our grandfathers. The human need for salt is as great as ever and with increasing population more salt, and hence more salt mines, have been needed.

As there comes to be more people in the world there will be more need for mineral products, and, disregarding the substitution of one for another, the minimum rate of increase in output for the minerals as a whole may be safely taken as that of increase of population.

There is an additional factor that lends assurance to the future of mining. As civilization spreads and industrialization becomes increasingly intensive, the per

capita consumption of minerals increases. Man comes more and more to depend upon energy taken from the earth to supplement his own labor. The brilliant civilization of the Greeks was based upon slave labor. It is worth remembering that in the golden age which the classicists so love to recall, the mines of Laurium, worked by slaves, were so productive that each citizen of Athens received a dividend in place of an annual tax-notice. Naturally, they had time to sit around in the sunshine and talk philosophy. The people of our time will not tolerate slavery. We have found a better way in that we harness to our use the energy of falling water and of fuels, and so are each served by invisible non-consuming geni of the earth. The peoples who make the most use of earth materials and forces are the peoples who work the shortest number of hours, produce the most goods, and have the most to divide among themselves. There are great differences between the peoples of various countries and centuries in this particular. Probably the civilized man, on the average, eats little if any more food than his ancestors did, but he does burn more coal and use more metals. Even among the various peoples of the present there are differences. The Chinese use about 1/20 ton of coal per capita per annum. Americans use approximately 6 tons, and other peoples use various amounts between. Generally speaking, the world is learning to use more and more coal and so to substitute the mechanical energy of heat for human labor. The pre-war per capita consumption of copper in the United States was 6 to 7 pounds and for France about 1/4 pound. In Russia it is very much less, but nothing can be more certain than that through a term of years peoples of other countries are going to approximate more closely to American standards of consumption. The United States is by no means the only country where modern plumbing is appreciated, and as the cult of the bathtub spreads around the world the consumption of the metals will grow. This demand can only be supplied by re-use of old metal or by making additions to the world's stock. Mineral wealth, fortunately, is not necessarily consumed in use. There is wastage, but there is also salvage, and large amounts of old metal are continually returning to use, so much so that important metallurgical processes such as making open-hearth steel and cement copper are based upon supplies of scrap metal.

The existing stocks of the various metals represent accumulations of all the centuries that have gone before, though very much the larger part has been won within the last hundred years. There have been times in the past when but little was added to the stock and there have been peoples who merely captured in war and used the metals mined by others. This was true of the Tartar dynasties in China. The peoples who ceased to mine ceased to progress in civilization and the great civilizations of the past were those in which the people laid under tribute more and more of the earth.

As yet no people are known who have accumulated a sufficient stock of metals to supply themselves by remelting and at the same time to make progress in civili-

zation. Having regard to the many activities that led to wastage, it seems improbable that any active people will reach the stage where they will not require periodic additions to their stocks of metals. In the opinion of economists, also, no active people have yet reached a point of saturation as regards even steel, the most common of our metallie alloys. It seems, therefore, safe to assume that demands for minerals will continue to increase. Two methods of meeting this increasing demand are known. By improvements in technology and financing it will be possible to lower the limit of metal content which separates ore from waste and so increase the reserves in known deposits or make into ore deposits what are now mere mineral segregations. This is a fruitful field and calls for application of the highest type of skill and genius in our profession. It is one in which remarkable results have been achieved. Working 1% copper ores means handling 2000 pounds of material to recover less than 20 pounds of copper, for even the best practice involves losses. It is only possible to do this by application of excellent technology and remarkable powers of organization and financing. In producing helium from natural gas a raw material containing less than 1% is used and the technology involves incursions into low temperatures and high pressures not previously applied on any large scale outside physical laboratories.

A second way to meet the future demand for mineral products is to discover new deposits either of types made profitable by the improvements of process and business organization just mentioned, of types long known, or of new types. Fortunately there are opportunities of finding all three, and in all this work exploration enters. The search for 'porphyry coppers' has been a wide one. Beginning in the United States, it has long since spread into foreign fields. It has led men into many of the odd corners of the earth and there are regions yet to be explored. In conducting this work, knowledge of the widest character is desirable. When C. G. Gunther began his search in Mediterranean countries, which has resulted in the development of an American mine of promise on the island of Cyprus, the first step was a reading of the classics. The Romans and earlier rulers of the region had sources of copper which, while small as judged by present American standards, might, it was thought, well point the way to a source for modern production. It will be recalled that the Utah, Chino, Ray, Nevada Consolidated, and other of our modern enterprises were built on older small-scale undertakings. Seeley W. Mudd, the eminent mining engineer who studied in a Missouri school and began his professional career in a Missouri copper mine, had the vision of applying in the Mediterranean region the knowledge which had grown out of American experience. He and his associates found in Mr. Gunther an excellent and enthusiastic agent. The work began, as I have intimated, with a careful review of the classics and was followed by field studies first in North Africa and later in Asia Minor, where old mines offering promise of profit under modern methods were found. I cite this instance to enforce the

observation that no knowledge comes amiss to an exploring engineer. I hope it will not be construed into an argument for making Greek and Latin required courses in mining schools, but it does show that wide learning is of real value to a mining-man who purposes to do more than conduct a local and minor operation. As for Greek and Latin, mining-men as well as others who can without undue sacrifice of time become acquainted with them, will gain by doing so. It is well, though, to preserve a sense of proportion and mere knowledge of foreign languages, ancient or modern, hardly qualifies one to assume responsibility as an operator or advisor in mining. Indeed, a surprising amount of work can be done through interpreters, since to a good geologist the rocks speak direct and a competent miner or metallurgist can piece together the story of old works and furnaces from scattered remains, drawing inductions as surely as does the vertebrate paleontologist from a few bones. Get all the knowledge of modern languages that circumstances permit. Some have a facility in this which carries them far, but remember that it is but a means to an end. In the course of a recent professional trip, lasting some twenty months, business took me into countries and regions where eleven distinct languages or dialects were used, so distinct that for each interpreters were necessary. If I had stopped to learn each language before transacting business I would never have found time to do the work for which I was sent. Such experiences are not unusual in these modern days of wide travel. It is helpful but not necessary to know modern languages. Even when no interpreter is available, a few simple words will carry you surprisingly far. It is not only that they are useful in themselves, but they help to establish friendly relations. People generally take it as an effort to good understanding that you have tried to become qualified to talk to them in their own tongue, and words in any language carry an accumulation of associations which is left behind in translating. You must, however, depend largely on yourself. Use your eyes and your feet. Get out into the field and observe. Leave, if you must, puzzling questions as to labor-supply, laws, and regulations until you can get a competent interpreter, but for the facts as to character and extent of the deposit you wish to see, depend on your own powers and energy.

I am speaking now of language study as a means. Language and the whole group of so-called cultural studies have another use, one not to be overlooked. If you purpose to be an exploration engineer you will spend much time away from home, often under most un congenial surroundings. I once asked a young man returning from an outpost in West Africa what he considered most important for one to have before going into such work. I was a bit surprised when he answered, "a college education". Experience had taught him that a well-stored mind is the best companion, not only in solitude, but of a man surrounded by primitive and brutalizing conditions to which he does not wish to succumb. It has been my experience to note young men of good ante-

cedents who have dissipated and become mere brutes when left alone among savage or nearly savage people for lack of mental reserve. Mental balance and mental resources are of peculiar value as stabilizers under such conditions.

Search for 'porphyry coppers' and similar deposits will almost certainly carry you into regions of ancient mining. It is well to be on your guard neither to underestimate nor over-estimate the older civilizations. The ancient miners did many things well. They are apt to have exhausted the bonanzas down to water-level, and high-grade ore in old workings is rare. Their costs were low, since the mines were operated mainly by slave labor. It does not follow that because others worked a mine for centuries or even because it yielded a considerable aggregate of metal that it can be profitably exploited under modern conditions. With primitive tools the ancients accomplished wonders. There is, however, one assumption that it is usually safe to make—they did not work far below permanent underground water-level, since no amount of human labor quite accomplishes the work of modern pumps.

Just as we must remember that price relations of labor and metal were in ancient times very different from those of today, so we should bear in mind that in the past people were satisfied with amounts of metal that would be considered insignificant now. E. C. Eckel has pointed out that at the time of the discovery of America the total amount of gold accumulated in Europe in all forms was worth less than \$100,000,000, and that up to the American Revolution the iron made annually in this country was but 15,000 to 25,000 tons. Even at that it was equal to the output of England. Many deposits which would satisfy such demands are of no importance whatever under modern conditions of business and technology. Whole groups, therefore, of ancient workings may be passed in review quickly once you are satisfied as to their type and average extent.

Finding deposits suitable for large mining enterprises is, however, not the whole of the work of an exploring engineer. He may be employed to look up sources of some mineral that does not occur in large bodies, such as tungsten or vanadium. In such cases, little bodies must be regarded as jealously as are large ones of cheaper metals. A due sense of proportion is of high value to him and an intimate knowledge of the mode of occurrence of the mineral he is seeking to find is a first essential. Placer gold has a natural habitat and there are characteristic differences in types of deposits which may be correlated with the character of the country-rocks, the extent of their metamorphism, the presence or absence of intrusives, the character of the latter, the physiographic history of the region, and similar geological features. Much is known now of metallogenic provinces and something of paleogeography. All this and more is useful to one engaged in finding ore.

In estimating the value of professional knowledge necessary for success as an exploring mining engineer, I would, therefore, place a good working knowledge of

geology first. This should extend not only to the technic but to the sources of information and to current knowledge of the geology of the region to be explored. A metallurgist or a mining engineer engaged in the operation of properties does not need so comprehensive an understanding of geology. It is sufficient if he knows the general scope of the science and the particular ways it may be applied to problems he must face. It is by no means necessary that he should be versed in its technique, since there will always be within reach men skilled in the art who may be called to his assistance. What he should know is when a geologist can be helpful and how to use him in his work. It would be better for such men to concentrate their time and energy upon acquiring a complete mastery of their own work rather than an amateur and probably misleading knowledge of geology.

In the case of the exploring engineer the case is different. His prime function is to find ores and to do this he must know orebodies and the laws which govern their occurrence. These laws are imperfectly understood, much regarding them remains to be learned, and to resolve these doubts calls for the most complete knowledge obtainable concerning the principles of geology, the history of the earth, and the technic of making geological studies. It is therefore important that the exploring engineer should be first of all a well-trained geologist, one capable of observing, recording, weighing, and judging the numerous facts of which account must be taken in making his determinations.

Much observation has convinced me, though as to this there are differences of opinion, that it is better if he learn his geology first as a scientific study. There is a high value in the detached point of view of the man who loves science for its own sake and counts truth as most important. Men so trained have usually more vision. They have a wider knowledge of the literature of the subject and of the work of others. They are less eager to accumulate only the facts of immediate importance and so have more facts and more theory upon which to fall back when in difficulty. They do their better work because they look over the whole problem first. Not infrequently they make large savings by eliminating unprofitable work through preliminary study of literature. For all these reasons I would recommend the man who purposes to devote his time to exploration to study geology first and to study it as though he expected to be a professional geologist.

This, however, is not alone enough. It requires but little knowledge of the field to recognize that many serious mistakes have been made through relying on the advice of geologists. For this particular work of finding ore is needed more than the usual equipment of a good geologist. The latter is rarely versed in economics, and this is almost equally essential. Too many geologists have no adequate understanding of the relative importance of things from the miner's point of view. Not being trained in assuming financial responsibility for mistakes, they are cheerfully optimistic when to be unduly so invites failure. Their first tendency is to general advice and all

too promptly they will sketch out plans for development that call for millions when perhaps thousands alone are available. The geologist therefore needs further training before he is properly prepared to advise regarding mining development.

When the prospective exploring engineer has completed his scientific studies he needs help and criticism from his fellows, the mining engineer and the metallurgist. It is not necessary that he should become equally learned in their branches of the profession, but it is essential that he have a clear conception of the scope, character, and limitations of their work. It is his business to find the ore which the mining engineer shall mine and the metallurgist treat. Clearly no one will be profited by his finding and mapping metalliferous segregations which cannot be mined or are not amenable to treatment. It may be highly interesting and of great scientific import to map such bodies of mineral, but that is the function, among others, of the geologists of official surveys. The exploration engineer must work to find something out of which a profit may be made or he has not found ore. Clearly he must know, at least in general terms, the limits of cost which separate ore from rock, and he must have some well-defined idea of the technical difficulties to be overcome in mining each particular deposit and of the methods likely to be applied. It is not necessary that he should be able to make the application. That calls for skill of another character, but he must know, and know surely, that some one of several methods, perhaps, may be applied and must be able to approximate the cost. It is useless to find and drill placer-ground where the boulders are too large and numerous, or the bottom too hard or pinnaled, to permit dredging while the supply of water, of storage space, or the grade prevents hydraulicking or sluicing. There are dry placers, it is true, but if the exploration engineer finds conditions so unfavorable he would do well to defer drilling until after taking expert advice as to methods and costs of dry washing. It is also useless to spend money on a careful examination of a placer property unless there is reason to anticipate that the gravel will yield as much or more than the cost of working elsewhere under similar conditions. To determine this, one must know what constitutes similar conditions and what usual and unusual costs are. It is no part of the ordinary training of the geologist to accumulate such data, and if he is to succeed in exploration he must draw on the experience of the engineer, for it is either by serving an apprenticeship under him or having always a competent engineer as an associate. The latter is not always feasible and it is greatly to the benefit of his future if the geologist will serve for a time as helper to a good engineer in operating or examination work. It will help him to get into the habit of quantitative thinking and he will learn much of the law of averages. For one thing, engineering methods of sampling are on a much sounder basis than are those of the geologist. It is one of the minor tragedies of scientific work that so much high thinking is done over non-representative samples. Geologists generally have the same naive confidence

as has the prospector and promoter in their ability to take a 'grab' sample which will be representative, and this is a common source of error and disappointment.

Having said so much in disparagement of the profession which I have long loved, let me add that in the study of placers there is no knowledge that entirely compensates for lack of clear conceptions of geologic history and skill in geologic interpretations. Placers are the products of rivers or beach action. Their accumulation is an incident in river, lake, or marine history and may be closely correlated with the physiographic history of a region. There are definite places at which they may be expected to occur and others at which it is useless to seek them. Frequently they relate back to ancient rivers and to physiographic stages in the past whose marks, obscured by later changes, may be picked up only by the skilled eye, and of which the evidence may be correlated only by an active well-trained brain. To indicate the need of supplementary training and experience is not to discredit what is sound and useful in that already given to geologists. While I have drawn my illustration from the field of placer mining, a similar argument may be made in the case of lode mining, where structure, secondary enrichment, and other phases of geology are equally important, but where also it is necessary to know in outline of mining methods, especially of the critical limits, both technical and financial, of their application. The situation is the same in exploration for gas and oil, except that petroleum technology, being newer, is not as yet well formulated and the financial limits are more elastic. The rewards of success in oil and gas production are so much larger in proportion to the immediate investment, and the returns are so much more prompt, that it is not possible to estimate probable costs as closely as in other forms of mining.

Consideration of costs leads one into the larger field of economics, a popular branch of learning just at present. Aside, however, from this new general interest in what was once called "the dismal science", and belief in its applicability to present-day problems, there are permanent reasons for the exploring engineer acquiring more than a slight acquaintance with economics.

Minerals are the raw materials on which are based numerous industries and the conditions which limit their use are the same in many particulars as are those which unduly aid industry in a given region. Security of title, stability of government, availability of labor, adequacy of financial support, these are all matters to be considered in exploration and they are also matters studied by economists. Here again the exploring engineer may to his advantage draw on a fellow professional for methods and data. His own training prepares him to judge as to the material. Matters concerning men and money are, however, equally important, since the test of his results is whether he has found something which may be produced with reasonable expectation of profit. The subject is too large for discussion here. I may merely mention a few items by way of illustration.

One of the assumptions too commonly made is that

low wages necessarily means cheap production. This may or may not be true. It is largely a matter of efficiency. If it requires, as it sometimes does, six miners of one race to do the work of one of another, it must be clear that paying wages in the ratio of one to six does not lower costs. Not only that, but the final cost of production with such 'cheap' labor will be higher because of the larger number of working-faces necessary in the mine, greater amount of equipment, the extra supervision and housing, the higher accident-ratio and other matters, all of which enter into the final cost. On the contrary, one must not conclude that raising wages cheapens production. It only does so when increased efficiency results from the added desire on the part of the men to hold their jobs, or when it enables a particular employer to attract better men from others. Generally added efficiency in labor is purchased at an increased cost per unit, just as the added speed of a fast steamer calls for more coal per mile than when driving at a slower rate. It is also to be remembered that there are natural inequalities in efficiency and in the economical rate of speed of work as between men. These can only be changed slowly. Another factor to be constantly kept in mind by the engineer is that one of the costs of a new enterprise is that of attracting labor to it from existing industries. It may usually be safely assumed that the people of any district are already employed. If they do not work, they generally starve. What they are doing may seem relatively unimportant to the visitor, but it assumes another aspect to them. It is necessary either to import men already accustomed to the industry, usually at material expense, or to tempt workers out of some other line into the new one and then train them to it. This requires both time and money. The importance of the time factor arises from its effect on the present value of proposed investment. To illustrate: deferring the initial returns for two years decreases by 14% the present value of a series of dividends running through 20 years at 8%, assuming accumulations at 3%. The actual result varies with the assumption of time and rate, but the essential fact is that mere delay is expensive. When this delay is coupled with upkeep charges it is even more serious. This whole matter of the possible and probable rate and continuity of production is one of first importance in determining the availability or value of any mine or prospect. Into it enters also the various questions of market. I have already indicated my reasons for believing that, whatever may be the depressing facts of the immediate present, we may safely assume a continued demand for metals. This demand will, however, vary from time to time both for the group as a whole, such variations being due to general causes outside the industry itself, but also as relates to each metal. It is necessary to study problems such as expansion of use, substitution, periodic demand, and similar matters far aside from ordinary class-room instruction. As regards a particular enterprise, it is necessary in fixing capitalization to make assumptions not only as to the probable average price of output during the life time of the in-

vestment but also the maximum and minimum to be assumed, the probable period of duration of each, and if, as is occasionally true, some guess can be made as to the impending swing of the pendulum, it will be of great assistance. A property is financed on the basis of average returns through an expected life determined by consideration of numerous factors. A company in which capital is so adjusted to income may nonetheless fail if not prepared to withstand a temporary period of low prices, while if high prices may be safely assumed in the near future it is possible to finance the enterprise from earnings to a considerable extent. There is one general rule, the old one that a "bird in the hand is worth two in the bush". This is sound not only because of the risk attached to the question of acquiring the two theoretically in the bush but because the one in hand, if a good hen, may lay eggs through the waiting period. The dollar of today is worth more, normally, than the dollar which is to be paid some years later, because it may earn for you interest meanwhile. This principle of the greater value of quick returns when astutely used is a great help in bargaining.

Just as any engineer starting for a far country carries in addition to instruments, food, and engineering supplies, a personal kit, so there are accomplishments that are as desirable if not necessary to the exploring engineer as his knowledge of mathematics and geology. He must know how to keep himself and his men in good health or his expedition will fail. He is the scout of industry and often the pioneer of civilization. When he goes into the wilds the health risk is often the greatest danger faced. Even when he goes to older settled countries, the conditions of life differ from those in his own home, and care is necessary. With care it is possible to live and work in almost any country. It is now known that where it is worth while to do so, even tropical jungle-lands may be made safe and sanitary. To do this involves heavy expenditure not warranted in exploration, so that the pioneers assume risks not necessarily met by the operating forces that come later. The exploring engineer would do well to look carefully to his own physical condition and watch closely the food, drink, and habits of his whole party. Learn and enforce proper rules as to camp sanitation. One careless man may wreck an expedition or cause long and expensive delays. It is generally true that the most suitable food is the food of the country, but the exceptions are numerous and the cost of a mistake serious. Until the facts in each instance are established it is a justifiable expense to use imported foods. Proper cooking will render safe foods otherwise dangerous, and moderation in eating strange dishes is a wise precaution. The American habit of drinking raw water is one to be indulged with discretion in regions of older civilizations, but safe water is easily obtained by boiling. It is worth while to pay attention to details such as these which seem small to those accustomed only to our own ways of living. A knowledge of the methods of first-aid and a few medicines is of great value. It is not necessary to go as far as Doc

Milliken who, as you remember, would "take that bracket saw and the mild chloride and his hypodermic, and treat anything from yellow fever to a personal friend", but a little knowledge of simple medicines will ease your way greatly in strange countries. Learn to ride, to shoot, to swim, and to handle a small boat. I need hardly admonish a young American these days to learn to run a motor-car, but the accomplishment common in the older days of country and village life are becoming rare. It is not always possible to ride up to a prospect in a Pullman or even in a Ford. In the nature of things, the finding of new mines will take one into countries where only other than mining industries have been developed, and in practice that means going into regions of country and village life. At times it means rolling back the centuries and living for awhile in the medieval ages. In such places one must know about horses, and mules—their habits, preferences, food, simple ailments, and capacities for work. One may, too, be called upon to use a gun, though far more probably to afford the party fresh meat than as a means of protection. To handle a boat or to swim may be a necessity at any time, though it must be admitted that in any country where small boats are used native boatmen are likely to be numerous and skillful. Skill in any of the forms of what we now call sport may well prove of first importance in an emergency and will always prove at once a means of relaxation and of establishing relations with strangers regardless of race or language. The latter is a matter of no small importance in work when the goodwill of the whole party and of the people of the country traversed is so important.

Lastly, I would urge that to be successful one should have something of the spirit of adventure. Unless new scenes and new faces appeal to you, unless you find joy in the long days in saddle or afoot, unless the cheer of the camp-fire means more to you than the clank of the steam-radiator, unless to you coffee does not lose its fine flavor when served from a tin cup, unless you can sleep between blankets and not think of their scratching, do not undertake exploration. If you must have a napkin and morning paper at breakfast, if you cannot write save at a well-equipped desk, if you are not happy except with your family and intimate friends, if you need see the 'movies' before you can go to bed at night, you will be wise to find a routine job at home. But to those who have a venturing nature adventures come, and if you are one of the elect who feel the spell of the Yukon, or the lure of the little voices, then go

"Adventuring! Adventuring! and oh, the sights to see
And little fires along the trail that wink at you and me,
Till the last adventure calls us from the old, the vain
desires,
To a way that's still untrodden, though aglow with little
fires,
Where no wanderer grows weary and a man is free to
roam,
Or hang his hat upon a star and call the planet home."

THE LEAD SMELTER AT MORALES

Mining Activities Near San Luis Potosi, Mexico

By Robert B. Brinsmade

The city of San Luis Potosi, the capital of the State of the same name, lies on the main line of the National railway from Laredo to Mexico City, and is the western terminus of the branch railway that ascends from the port of Tampico. Situated at an altitude of over 6000 ft. above sea-level, it has the climate of perpetual spring, which is usual at this elevation on the Mexican plateau; and, being in Lat. 22°, it lies on the northern edge of a semi-humid climate that makes the landscape more verdant than that of the northern border. With its population of 40,000, central parks, and handsome public buildings, it offers an attractive site for industrial plants. The city derives its name from the mineralized mountain of San Pedro, 20 km. to the east, thought to resemble the famous Potosi hill of Bolivia.

THE MINES OF SAN PEDRO. This town is situated on a railway of 3-ft. gauge built by the Cia. Metalurgica Mexicana to connect its works, near San Luis Potosi city, with the forests on the Gulf slope of the plateau at Rio Verde. Discovered by the Spaniards in the 16th century, the rich streaks in the outcrops were first worked, large quantities of lean ore being left underground, either as filling or as pillars. The lead ores were smelted in adobe blast-furnaces, and the silicious gold ores were reduced by amalgamation or leaching. A dump of charcoal discovered a few years ago was found to contain 2½ oz. of gold per ton—evidently the result of precipitation.

The early wealth of the district can be judged by the fact that the 20% royalty collected by the Spanish Crown between 1575 and 1863 netted no less than \$72,000,000. At the latter date an incendiary fire destroyed the timbering, and caused a collapse of the stopes in the principal mines, which remained almost entirely inactive dur-

ing the remainder of the Colonial period. The old stopes were finally re-opened by the Victoria adit, which was started during the War of Independence; but progress was slow until the general revival of Mexican mining in the 'seventies. In 1895 the construction of a modern lead smelter near San Luis Potosi enabled the mines to be again operated on the basis of large-scale production, after two centuries of almost complete inaction. Most of the old mines are now controlled by the Cia. Metalurgica Mexicana; and either by government titles or by lease, on royalty, of the properties of the Cia. La Victoria y Anexas, the company that completed the Victoria adit. The chief independent operator is the Cia. El Barreno y Anexas owning a mine that occupies the central part of the old workings and a cyaniding mill that has been run intermittently on silicious gold ores for over a decade.*

As may be seen from the sketch in Fig. 1 the geology of the *cerro* is simple. An immense laccolith of porphyry (hornblende porphyrite) has bored its way upward through the original sedimentary strata, and now appears as a wide dike-like outcrop on both sides of a central peak of blue limestone of Cretaceous age. There are thus three surfaces of lime-porphyry contact to explore for possible orebodies, namely, *K-c-f-g*, *p-q*, and *m-n*; but, curiously enough, nothing of importance has been found except on the first contact. The mineral zone seems to have been all discovered and delimited by the ancients, for modern exploration outside the old workings and in virgin territory has had little success. There are three classes of orebodies: (1) lenses, following north and south from *K-f* along the lime-porphyry contact: (2)

*'Ore Deposits of Mexico', by S. J. Lewis. 'M. & S. P.', Vol. 120, p. 444.

chimney-like veins in the limestone as *a-c*, *c-b*, and *d-f* which strike north and south and ascend from such contact nodes as *e*, *b*, and *f* to the surface; and (3) cross-fissures which occasionally connect the veins of Class (2). The best ore for smelting is that of Class (1) which, when in place, contains from 6 to 10% of lead. The old stope-fillings, as now shipped for smelting, contain 2 to 3% lead, under 50% of silica, 8 grammes of gold, and 200 to 250 gm. of silver per ton. The veins of Class (2) contain 60 to 80% of silica; when large, they are the richest in gold; when small, they consist mainly of iron oxides, poor in precious metal, like the fissures of Class (3). The dividing line for the content of FeO is about 50%; above that amount the orebodies are apt to be commercially worthless as far as gold and silver are concerned.

The main working adit for present operations at the Victoria group runs north and south in the porphyry from *e* (Fig. 1). It is provided with double tracks for

for 600 m. east to west. Much of the output consisted of old filling. The chunks of good ore were first picked out, the remainder being passed over 1-in. screens. The oversize was rejected; the undersize, with a high lime content and containing some gold and silver, was shipped. Power for the tramway, hoists, air-drills, and repair-shops comes from the distant Guanajuato electric supply system. The alternating current, of 3-phase and 60 cycles, arrives at San Luis Potosi city at a pressure of 70,000 volts, but for passage to San Pedro it is transformed to 15,000 volts. In the receiving-house at the mines the voltage is finally reduced to 440 for power, and 110 for lighting purposes. The water-supply depends on the impounding of the scanty local rainfall in dams and tanks; it is inadequate, and has to be supplemented by water hauled in tank-cars from wells in the San Luis Potosi valley at Kilometre 8 of the railway.

The present condition of the San Pedro camp is typical of many famous Mexican mining districts in that the cream of the rich ores near the surface was skimmed by the Spaniards. Nevertheless the ore deposits of the Cerro are so large and so numerous that modern methods of mining and metallurgy permit profitable operation, and at a rate of production many times greater than was attained in the olden days.

LEAD SMELTING PLANT OF CIA. METALURGICA MEXICANA. This plant is located at Morales, 5 km. from San Luis Potosi city, and is the terminus of the company's narrow-gauge railway to Rio Verde. About half of the ore comes from the near-by camp of San Pedro; the remainder is purchased from other districts. Its capacity exceeds 1000 tons daily, of crude ore that by means of roasting and blast-furnaces is reduced to base bullion for export to the lead-silver refinery of Monterrey, N. L., and medium-grade copper matte for sale to the Aguascalientes smelting works.

There are 11 blast-furnaces. A dust-flue connects with the furnace down-comers from the smoke-hoods on the feed-floor. The feed is shoveled by hand through long doors in the sheet-iron hoods, the charge being brought in barrows from the ore-bedding bin in the rear; the bottom of this is at the feed-floor level, the top being surmounted by the tracks that carry the entering cars of ore and fuel. Each furnace has a horizontal section at the tuyeres of 10 by 3½ ft. and operates with a 17-ft. ore-column under a blast-pressure of 24 oz. The hearth is enclosed by 16 cast-iron water-jackets, set six on each side and two at each end, each about 4 ft. high. A side-jacket has one 3-in. tuyere in its centre, and there is a total of 12 tuyeres per furnace. The nominal daily capacity of a lead-furnace is 100 tons; and this charge is handled by 3 feeders and 11 wheelers on the feed-floor, and 2 tappers and 1 boss on the slag-floor. The coke consumption is 12% for American or 15% for the native product; the usual slag contains 33% SiO₂, 28% CaO, and 28% FeO, with a ratio of CaO to FeO of 1 to 1. The slag is tapped intermittently into a steel fore-hearth, lined with adobe brick and set on wheels, whence it overflows into Nasmyth slag-cars that are hauled by light steam-locomotives to the

FIG. 1. GEOLOGIC SECTION OF SAN PEDRO

handling Koppel 1½-ton steel ore-cars which descend by gravity when loaded and outward bound. When empty they are hauled back by mules to the interior of the mine. Elsewhere the cars are also of Koppel make but have to be contracted in size in order to enter the shaft cages, and only hold 600 kg. The adit ears discharge into side-dump wooden cars—holding 4 to 5 tons—that are handled on the surface tramway, in trains of 10, by a Porter compressed-air locomotive. This tramway connects all the principal mines of San Pedro, and forms a feeder for the railway from Rio Verde to the smelter at Morales. Below the adit *e*, the lower levels are developed by inside vertical winzes. The cross-cut *c-h* connects the adit with the 'Hidalgo' winze *h-H*, from the bottom of which the cross-cut *H-b* cuts the lime-porphyry contact again at *b*. From *H-b* the 'Begonia' winze *b-B* has been sunk, from the lowest point of which another cross-cut *B-f* cuts the contact at *f*. Each of these winzes is 150 ft. deep and contains two single-deck cages running in balance from ¾-in. steel ropes, and handled by 15-hp. electric hoists, made by the Wellman-Seaver-Morgan Co. Steel-rope guides are used.

At the time of my visit, the Victoria mines were producing 12,000 tons of smelting ore monthly, and employed a force of 1300 men, nearly all of whom were working by the contract system. The zone of productive orebodies extended for 1000 metres north to south, and

LEAD BLAST-FURNACES AT MORALES

dump. The fore-hearth is 8 ft. long, $3\frac{1}{2}$ ft. high, inside its lining, and 3 ft. wide at the base, but only $2\frac{3}{4}$ ft. wide at top—to permit quiet settling of the matte, which is tapped from a side spout into cast-iron molds. Much of the base bullion must be liquated on a small reverberatory hearth before it is clean enough for shipment, the resulting scum being re-smelted. The first matte is passed through a jaw-crusher and rolls, and roasted down to a sulphur content of 2 or 3%. After this it is re-smelted with silver ore, in two special blast-furnaces, one of 250 and the other of 150-ton daily capacity. Before the cessation of operations in 1914, the second matte was concentrated in the blast-furnace, re-roasted, and charged into a small reverberatory, where, mixed with half its weight of raw 60% matte and silver ore, it was reduced and cast into anode copper for shipment to the Balbach refinery at Newark, N. J. Since the renewal of smelting in 1918, the second matte has been shipped to the A. S. & R. plant in Aguascalientes. Originally the matte was roasted in Bruekner cylinders, but these have been superseded by hand-rabbed reverberatory hearths, which are built of local stone and provided, in the hot zone, with a lining of fire-brick. They are 15 in number, of which 5 have 70-ft., and 10 have 60-ft. hearths. The fuel previously used was cordwood, brought from the forests of Rio Verde on the company's railway. Last year the wood fuel was replaced by crude oil obtained from the Gulf Coast.

The sampling mill takes, according to richness, every fifth, tenth, or twentieth shovelful of ore as unloaded from the railway cars. The usual hand methods of coning and quartering are used to reduce the sample to a size suitable for assaying. For preparing fine ore, flue-dust, and roasted matte for the blast-furnaces, two 6-ft. briquette presses, made by Chisholm, Boyd & White, are used. The briquettes are hard enough for smelting after air-drying alone. The main boiler plant is of 1100 hp., of which 500 hp. is obtained from two Cook vertical water-tube boilers, and the remainder from four Stirling hori-

zontal water-tube boilers. The blast is supplied by six Root and three Connellsville positive rotary blowers, all piped to a common main and operated by three single tandem-compound Corliss engines, made by Fraser & Chalmers.

BEFORE the Chamber of Deputies recently, M. Loucheur, Minister of the Liberated Regions, stated, according to a consular report, that when the French recovered possession of the mines in the Departments of Nord and Pas-de-Calais, 140 shafts were found totally destroyed and the workings flooded, 2800 kilometres of gallery had to be re-established, and a volume of water extracted estimated at 110,000,000 cubic metres. There were 18,000 miners' dwellings completely destroyed, and 12,000 partly demolished. Eight hundred kilometres of railway tracks attached to the mines was destroyed, as well as power-plants with a capacity of 383,000 hp. M. Loucheur estimated that the total cost of reconstructing the destroyed mines in the two departments will be from four to five billion francs. It will require almost ten years before the devastated mines can produce on a pre-war basis. In spite of the admirable work already done, thousands of dwellings must still be constructed, and about 100,000,000 cubic metres of water remain to be pumped out. By a law of July 31, 1920, special facilities were granted to industries, which have suffered as a result of the war, to float loans destined to permit reconstruction. In order to take advantage of this law, the damaged or destroyed mines in the north have combined to form the Groupement des Houillères du Nord et du Pas-de-Calais, a joint stock company with a capital of 50,000,000 francs.

SILVER DEPOSITS are found in Bulacan, Paracale, Cebu, Marinduque, and Mindanao, states a consular report. The establishment of a local mine would serve to stimulate interest in mining. Both China and India are on a silver-standard basis, thus assuring a near-by market for Philippine silver.

Conditions in Europe

By Lewis W. Douglas

The casual observer and traveler in Europe cannot but be impressed with two glaring conditions: a feeling of international suspicion, in cases almost approaching hatred, and, within nations, an attitude of unrest and uncertainty.

Two years ago, the eleventh of November, the most destructive and, certainly, the most costly war in the history of mankind came to an end—perhaps a tragic end. During the period of five years, in which entire nations were concentrating every effort on the ghastly business of killing, much more than material destruction was taking place. Old ideas, long held to be true, were being silently refuted; previously accepted conceptions were becoming no longer acceptable. Men were asking, and, if not asking, wondering “why” and “where”, and “how” and “whence”. People had had enough of the old order, and were eagerly searching for some new principle to which they might pin their faith.

And out of that chaos of thought there came a great idea expressed by a great idealist. He has made many terrible mistakes; for them he has recently been overwhelmingly denounced by the people of his own country, and yet withal, there is a quality of idealism about him which must eventually, if not now, assure him a seat in the gallery of the world's greatest men. That man, two years ago, and more than two years ago, enunciated a principle of international ethics which everywhere touched the spirit of man. The Armistice came. He went to Europe: he came, he saw, he conquered. Using his consistently most powerful weapon, he went over the heads of European diplomats and potentates. He addressed himself directly to the great mass of European peoples, and in turn he received a popular applause such as few if any men in history have been given to hear. He represented a great nation at a great peace conclave. Sitting alone among more than twenty-five warring factions, each schooled in the traditional diplomacy of secrecy, and subtlety, he drove through a principle of international conduct that, idealistic as it may be, impracticable as it is quite possible to be, appealed, if not to the crowned heads and premiers and Ministers of War, at least to the humble millions. And men thought “at last we have something that will tend to decrease the number of wars with their horrible toll of dead and wounded, and their annual drain on the resources of nations”. And men knew that such a principle, supported wholeheartedly by a great moral people, must live and bear fruit. Then there happened unto them what befell the Lady of Shalott: the mirror was broken, their illusion was dissipated; for the United States, the enunciator and one-time acceptor of high principles, had repudiated her code. Like Cain she now said “I am not my brother's keeper”.

Regardless of the possible tragic consequences to herself, the effect of that repudiation on European psychology was nothing short of tremendous. Lacking the moral support of a great nation, and lacking enthusiasm in her leaders, Europe has since reverted to the pre-war status of international feeling. France hates, or almost hates, England; England suspects France; both distrust Italy; Italy has no faith in either; and all are indifferent toward us. Germany is still beyond the pale; Russia is an unknown quantity; Poland has embarked upon a policy of aggression. The much advertised “solid front of the Allies” has been broken; France is saying, “We Allies are no longer united; go to, then; I alone shall enforce the Treaty of Versailles”. Such is the international condition in Europe. The principles for which we fought, and which we opposed to those of the Imperial German government have been forced under. We, the conquerors, have been conquered by that which we conquered. Imperialism is rampant. The foundations of another war are being surely though unsuspectingly laid.

But though Europe has been foiled in her attempt to lay hold upon a new principle of international action, the awakening caused by the emotional reaction of war is still shown in her search for some new principle of internal action. France is perhaps the only nation that is not seriously affected. The reasons are quite obvious. The French, despite their light, life-loving, and perhaps frivolous, point of view, are a serious and logical people. And so, when some hundred and thirty-one years ago, led by a few men, some of whom were great thinkers, and some of whom were disgraceful characters, they decided that the medieval order must change, they set to with a will and literally wiped the slate clean. The French Revolution, bloody as it was, ghastly and terrible as it must have been, was the logical result of years of medieval rule imposed upon a post-medieval society. And yet through it and by it France laid the foundation of a sound economic order. The great landed estates—a medieval remnant—were broken up and distributed in small lots; political control by the few gave way to political control by the many. The burden of a landed aristocracy was once and for all removed. There were no half-measures. The past was obliterated. And out of that chaotic condition there emerged a new State, based upon a new political scheme.

The industrial organizations such as we have in this country, and such as England has in some measure, have never appealed to France. It is always both difficult and dangerous to catalogue causes and effects. Nor is this truism any less true in the present case. Suffice to say, therefore, that there are, at least, two factors which tend to discourage in France huge industrial enterprises. France is an old centre of culture; the thread of that

culture has never been broken; she therefore accepts life as something in which the mere making of money plays an important part—in the sense that one must live—though an insignificant one—in the sense that to live is not to make money. Her every effort, consequently, is not given to the accumulation of tremendous wealth. And the corollary is that she is not interested in those forms of organization which tend to amass huge fortunes.

The first factor which apparently influences France against the tremendous industrial development is one of philosophy. The other is a matter of economic conditions, for France has never been—God grant that she may never be—a highly industrialized state. Had it not been for the Franco-Prussian war and the imposition on France of the treaty of 1871, in which France ceded Alsace and Lorraine to Germany, she might today despite her tradition and philosophy be a great industrial as well as a great agricultural country, for in Alsace and Lorraine are the iron mines that since 1871 have made Germany what France has never been. The small producer therefore still survives in France. He, together with the peasant farmer owning property in his own name, constitutes over a half of the entire population. Under such conditions in which the employed class is relatively so small, bolshevism can gain little headway, for one of the conditions essential to blind radicalism is the existence of a large supposedly oppressed proletariat. And so France, in spite of a few sporadic efforts to arouse a spirit of rebellion, remains comparatively free from disturbing internal conditions.

England, on the other hand, presents a striking contrast. For years many have admired the English for their ability to shun extremes. One order has gradually replaced, or partly replaced, another. There has been little bloodshed; there have been few revolutions, and such as there have been since the seventeenth century have been small and, in themselves, unimportant. There is now therefore in England a medieval shell enclosing a highly industrialized modern organization. That shell must be, and undoubtedly will be, broken. But the question arises, will the process of breaking extend deeper than the shell?

Already there are indications of a coming change. For many years the development of labor organizations has gradually, but surely, proceeded, until today more than half the laboring population is joined together in combinations. Originally those combinations were formed for the purpose of economic protection. That purpose, however, has changed slowly until it has now taken on a political phase. Witness the progress and growth of the Labor party, originally organized for the representation of labor's point of view (now, however, misnamed, for it represents little more than the liberal point of view); witness the attitude which labor took in regard to Poland; lastly, witness the political issue at stake in the recent coal strike. And so it can perhaps be safely said that English labor organizations, consciously or sub-consciously, have assumed a new character, and

that they have formed a new theory of control, political as well as economic.

The action of the coal miners presents a most interesting and, at the same time, a rather dangerous case. The situation was this: During the War, the control of the entire coal industry was transferred from the hands of the owners to the hands of the Government, and the power to regulate domestic and export prices for coal was vested, by Act of Parliament, in the hands of the President of the Board of Trade; wages, during the War, were increased in such a way as to make an addition to the original wage; and, further, twenty months ago the famous Sankey Commission imposed, upon the original wage and the additions made thereto during the War, another award; the wage system in the coal industry is now therefore so complicated that a higher mathematician is scarcely capable of figuring accurately the total wage for each miner. The President of the Board of Trade set and changed the domestic price of coal several times, during the last few years, but sold the export coal at the highest possible price, the profits from which were to accrue to the Exchequer rather than to the owners in the form of profits, or to the miners in the form of wages. The miners objected to wars and insisted that the profits accruing from trade in export coal were being expended on the maintenance of a war force; further they objected to the principle of indirect taxation; in addition, they have been advocating for some time past the nationalization of coal mines. Such then is the background necessary to a complete understanding of the issues at stake in the coal strike. It is not necessary to point out that therein the miners have expressed themselves emphatically on certain questions of governmental policy, both domestic and foreign, and that by so doing they have taken unto themselves a new rôle.

The reason for this action is not solely an economic one, nor is it altogether a selfish one. Certainly on the part of some of their leaders and associates it is not a selfish one. Labor, or rather particular groups of the labor body, felt, perhaps justly, that those in whom political power is now, and has been for some few decades, vested have failed in their duty to themselves, the nation, and the world. They see old hatreds, old jealousies, old policies recurring; they see little if anything done in an endeavor to stem the tide of those hatreds, jealousies, and policies. And so they demand for themselves an opportunity to direct the government. It is that demand, implicit in the labor agitation of England, which makes the issues at stake in the recent coal strike not only one of two shillings or not two shillings, but also one in which Canada, South Africa, Australia, New Zealand, the British Isles, in fact, the whole Empire is involved, and one in which are implicit the questions of economic and political control.

What with the pressing, more pressing, and ever more pressing demands of labor, what with Ireland knocking at the door and insisting on an unsatisfactory settlement for a historically dissatisfied people; what with the final disintegration of the Empire looming on the horizon, we

cannot but extend across the ocean to the mother country—for after all England is our mother country—a feeling of sincere sympathy and a hope that, just as she has “muddled through” crises in the past, so will she muddle through the present one.

Of Russia, few if any persons are entitled to speak. A veil of secrecy and mystery enshrouds her. We hear of the Whites, the Reds, rebellions and counter-rebellions. We read one morning that the Lenin-Trotsky regime is about to totter and fall. The following morning the newspaper tells us that quiet reigns in Moscow and that the government, if there be such a thing, has successfully quelled all revolution. We are told that Russia is on the road to industrial and agricultural recovery, and within the hour we read of the chaos into which all things have been plunged. We know not whither to turn for comfort or truth. Of two things, however, we can be reasonably certain: The revolution of 1917 was engineered by the Prussians, who deserve no country, and it was executed by the Jews, who actually have none. But whoever engineered it, and whoever executed it, we can rest assured that something worth-while will eventually emerge out of it. Just as France in the eighteenth century developed out of her chaos a new workable system so will Russia in the twentieth. And that which develops will be like nothing that we know; yet will it stand the test implied in the question “does it work”?

Italy too has been torn asunder. D'Annunzio, Trieste, and Fiume are ever-present causes of irritation. And the historical cities of northern Italy in which during the Dark and Middle Ages municipal independence was first realized, again, in another form, are expressing a desire for what is disguised as freedom. Is there nothing new in the world? In Germany *Der Tag* is secretly still the toast, more popular than before, and, who knows, more possible of realization. Belgium is on the road to economic recovery. But there are dark clouds ahead of her, for there is taking place a substitution of intensive corporate enterprise for individual endeavor.

The Determination of Zinc by the Potassium Ferrocyanide Method

By E. Olivier

*The determination of the zinc in Australian concentrate is usually carried out volumetrically, either by the so-called American method (the potassium ferrocyanide method) or by the Schaffner method (titration of the ammoniacal solution with sodium sulphide); this latter method is also sometimes termed the Vieille Montagne method. In the American method the ore or concentrate is decomposed by means of nitric acid and potassium chlorate, the mixture evaporated to dryness, the residue boiled with ammonia and ammonium chloride solution, and the filtrate acidified; the copper is removed by means of lead foil, the liquid is neutralized with ammonia, a

solution of potassium hydrogen tartate and ferric chloride is added, the solution heated to about 75°C., and titrated with standard potassium ferrocyanide solution in presence of ammonia until a spot-test with acetic acid shows a blue coloration.

The method used for preparing the solution for analysis results in the extraction of the zinc together with the copper, cadmium, calcium, and magnesium, and part of the lead, iron, and manganese. Of these elements only the zinc, copper, cadmium, and manganese are precipitated by the ferrocyanide, and only the copper is removed prior to the titration, so that the cadmium and manganese present are returned as zinc. Although the amount of cadmium present in the concentrate is usually so small as to be negligible (it averages about 0.1%), this is not so in the case of manganese, which may be present to the extent of considerably more than 1%, with the result that a high figure is returned for zinc. In one case, for example, I found 1.16% of manganese (as Mn_2O_4) in the zinc solution before titration.

That amounts of manganese such as are found in concentrate vitiate the titration is shown by experiments in which manganese corresponding to 2% and 4%, respectively, of Mn_2O_4 was added to solutions of known zinc content; on titration of these solutions 0.8% and 2.3% or zinc in excess of the quantity present was indicated.

To separate the manganese completely from the solution, a few cubic centimetres of hydrogen peroxide is added to the mixture of ammonium chloride solution and ammonia used to treat the residue resulting from the decomposition of the ore; this renders the manganese insoluble, and the results obtained agree closely with those found by the Schaffner method. When the percentage of manganese present is small (that is, 0.25%) the results obtained by the two methods (without the use of hydrogen peroxide) agree within about 0.1%, but in most cases manganese will be present in amounts sufficiently great to necessitate the use of hydrogen peroxide.

The American method has another disadvantage, especially where a large number of titrations have to be made daily: the titration is performed in hot solutions; this is necessary in order to obtain complete precipitation of the zinc ferrocyanide in a dense gelatinous form. Further, the blue coloration produced in the spot-test is not entirely satisfactory; the reaction is sensitive, but the color is not always distinctive in presence of colored ferrocyanides; the intensity of the color is not appreciably increased with increasing amounts of ferrocyanide.

In my opinion, the Schaffner method is preferable to the American method; the zinc precipitated as colorless sulphide, which affords a ready indication of its freedom from other metallic sulphides. The only other colorless insoluble sulphide known is the double sulphide of zinc and cadmium, discovered by me in 1886, but the error arising from this source is negligible because, as already pointed out, zinc ores contain very little cadmium; and, moreover, the greater part of the cadmium is separated as sulphide, together with the lead and copper.

REVIEW OF MINING

THE PERMANENT TARIFF BILL

The Fordney Tariff Bill introduced in the House on June 29 contains provisions for the following duties:

Barytes, crude \$4 per ton; ground \$7.50 per ton; precipitated barium sulphate or blanc fixe, 1c. per pound; lithopone and other combinations or mixtures of zinc sulphate and barium sulphate, 1½c. per pound.

Manganese ore and concentrates in excess of 30% metallic manganese 1c. per pound of metallic manganese content; ferro-manganese 2½c. per pound of metallic manganese content.

Molybdenum ore or concentrates 75c. per pound on the metallic molybdenum contained. Ferro-molybdenum, all molybdenum compounds and alloys, \$1.25 per pound of molybdenum contained plus 17% ad valorem.

Tungsten ore or concentrates 45c. per pound on metallic tungsten contained. Ferro-tungsten, tungsten powdered, all other compounds of tungsten, 72c. per pound on tungsten contained plus 15% ad valorem.

Bauxite \$1 per ton; aluminum 5c. per pound; in plates, sheets, bars, etc., 9c. per pound.

Magnesium \$1 per pound; magnesium alloys and manufactures \$1 per pound on magnesium content plus 20% ad valorem.

Quicksilver 7c. per pound.

Nickel in pigs 5c. per pound; manufactured 30% ad valorem.

Tin in bars or pigs, scrap or granulated, 2c. per pound.

Lead ores and mattes 1½c. per pound on lead contained, with a proviso for the admission of 2000 tons of lead contained in copper matte free of duty each year; lead bullion, antimonial lead, scrap-lead, type-metal, babbit, solder or alloys or combinations of lead, 2½c. per pound of lead contained; lead in sheets, pipe, shot, etc., 2½c. per pound; lead acetate, white, 3½c. per pound; brown, gray, or yellow, 2½c. per pound; nitrate 2½c. per pound; arsenate and resinate, 30% ad valorem; litharge, orange mineral, red and white lead 2½c. per pound; pigments containing lead 30% ad valorem.

Zinc-bearing ore, including calamine, under 10% zinc, free; over 10 and less than 20% zinc, ½c. per pound of zinc contained; over 20 and less than 25% zinc, 1c. per pound of zinc contained; over 25% zinc, 1½c. per pound on zinc contained for the next two years. Zinc in blocks, pigs, slabs, old and worn out zinc, 2c. per pound; in sheets, plates, strips, fabricated or zinc dust, 2½c. per pound. Thereafter duties shall be as follows: over 10 and less than 20% zinc, ½c. per pound of zinc contained; over 20 and less than 25% zinc, ¾c. per pound on zinc contained; over 25% zinc, 1c. per pound on zinc contained. Zinc in blocks or pigs and zinc dust, 1½c. per pound; in sheets, 1½c.; in sheets plated, 1½c.; old and worn-out zinc, 1 cent.

Graphite 10% ad valorem.

Fluorspar \$5 per ton for one year; thereafter, \$4 per ton. Kaolin \$2.50 per ton.

Antimony 1½c. per pound.

Mica 6c. per pound plus 17% ad valorem, unmanufactured 12c. per pound and 17%. Ground mica, 6c. per pound and 20% ad valorem.

Potash, for two years, 2½c. per pound on potassium oxide contained; one year thereafter 2c. per pound; one year thereafter 1½c. per pound; one year thereafter 1c. per pound; after five years, free.

Petroleum, crude, 35c. per barrel of 42 gallons; fuel-oil 25c. per barrel.

Magnesite, crude or ground, ½c. per pound; dead-burned and grained ¾c. per pound.

The Bill will be vigorously debated in the House, of course, and it is expected that it will come to a vote within two weeks. It is not expected that there will be any changes in the Bill on the floor of the House.

COPPER QUEEN ADOPTS PLAN FOR EMPLOYEES' REPRESENTATION

An employees' representation plan, unique in its liberality, has been adopted by the Copper Queen Branch of the Phelps Dodge Corporation at Bisbee. The plan is modeled after the constitution of the United States, and delegates in the fullest measure to the employees themselves, the regulation of the conditions of their employment. An idea of the radical trend of the plan may be seen in Sub-section 10, Sec. 9, Art. 1, which declares that the congress (of employees) shall have the power "To pass such measures as may be necessary for the peaceful settlement of all differences arising between the employees and the company". It is clear that under this provision the employees may regulate the hours of their employment as well as their pay.

The plan was drawn up by the Employees' Conference Committee, and submitted to the management for approval. It was approved by the board of directors and the management of the company, conditional upon its being adopted by a large majority vote of the employees of the company, at a special election held for that purpose. This election was held on June 28, and the plan adopted by the affirmative vote of 82% of the employees.

In adopting the plan the employees are taking a big burden of responsibility upon their own shoulders. In taking into their own hands the control of their relations with the company they will necessarily acquire a more intimate knowledge of the business and internal affairs of the company. Under Section 11 the question of closed or open shop is done away with by the declaration, "The right to work shall not be denied to anyone because of membership or non-membership in any organization, the principles of which are not in conflict with the Constitution and the Laws of the United States and the State of Arizona."

In returning the plan to the employees for their action, G. H. Dowell, general manager, said in part:

"The plan submitted for your approval and adoption is modeled after the Constitution of our own Country, under which every individual is given an opportunity for advancement according to his ability and determination, and every citizen is given a voice in making the laws that shall govern him. So it is to encourage the individual employee in advancement, and to give him a voice in making the rules that shall govern his conduct, that we favor the adoption of the proposed constitution. I have often said that the interest of the employee and his employer are the same, and that

neither can succeed unless both succeed. Under this proposed constitution I believe we may have a fuller measure of co-operation, greater success and more complete satisfaction in our work."

UNITED STATES SMELTING DECLARES DIVIDEND

Directors of the United States Smelting, Refining & Mining Co. have declared the regular quarterly dividend of \$7½c. (1½%) on the preferred stock payable July 15 to holders of record July 8. The consolidated earnings for the first five months of this year are estimated at \$872,497 after providing all interest. There have been deducted from these earnings reserves of \$435,882 for depreciation and depletion and \$131,065 for further exploration work in Mexico. These reserves aggregate in all \$566,947 and leave estimated net earnings for the five months of \$305,550, of which \$84,219 was earned in the first quarter. The preferred dividend requirements for the five months' period is \$709,260. The company's power supply in Mexico on which production depends has been substantially curtailed owing to a dry season. The rainy season now setting in will materially improve this condition. The demand for foreign silver has been sufficient to absorb the Mexican silver production and with any improvement of conditions in India and China increased earnings in Mexico may be hoped for.

MINERS STRIKE AT GRASS VALLEY

Failure of the operators of the Empire, North Star, and Idaho-Maryland mines and the Mine Workers' Protective League to agree upon a new wage-scale has halted virtually all mining in the district and 700 men are idle. The mines, however, are being kept unwatered. While George W. Starr, speaking for a group of operators, declared that negotiations would continue, William Southeutt, chairman of the scale committee of the workmen's league, stated that there was no immediate prospect of resumption and that the league had no proposals before it. The reduction of \$1 per day in the wage-scale announced on June 2 to become effective on July 1 would make the wage for miners \$4.62½ per day, while that for shovelers would be \$4.25. The operators stated in making the announcement that the mining problem in Grass Valley had resolved itself into a question of lower operating costs or abandonment of the mines.

The workers replied with a rejection of the proposed new scale and a criticism of the operators for making the announcement through the press before laying it before the miners' organization. A step in the direction of a settlement was started on June 19 when the workers proposed that the reduction be made 50c. per day instead of \$1 as at first intended. The operators replied that they could afford to pay only the scale originally announced and that the mines would close if the \$1 cut was not accepted. The old scale agreement expired on June 30 and the miners refused to go to work under the operators' intended scale.

SALE OF STANDARD MINE IS RATIFIED

The Standard mine, at Silverton, B. C., which contributed millions of dollars to its stockholders in the past, is to be sold for \$75,000. Negotiations for its sale were opened by the board of directors of the company several weeks ago and ratified by the stockholders at a recent meeting at Spokane. The property will pass to New York people under a bond and lease which must be exercised within 30 days. The identity of the purchasers has not been revealed. Their acquisition will include mining claims, mill, tramway, dock, and all other improvements. The transaction will leave the company without a mine, but with a surplus of \$250,000 to \$300,000. This money will not be disbursed, but will be retained for the purchase and development of

another property if it can be found. Several properties have been examined. "We sold the mine because we believed it was worked out," said an official. "The Standard was believed to have been worked out on three occasions, but as often new ore-shoots were uncovered by persistent operators. Its dividend yields aggregate \$2,700,000 made under the Finch & Campbell management, a sum that is raised to \$3,000,000 by the surplus."

DOLORES ESPERANZA CORPORATION RE-OPENS MEXICAN MINES

The properties of the Dolores Esperanza Corporation in Mexico, formerly owned by the Mines Company of America, which have been closed down for nearly eight years, are being re-opened. During the ten years from 1903 to 1913 the properties comprising Dolores Esperanza disbursed nearly \$5,000,000 in dividends. They were forced to close down in 1913. An effort was made to keep the mines open, but this proved very expensive, with the result that in 1918 the old company found itself not only with a depleted treasury, but in debt to the extent of \$500,000. The Dolores Esperanza Corporation was then formed to take over the properties. It has issued and outstanding 864,802 shares, par value \$2, which shares were underwritten at that price.

The Dolores mine, in Chihuahua, one of the group, has been unwatered, and development work is being carried on. Development work in the El Rayo is progressing satisfactorily.

The Dolores Esperanza Corporation now has approximately \$400,000 of cash or the equivalent thereto, and no debts.

SCALE OF OPERATIONS AT THE GARFIELD SMELTER IS INCREASED

The Garfield Smelting Co. has increased operations and is now smelting 500 tons of ore per day, as a result of working out a high-silica smelting charge. This has rendered it possible for a number of the Tintic properties to increase shipments of silicious silver ore, and also has enabled the Bingham Mines Co. and the Montana Bingham Mining Co. to find a market for their copper-iron sulphide fluxing ore. The silica content of the slag at the smelter is said to average about 48%, and this is believed to be the highest silica slag made by any smelter in the world. Before working out the new charge, the company made a slag averaging 40% silica. The Engels Copper Co. in California is shipping a high-grade concentrate, which, with scattered small shipments from various places, enables the company to operate two reverberatory furnaces and one converter.

SALES OF COPPER

The brisk business done by the Copper Export Association in the first five months of this year, fell off sharply during the latter part of June. In the period from January 1 to June 1 approximately 100,000,000 lb. of metal was sold for export at an average of 12½c. per pound, a large percentage of it being contracted for in May. Since then, however, business has dropped off. England and Germany have ceased to inquire for large amounts of copper; 1,000,000 lb. was sold recently for 13c. per pound for shipment to England, but this was the only sale in the million-pound column for some weeks. Domestic demand is the same as it has been—for small amounts and with no buyers contracting for future delivery. There are today only about four leading mines producing copper. Toward the latter part of July the American refineries will have worked off the metal now being treated and there will then remain only the South American mines and the quartette of domestic producers shipping to the Eastern reduction works. This outlook for reduced pro-

duction, however, has failed to influence domestic consumers. They cannot be stampeded into buying ahead of immediate wants, as they know today there is over 850,000,000 lb. of raw and refined copper above ground, of which over 600,000,000 lb. is ready for immediate delivery.

CALIFORNIA

Agua Caliente.—The Royal Flush property is owned by C. W. Chilson and J. O. Percival. Two ore-shoots outcrop at a distance of 120 ft. A tunnel tapping No. 2 ore-shoot at a depth of 55 ft. cut a 'pay-streak' averaging 7 in. wide. Samples taken assayed from \$81 to \$286. The latest development is a drift 20 ft. from the bottom of an 80-ft. winze; it discloses a full face of ore. The district has a good record for gold production.

Angels Camp.—The Victor Land & Mineral Co. is drifting for the west channel in its mine. At present work is in a good grade of gravel, below the rim. A new method of clean-up is being used, the material in the boxes being cleared of pebbles and light sand, the gold being left in the black sand, which is treated by amalgamation. The method

Jamestown.—The Eagle-Shawmut company is employing 23 men cleaning up and sinking its main shaft. The Ohio mine is erecting new houses for the staff.

Jackson.—The water in the Kennedy mine has been lowered to within 50 ft. of the bottom. This will not be pumped out at present. Extensive repairs are being made in the shaft-timbering, and the company hopes to be ready to produce regularly by August 1; 42 men are employed.

Melones.—The Patterson mine has contracted for a mill of 20-stamp capacity. This mine has been doing exploration work for the past two years and has developed a large block of ore which it is now proposed to mill.

Nevada City.—Pay-gravel has been found in the Penn-California mine in Willow valley, according to A. W. Hoge, the manager. The discovery was made in a raise recently driven about 100 ft. vertically. Hoge states that the gravel prospects well, but that through a miscalculation the channel was penetrated on the rim instead of near the centre as intended. The centre is supposed to be 40 or 50 ft. lower than the rim and to contain much richer gravel. Hoge says

The Old Anchor Tunnel at Park City, Utah

is quick, efficient, and cheap and removes all the gold and platinum. Cleaned black sand from previous clean-ups has yielded bullion in excess of \$4 per pound treated, in gold and platinum.

Bishop.—Operations have been resumed at Bishop Creek gold property under supervision of Gaylord Wilshire. The management states that as soon as the workings have been placed in shape for production, from 30 to 50 men will be employed. The property is well equipped and has yielded some excellent ore.

Downieville.—The Wisconsin Mining Co. has found gold-bearing gravel on the old Parkman ground. Work done so far indicates a large deposit of profitable gravel.

Forest.—E. H. Graham, of Grass Valley, has brought 10 millwrights to begin the erection of the 10-stamp mill of the Kate Hardy Mining Co. and to erect other buildings. The ore-bins at the mine are full and development work is progressing satisfactorily.

Glencoe.—A discovery is reported at Glencoe on the Stoetzer ranch, by A. J. Bayless. The vein is reported to be 18 in. wide, the ore assaying from 5 to 10 oz. in gold.

Grass Valley.—A raise from the 400-ft. level of the Alcalde mine has been started. This raise, which will reach the surface, together with a winze sunk at the same point, will form a vertical shaft to replace the old incline.

that in addition to the two miles of channel owned by the company, two promising lodes have been cut. A drift will be run on one of these to get directly beneath the gravel channel.

Quincy.—The first clean-up at the Australia placer mine was made last week; 41.56 oz. of gold was obtained. This does not come up to expectations, but considerable dead work in the building of flumes, ditches, and boxes has been completed and the company is very optimistic about the future results. The mine is situated about 12 miles from Quincy on the old Erickson claims.

The Mason Valley smelter interests are developing their property, leased from J. E. Murphy and R. Barnes and situated about eight miles from Genesee. They are drifting on the ore and have already completed about 125 ft. of the tunnel. It is planned to cross-cut both ways at a distance of 150 ft. from the portal. Chris Smith is superintendent in charge of the property.

Scales.—Preparations are being made by H. L. Berkey for making a final clean-up from his hydraulic operations near here that were begun last November.

COLORADO

Boulder.—An important find has been made on the Bluebird mine of the North Boulder Creek Mines Co., in the Caribou district. A vertical vein in contact with a strong

porphyry dike has been opened, that samples as high as 425 oz. silver per ton. in the Santa La Saria tunnel. The company's 50-ton flotation mill is reported operating steadily and, concentrating 30 to 1, is saving better than 90% of the silver-lead content of the ore. Eastern capitalists are interested.—Lessees on the Caribou continue mining a good grade of ore. Chicago men have become interested in a lease on this property and the extension of the present tunnel, now in 6000 ft., is planned.

Breckenridge.—Placer production in Summit county promises to increase as operations are being extended to properties not worked since before the War. The Washington placer is active and one 'giant' is tearing down the high bar for Charles Siessler and son. The Carpenter placer at the head of Nigger Gulch will be prospected and the Tonopah Placers Co. has its big dredge operating. Other dredges are being put in condition for the season's work.—Seepage water from melting snows has temporarily stopped operations at the 300-ft. level of the 'Deep Shaft' by the Tymes company, and a pump has been ordered. The Tymes was cross-cutting to cut the Brooks-Snyder and Ground Hog veins believed to extend across Tymes territory.—The Royal Tiger Mines Co. is maintaining operations at full capacity under John A. Traylor, manager. Lead carbonate ore containing gold and silver is being shipped to the A. V. smelter at Leadville by lessees of the Price, Standard, and Missouri lode properties.

Central City.—A committee of the Metal Mining Association of Gilpin county is working to secure a sampling plant for this district. Sufficient funds seem to be assured for the erection of a plant. Returns from a 20-ton shipment from the Frontenac mine gave \$85 per ton in gold, silver, and copper. Lessees are opening stoping ground and will shortly increase production.—The Midwest M. & M. Co. is mining a good grade of ore from two parallel veins in the Cyclops tunnel workings in the Hughesville district.

Cripple Creek.—Operations have been resumed by the War Eagle Consolidated Mines Co. from the 1100-ft. level of the Blue Flag-Silverton shaft. A contract has been let for extension of the lateral to a point directly under the Scott or main shaft, when connection will be made by raising. The Moffat tunnel, connecting with the Blue Flag workings, is to be extended north-east through the Sheriff, thence to the Amanda and War Eagle. A cross-cut will also be carried from the Blue Flag through the Bogart and Happy Year holdings of the War Eagle company. Tully Scott of the Colorado Supreme Court is president of the War Eagle company.

Lessee Fish of the Vindicator Consolidated, operating a block of the Golden Cycle mine, extending from 600-ft. level to the surface operating through the Longfellow shaft on the Stratton estate, has opened what is believed to be the south-western extension of the rich Hayes ore-shoot. A drift has been carried about 50 ft. on a good grade of ore, with rich seams of sylvanite in four to six feet of vein matter. The ground to the surface is virgin and the lease, should the shoot extend upward, will be a fortune-builder.

Idaho Springs.—High-grade silver-lead ore assaying as high as 200 oz. silver and 45% lead has been opened in a vein 2½ to 5½ ft. wide on the property of the Blue Ridge Mining Co., in the Montana mining district, south-west of Dumont in Clear Creek county. The ore was cut by the Upper West tunnel. The company is also developing its Happy Thought and Albro Hill groups, in the Morris and Fownleville mining districts, by extension of the Hlawatha tunnel, now in 1100 feet.

Leadville.—The Best Friend mine in the Big Evans gulch section, inactive for the past 10 years, has been leased by local operators who plan to extend the 2000-ft. tunnel to prospect unexplored territory.—The Long & Derry mine,

an old Iowa Gulch producer, has been leased for a long term to James McMullen, who recently returned from Montana.—The Fidelity Mines Co. has resumed operations in the Twin Lakes district. The property, situated on a spur of Mt. Elbert, is producing ore from a three-foot vein assaying \$87 per ton in gold with about five feet of \$7 mill-ore in addition.

Silverton.—The Gnome Mining Co. has a crew engaged to resume development on its properties near Animas Forks.—The Highland Mary mine in Cunningham gulch, has been leased to local operators and shipments will soon be resumed from the property.—The mill and tramway at the Liberty Bell mine are again operating to clean-up and treat a big block of ore "found sealed up" after the mine was closed-down last April. Power is furnished from the Deer Trail pipe-line and the mill will be kept in operation until the ore is exhausted.

IDAHO

Bonner County.—The Carpie Mining Co., owning a copper property at Cabinet, is installing a new hoist and compressor, and will sink the shaft from the 300-ft. level to 1000 ft. The vein on the 300-ft. level is said to be six feet wide in the face of the drift.—A 10-in. vein of silver-lead-copper ore averaging \$105 is reported by W. M. Hollenback, of the Falls Creek Mining Co. on Pend Oreille lake. This company has a 50-ton concentrator, a water-power plant, and other equipment; it intends to add flotation to save the silver.—A streak on the surface of the American Eagle Mining Co.'s property returned 112 oz. in silver and 48% lead. The values come from a contact vein along a dike about 100 ft. wide. The vein is from two to eight feet wide. About 1400 ft. of development work has been done.

From the Bluebird mine lessees are shipping gray copper ore that is said to run from 400 to 1500 oz. in silver. A small carload was shipped two months ago; another is being loaded. The Bluebird adjoins the Armstead mine.—At Clarks Fork a long tunnel is being driven by contract on the property of the Clarinda Copper Mining Co.—Spokane people are largely interested in the Lawrence Mining & Milling Co. at Clarks Fork. The company's lead ore is said to be rich. Joseph Reed is manager.—At Hope a small force is working the property of the Hope Mining & Milling Co. Copper, silver, and lead are contained in the ore.

Coeur d'Alene.—A drift on the deep level of the West Hunter mine at Mullan lacks 200 ft. of a point where it will under-cut the shoot showing on the surface, according to Edward T. Davy, president. A vertical depth of 1000 ft. will be attained. A distance of 850 ft. has been driven from the American Commander tunnel through which entrance to the West Hunter is obtained.

Three feet of high-grade ore, said to be the best yet found in the property, was opened recently by lessees in the lower workings of the Western Union Mining Co. It is expected to assay well in silver. These lessees are loading another 50-ton car for shipment to the smelter. Other shipments have averaged 50% lead and 44 oz. silver.

Moscow.—Although there are not more than a half-dozen heavy producers in Shoshone county, which includes the Coeur d'Alene, the Government report shows that 39 properties, large and small, contributed to the total tonnage in 1920. Idaho county had 18 small producers; Clearwater, 5; Bonner, 3; Latah and Benewah, 2 each; and Boundary, 1. The one in Boundary was the Idaho-Continental, which had an output during the year of \$348,138 more than the production of all other counties of northern Idaho combined, except Shoshone county.

KANSAS

Baxter Springs.—Mining operations in this district are getting in shape to be able to take advantage of any improvement in the ore market by sinking shafts and putting

their present properties in condition where they can be run at capacity when the market improves. O. M. Billharz and associates are sinking a shaft on the property situated about a mile west of this city on the Chetopa road, known as the Hartley homestead. The derrick has been erected, work on the hole is progressing rapidly. This is the property on which a sensational find was made a few weeks ago.—The erection of a big mill on the Brewster land, just west of the Hartley homestead, is well under way. This is being built by the Chanute Smelter Co. The same company is making preparations to erect a mill on the Karl Ebenstein land, which adjoins the Brewster claim.—The Rakowsky-Billharz people also will have a mill on the W. T. Hartley property, just west of the R. F. Hartley mill and J. H. Goodwin and associates have everything ready for a mill on the race-track grounds.

MICHIGAN

Houghton.—Equalization valuations of the Lake Superior copper mines, which are based on the market values of the respective shares, show an average reduction this year of 30%. These have been determined in other years in October, but under a new Michigan law will be fixed in June hereafter.

The total equalized valuation for Houghton county, the greater part of which is in mining property, is \$64,081,653 as compared with \$91,878,050 last year. Calumet township, in which Calumet & Hecla is located, shows a reduction of nearly \$10,000,000; Adams township, which includes the Copper Range mines, is reduced \$7,500,000; Quincy, \$1,000,000; Franklin, \$1,000,000; Osceola, \$2,000,000; and Portage, in which is located Isle Royale, \$2,000,000. Keweenaw county's equalization values have been fixed at \$16,000,000, which compares with \$21,000,000 last year. The greatest reduction was made in Allouez township in which the Ahmeek and Mohawk mines are located. The tax rates will not be set until fall. It is known they will be higher than last year but the mining companies still will benefit somewhat as a result of the reduced valuations.

With the exception of a few small orders for domestic delivery, there is little inquiry for metal and there have been no shipments out of the district in the past week. While Mohawk and Wolverine continue to produce at capacity, sending a total of 3500 tons of rock to the mill daily, Copper Range is still on a 60% basis and Quincy is barely keeping open with production one-third that of normal years. Calumet & Hecla is operating only 5 of its 24 furnaces. It has only a small quantity of mineral on hand at the smelters and only enough cupola blocks to keep the plant in operation another month. When this supply is exhausted there will be no necessity for continuing unless special orders for metal are received in the meantime. The smelters are turning out anodes from cupola blocks and cathodes that are returned from the electrolytic plant are either smelted into bars or ingots or held in reserve for remelting into special shapes.

It is unlikely that the reclamation plant, to be built on the Tamarack conglomerate sands by Calumet & Hecla, will be started this summer although steel and other material, ordered before the depression in the industry set in, has been arriving at the site. There are 12,000,000 tons of sand in the Tamarack deposit, carrying from 10 to 12 lb. of copper to the ton, which was laid down in Torch Lake at a time when milling processes were not perfected to the extent they are today and the losses were comparatively large. This copper can be recovered at a cost of not more than seven cents per pound, exclusive of smelting and selling costs.

MISSOURI

Joplin.—A semi-official survey of the Tri-State zinc and lead district reveals the fact that more than 40 mines have been operating on full time and several others on part time.

In addition to this several mills are treating tailing. This is a larger number than had been currently reported but this is believed to have been due to the fact that several milling concerns are operating two plants each and that the first survey had reference to the number of companies in operation. Some of the plants are expected to close down this week.

NEVADA

Goldfield.—The Silver Pick has started stoping the ore opened recently in the lease of that company on the Red Top of the Consolidated. This ore was found 100 ft. into the foot-wall of the vein, at a depth of 265 ft. It is in entirely unexplored territory. The vein lies rather flat and apparently has a general strike north-west from the main ore-channel. A width of 10 to 20 in. on the hanging wall assays \$150 to \$800, but the ore as broken for shipment, from about half the drift, assays \$50 to \$150. The shoot has

The Telluride District in Colorado

been opened for a length of between 40 and 45 ft., without the end being reached and work has been started to explore for it on the 365-ft. level. This work is being done less than 100 ft. from the Red Top shaft, but as the machinery has been removed from this shaft, hoisting is done through the Laguna shaft, which is well equipped. Because of the position of the ore far into the foot-wall and the strike of the vein the find is regarded as the most important made in the district in recent years.—Donald and Gilles, lessees on the Florence, have exposed for a length of 18 ft. the rich ore found by them in the hanging wall of the old Reilly flat stope at a point 40 ft. above the 160-ft. level, and they have started stoping. The ore being broken for shipment in bulk assays \$300 to \$400. The first 10 tons of this ore assayed \$360. The rich widths on the foot and hanging wall continue and the gouge between is increasing in value. It is possible for the ore to have a length of 70 ft. and to extend to the surface. The stope in which this ore was found caved in the early days and had not been entered from then until Donald and Gilles raised more than 50 ft. into the foot-wall.

The shaft of the Deep Mines is 650 ft. deep. At 515 ft. it passed from the andesite into the latite and, except that the C. O. D. and Victor veins should be cut before the 1000-ft. level is reached, no further change is anticipated. The main vein system is at 2400 ft., in the latite near the latite-

shale contact. The shaft is 5 by 17 ft. in the clear and it consists of three compartments, two 4½ by 5 ft. for hoisting and one, 5 by 7 ft., for the pipes, electric cable, and ladders. The ventilating-pipe, 2 ft. in diameter, extends to the top of the head-frame and a suction ample to ensure good air at the bottom of the shaft is obtained by the natural heating of the upper length by the sun. Three stations will be established, at 800, 1600, and at 2400 ft. The water from the bottom will be pumped to the surface in three lifts, 2400 to 1600, 1600 to 800, and 800 to the surface.

Silverhorn.—Dan Foley has opened ore in several new places in the vein he recently discovered in the south-eastern end of the district and he reports assays ranging from \$11 to \$743 per ton. New work was started during the week on the Silver Carlisle group, located east of the Silver Peer and controlled by New York men. Robert Mulford, Frederick G. Corning, C. V. R. Cogswell, and Sidney Green, all of New York, are directors with Theo. Crampton, managing director at the mine.—In the north cross-cut on the 50-ft. level of the Huson shaft on the Silver Dale the lode was 10 ft. wide at last reports and assayed from \$12 to \$30 per ton.

Tonopah.—The Belmont company's mill, the largest reduction plant at Tonopah, has resumed operations on a 50% capacity schedule. This is the first time the Belmont mill has turned a wheel since the mine strike was declared nearly two months ago. The Tonopah Extension's mill has been in operation for a fortnight. It also is running on a reduced schedule, but the mine owners expect to increase operations as the importation of new men into the camp continues.

It is said that the Belmont now is employing 170 men and over 100 men are at work at the Extension. These are the two largest properties in the Nye County camp.

No attempted disturbances have been reported since the arrival of the State police and the authorities expect no further difficulties.

UTAH

Alta.—Ore shipments from this district are averaging about 150 tons per day. Shipments are coming principally from the Columbus-Rexall and the South Hecla properties, each of which will average 50 tons per day within the near future. The Michigan-Utah mine is now making shipments. A new cable has been installed on the tramway from the mine to Tanners' Flat, and a spur of the Little Cottonwood railroad has been built to the ore-bins at the tram-terminal to avoid hauling by team. At the Sells property four or five carloads of ore are ready for shipment.

Bingham.—Twenty miners have been added to the working force at the Bingham-Galena property, formerly known as the Silver Shield, according to H. S. Joseph, a director of the company. Shipments are being made to the United States smelter at Midvale, averaging \$2 in gold, 10 oz. in silver, and 15% lead. The ore is coming from the Bully Boy group. Eugene Grutt has been appointed general superintendent of the mine, under O. F. Brinton, consulting engineer.

Delta.—R. H. Evans and associates have resumed work at the Purdy-Evans mine in the Sawtooth mountains, about 50 miles south-west of this city. Development work was begun in April, but owing to a dispute with A. B. Knowlton, who claimed to have prior rights, the question of ownership was investigated and Evans and associates were found to be the lawful owners. Development was started on the Last Chance No. 1, 2, and 3 claims. A body of molybdenum ore was opened which assays from 15 to 19%.

A large deposit of strontium carbonate ore has recently been discovered in this vicinity by F. L. Byron and Daniel Potter. It is stated that the deposit has been opened for a distance of nearly a mile, with a width of 600 ft. and a

depth of about 200 ft. It occurs in two forms; one hard and crystalline, and the other fibrous and soft.

Eureka.—During June, approximately 150 men were added to the working forces of local mines, with the result that there is practically no unemployment of miners in this district. The greater part of this number has been employed at the Tintic Standard and Eagle & Blue Bell properties.

Output of ore from this district is increasing, owing to several of the mines having received permission to ship silicious silver ore to Salt Lake valley smelters. During the week ending June 25, the Tintic Standard shipped 46 cars; Chief Consolidated, 42; Iron Blossom, 14; Eagle & Blue Bell, 12; Dragon, 8; Iron King, 7; Victoria, 5; Gold Chain, 4; Swansea, 3; Gemini, 2; Eureka Bullion, 1; Mammoth, 1; making a total of 145 carloads, the heaviest in many weeks.

A shipment of ore from the Eureka Bullion mine during the latter part of June averaged 25 oz. silver and 15% lead. This is the best ore yet found at that property, according to J. M. Bestmeyer, manager.

At a meeting of the directors of the Chief Consolidated Mining Co. on June 30, a dividend of 5c. per share was declared, payable August 1. This is the third dividend to be paid this year and will aggregate \$44,201, bringing the grand total up to \$2,004,122.

Frisco.—Regular shipments are being made from the Quad Metals mine, according to Grant H. Snyder, manager. This ore, a high-grade silver-lead sulphide, is being mined on the 700-ft. level. Smelter returns on two carloads shipped recently netted the company \$1700 and \$2800.

Park City.—The largest output of ore in many weeks was made by local mines during the week ending June 25, when 1755 tons were shipped. Shipments are being increased by the Silver King Coalition, and the Naildriver property has again become a shipper. The Silver King Coalition shipped 661 tons; Judge companies, 579; Ontario, 335; and Naildriver, 180. Shipments during the previous week totaled 887 tons.

Salt Lake City.—The assessed valuation of metal and coal-mining property in Utah for 1921 is \$64,232,112, as compared with \$61,598,942 for 1920. Salt Lake county, in which is situated the Utah Copper property, heads the list with a valuation of \$32,254,757, or slightly over one-half of the grand total. The State constitution requires that all mining property shall be assessed by the State Board of Equalization; that metalliferous mines shall be assessed at three times their net proceeds for the preceding year, plus the value of real estate at \$5 per acre, plus the actual cash value of machinery, mine buildings, and other surface improvements. Non-metalliferous mines are assessed by the State Board at a valuation to be determined by it from a study of the probable deposits.

The annual meeting of the Rocky Mountain Coal Mining Institute was held in this city on June 28 and 29. Four States were represented—Colorado, Wyoming, New Mexico, and Utah. The coal-men attending the convention represented mining companies which produce annually about 40,000,000 tons of coal. One of the features of the meeting was the reading of a paper by A. C. Watts of the Utah Fuel Co. on 'Fighting Mine Fires'.

Tooele.—The International smelter suspended operations entirely on July 1, for an indefinite period. The copper department of the plant was closed down last autumn, but for the past few months two of the five silver-lead blast-furnaces have been operated. Lack of ore was given as the reason for the closing. About 300 men will be thrown out of employment as a result of the shut-down.

SOUTH DAKOTA

Lead.—The Homestake Mining Co. has issued a second dividend of 25c. per share. The first dividend since March

1919 was declared on May 25; the latest, on June 25. Decreased operating costs resulting from lower wages and lower prices of supplies, together with increased efficiency of mine labor, have made the resumption of dividends possible.

BRITISH COLUMBIA

Greenwood.—The first shipment of the year from the Providence mine has been made to the Trail smelter. Between 35 and 40 men are employed at the mine, and from now on it is expected that weekly shipments will be made. The ore contains gold, silver, and lead; 338 tons that was shipped in 1919 yielded 267 oz. gold, 38,903 oz. silver, and 7616 lb. of lead. Treatment charges and freight cost about \$11 per ton.

Kaslo.—A. J. Curle has uncovered a promising new vein on the Kirby property. The vein is well mineralized and ranges from 25 to 35 ft. in width. Last year Curle discovered a 13-ft. vein on this property, assays from which have run from 25 to 2000 oz. in silver; the vein is being developed by a shaft. The property adjoins the Bluebell mine, which shipped steadily to Trail last year.

Princeton.—Bert Powell has bought the Condit brothers interests in the Horn Silver mine, in the lower Similkameen valley, and now is sole owner of the property. Several shipments have been made from the mine this year, but Powell now purposes to try to interest capital for the purpose of erecting a small reduction plant at the mine.—The Tulameen Mines Operation Co. is getting out lumber for the erection of a flume at Bear creek, where the company purposes to operate placer deposits for the recovery of gold and platinum. The best specimens of placer platinum that have been found in British Columbia have come from tributaries of the Tulameen river.

Stewart.—The Linderbourg brothers, of Hyder, have started to develop their property at Seven-mile, where there is a large body of medium-grade ore. A tunnel that has been driven for 340 ft. is to be extended.—The Fish Creek Mining Co. has re-started the development of its property on Fish creek, on the Alaskan side of the international boundary.

MEXICO

Torreón.—La Pluma, a group of ten silver-lead mines, situated in the San Lorenzo mountains near Matamoros, has been taken up by Jesus Rodulfo and associates, of San Pedro. Development work is being carried on. Several other promising properties are being filed on in this district.

Durango.—Gen. Enrique R. Najera recently located a group of seven pertenencias in the Avino district. The claims adjoin the Socavon, Bolso, and Cuatro Amigo mines. General Najera acts as Governor of the State when Governor Agustín Castro is absent. He has extensive land and mining interests throughout the State.—The old Cedro mines in the Escobar district have been re-located by Abdon Alanís of Tepehuanes and will be patented under the title of San Luis. These properties are producers of gold and silver and were recently declared forfeited for non-payment of taxes.

Guanacevi.—Herald McLeod Cobb is exploring the San Valentine mine in La Luz mountains. This property lies contiguous to the old Veta de Oro mine which has produced an abundance of rich ore.—The old Ofelia group of mines in the neighborhood of La Violeta and Veta Grande groups has been filed on by Charles Suayfeta.—Another recent filing in this district has been made by Manuel Bolívar, who has applied for titles to a group of three claims to be titled under the name of Cabadena. It is situated near the San Francisco and Isaura mines, which are gold, silver, and lead producers.

ONTARIO

Elk Lake.—The hematite iron deposit recently discovered in Morel and Yarrow townships, is being explored by the owners, and it is stated that the result points to a large body of ore. Another outcrop of high grade hematite is stated to have been discovered in the vicinity. These discoveries have stimulated prospecting and a large number are engaged in the work.

Kirkland Lake.—Much new capital is seeking investment in this field, where many mining engineers representing important interests are making investigation.—The White-Kirkland Gold Mining Co., capitalized at \$500,000, in which Cleveland, Ohio, men are interested, has secured a property of 130 acres and will shortly begin development.—The Lebel Lode, Ltd., has been incorporated with a capital of \$2,000,000, to develop three claims aggregating 100 acres north of the Lebel Oro and the King Kirkland, on which veins have been found showing good gold content on the surface.—The Wood-Kirkland has a force of men engaged in surface work. A plant will be installed before winter for underground operations.—The Ontario Kirkland has placed an order for electrical equipment for their mill to cost \$22,000.—The Lake Shore during May produced gold to the amount of \$29,637 from the treatment of 1865 tons of ore, being an average recovery of \$15.88 per ton. Harry Oakes, the president, states that the matter of enlarging the mill has for the present been left in abeyance.

Larder Lake.—A Toronto syndicate headed by S. J. Thomas has taken up options on seventeen claims and has eleven more under options. The plans of the syndicate are to some extent dependent upon the construction of the projected light railway.

Porcupine.—Owing to the increased activity in gold mining, the town of Timmins is overcrowded with people who are unable to find house accommodation and are obliged to find shelter under canvas. The present building program appears inadequate to meet the requirements of the coming winter. A scheme for the formation of a company to build a number of small houses for sale is under consideration.—The McIntyre will close one of the most prosperous years in its history on June 30. It is understood that the annual statement will show profits in the neighborhood of \$1,000,000 before providing for depreciation, and that the grade of the ore has been well maintained at around \$11 per ton.—Preliminary work is being done on the Big Dyke, formerly the McRae Porcupine. The company has secured an option on the Pike Lake property adjoining.

South Lorrain.—The mill of the Keeley has been put into operation and good results are officially reported. A good concentrate is being produced at the rate of 1½ tons per day and a substantial amount of high-grade is being cobbled for shipment.

West Shining Tree.—The Wasapika Consolidated has a large amount of high-grade ore in sight. The vein has a width of 25 ft. on the 200-ft. level and there is much ore that can be worked from open-cuts. The management has decided to proceed immediately with the construction of the first 50-ton unit of a 200-ton mill.

QUEENSLAND

Cloncurry.—An important deposit of cobalt ore is being worked 20 miles south of Selwyn. Four shafts have been sunk on the lode, to depths varying from 20 to 112 ft. The lode, as exposed, is 4 to 5 ft. thick, and extends along the surface for upward of 300 ft. The assay is about 6% cobalt, with no other valuable metals. A trial shipment of 50 tons of ore has been sent to England. A small crushing and concentrating plant is to be erected.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

P. B. McDonald is in London.

Howard D. Smith is here from New York.

J. Parke Channing recently visited Miami, Arizona.

Galen H. Clevenger has returned to Boston from Mexico.

Lyman F. Barber is at Los Angeles, where he will spend the summer.

James S. Douglas has returned from France and is now at Jerome, Arizona.

W. H. Blackburn, of the Tonopah Mining Co., is in San Francisco for a week.

W. V. Griffith has moved from Christmas, Arizona, to Geyserville, California.

E. J. Franklin, mechanical engineer for the Ray Consolidated Copper Co., is at Chicago.

R. L. Beals is general superintendent for the Shasta Zinc & Copper Co., at Bully Hill, California.

Samuel W. Traylor was married to Miss Lottie Greenwood Lakel on June 24, at Allentown, Pennsylvania.

Edwin Higgins has gone to Telluride, Colorado. He will visit Michigan before returning to San Francisco.

John V. Richards is in eastern Oregon for the summer, in charge of a field party of the Oregon Bureau of Mines.

Edgar N. Rhodes has been appointed president and general manager of the British America Nickel Corporation.

Charles Bocking, manager for the Butte & Superior Mining Co., has returned to Butte after a trip to Eastern cities.

William T. MacDonald, mill superintendent for the Moctezuma Copper Co., at Nacozari, Mexico, is at Salt Lake City.

R. E. Howe and A. D. Wilkinson, of the Greene Cananea Copper Co., Sonora, Mexico, were in San Francisco recently.

H. Steele has gone to Mexico City to take charge of the enterprises of the American Metal Co., Ltd., in that country.

Brent N. Rickard, assistant superintendent of the A. S. & R. smelter, at Murray, Utah, is on a vacation at Fish Lake, Utah.

J. C. Kinnear, smelter superintendent for the Nevada Consolidated Copper Co., was in San Francisco on his way from Los Angeles.

Stuart G. Taylor, treasurer for the Judge mining interests at Park City, Utah, has returned to Salt Lake City after a vacation in Los Angeles.

Alan M. Bateman has gone to Alaska to report upon the exploration and development of the properties of the Kennecott Copper Corporation.

J. B. Jensen, mining engineer of Salt Lake City, is making an examination of shale deposits for the Standard Shale Products Co., near De Beque, Colorado.

G. F. Williamson has resigned from the position of superintendent of the Blue Mountain gold mine in Kern county, California, and is now at Amador City.

F. C. Calkins, geologist of the U. S. Geological Survey, is in the Big Cottonwood mining district, Utah, completing a survey that was started some years ago.

George S. Rice, of the U. S. Bureau of Mines, passed through San Francisco on his way to Alaska, where he will make a study of the Matanuska coalfield.

Roy H. Elliott was staying at the Ohio House, at Placerville, when it was burned on June 26, and narrowly escaped, suffering some burns, fortunately not serious.

R. C. Gemmell has been elected a director of the Nevada Consolidated Copper Co., and Louis S. Cates a director of the Utah Copper Co., these engineers respectively replacing William Potter, who has resigned.

Obituary

Arthur Kinney Adams died on November 2, 1920. He was born in Worcester, Massachusetts, on July 9, 1883, and attended the four-year course in general science at the English High School there from 1896 to 1900. He then spent three years at the Worcester Polytechnic Institute, from 1900 to 1903, combining the chemical and mechanical engineering courses. In the autumn of 1903 he entered Lawrence Scientific School, where he specialized in geology, receiving the degree of B. S. in 1904. The summer of 1904 was spent at the Harvard Engineering Camp, in field work in surveying. That autumn he returned to Harvard University, to the Graduate School of Arts and Sciences, studying advanced geology, especially applied geology, and acting as laboratory and field assistant in geology. There he received the degree of A.M. in 1905. In June of 1905 he was appointed field assistant in the U. S. Geological Survey, and spent the summer in topographic and geologic mapping of a coal- and oil-field in north-west Pennsylvania. Between 1905 and 1906 he spent half a year in studying mining, milling, and economic geology at the Massachusetts Institute of Technology while he was acting as laboratory and field assistant in mineralogy, lithology, field geology, and advanced field geology. In 1906, again as field assistant for the Geological Survey, he did further topographic and geologic mapping in Oregon and Colorado, later returning East to travel from Maryland to Alabama sampling and inspecting bituminous coal and mines in the Appalachian mountains. From 1907 to 1909 he taught in the New Mexico School of Mines at Socorro, New Mexico, as professor of geology and mineralogy. From 1909 to 1912 he was again in the government service, this time in the U. S. General Land Office as Mineral Land Inspector. As geologist and assistant mining engineer for the Socorro Mining & Milling Co., of Mogollon, New Mexico, he spent the better part of 1912-'13. He worked during the summer of 1914 in the smelter at El Paso, Texas. Further teaching followed in 1914-'15 at the Texas School of Mines, Fort Bliss, Texas, where he was professor of geology and coal mining. Between 1915 and 1916 he studied mining and milling methods in the Southwest, especially with regard to the flotation of copper, silver-lead, and zinc ores. In 1916 he left for foreign work, entering the employ of the Andes Copper Mining Co. After eighteen months in Chile he returned to enter the U. S. Army. In July of 1918 he received a commission as 1st Lieutenant of Engineers, U. S. A.; and in August entered the Engineer Officers Training School at Camp A. A. Humphreys, Virginia. In October, after only two months as a student officer, he was appointed 1st Lieutenant in the Second Engineer Training Regiment. Two weeks previous to his discharge from the Army, in April 1919, he was appointed Instructor in Mineralogy and Senior Instructor in Geology at the Engineer School at Camp Humphreys. After his discharge from the Army, on May 1, 1919, he sailed from New York for a trip to Bolivia as geological engineer for the Guggenheim Brothers. In January 1920 he entered the employ of the Sinclair Consolidated Oil Corporation of New York. In February he proceeded to San José, Costa Rica, in charge of surveying the boundary line of a concession granted them by the Costa Rican government. His health was already affected as a result of work at an altitude in Bolivia. In July he contracted malaria; late in October he suffered a second attack, which occurred after he had returned from the field to his home in San José, where he died. He was twice married—in December 1909 to Helen Terry, of Socorro, New Mexico, whose death occurred five years later in El Paso, Texas; and in December 1919 to Dorothy Cobb, of Falls Church, Virginia.

THE METAL MARKET

METAL PRICES

San Francisco, July 5

Aluminum dust, cents per pound	75
Antimony, cents per pound	4
Copper, electrolytic, cents per pound	13.00—13.25
Lead, pig, cents per pound	4.65—5.65
Platinum, pure, per ounce	\$75
Platinum, 10% iridium, per ounce	\$95
Quicksilver, per flask of 75 lb.	\$18
Spelter, cents per pound	6.50
Zinc dust, cents per pound	9.00—9.50

EASTERN METAL MARKET

(By wire from New York)

July 4.—Copper is inactive and soft. Lead is quiet but firm. Zinc is dull, but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 40.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

STATISTICS ON GOLD

Gold imports into the United States in the fiscal year just ended aggregate, in round terms, \$650,000,000, or more than in any year except 1917, when they aggregated \$977,000,000, says a statement by the National City Bank. Of course, adds the bank's statement, not all of the \$2,630,000,000 of gold imported since the beginning of the War has remained with us, for the gold exports in the same period (1914-1921) aggregated \$1,135,000,000 leaving the net imports (in excess of exports) for the entire period of 1914-1921 \$1,500,000,000, while the \$530,000,000 turned out by our mines during that period brings the total additions to our gold stock since 1914, by importation and domestic production, up to \$1,725,000,000, of which, however, nearly \$300,000,000 has been used for industrial and scientific purposes, leaving the net additions, since 1914, to our gold available for currency purposes about \$1,350,000,000. It is not surprising then that the Circulation Statement of the Treasury Department shows the total stock of gold in the United States on June 1, 1921, as \$3,175,000,000, against \$1,892,000,000 at the beginning of the War.

What has the remainder of the world done about gold for monetary purposes meantime? The Reports of the Director of the Mint showing the "approximate stocks of money in the principal countries of the world" put the total of gold for all countries for which statistics were available at \$8,240,000,000 at the beginning of 1914 and \$8,340,000,000 at the beginning of 1919, though the 1919 tabulation fails to include figures for certain countries which are known to have been at that time about \$500,000,000, suggesting that the total of world's gold stock at the present time is nearly \$9,000,000,000, though only a small proportion of this is in actual circulation, most of it being held in banks and public treasuries as a basis for the enormous paper circulation.

This world total of approximately \$9,000,000,000 of gold stock available for currency seems to add weight to the often expressed belief that only about one-half of the world's gold production passes into coin or becomes a basis for currency, since the known figures of gold production from the discovery of America to the present time show a grand aggregate of \$18,000,000,000, of which total about one-half is now recorded as in existence, either in the form of coin or as a basis for circulation. Curiously, too, about one-half of this enormous total of \$18,000,000,000 produced by the mines of the world has been turned out since the famous gold versus silver campaign of 1896, since the records of world gold production show the total output from 1896 to 1921 at \$9,335,000,000 out of a grand total of \$18,115,000,000 from 1492 to 1921.

The share of the United States in the existing gold 'monetary stock' of the world has advanced from about 22% prior to the War to approximately 37% at the present time, though this figure as to present conditions can only be a rough approximation owing to the difficulties of obtaining late figures for certain countries under the now existing conditions.

MONEY AND EXCHANGE

Foreign quotations on July 5 are as follows:

Sterling, dollars:	Cable	3 74 1/2
	Demand	3 73 1/2
Francs, cents:	Cable	8.11
	Demand	8.09
Lire, cents:	Demand	4.95
Marks, cents		1.39

Eastern Metal Market

New York, June 29.

The approaching holidays incident to Independence Day, together with the usual summer dullness, has intensified, if any thing, the prevailing inactivity of all markets.

Copper buying is reported as being fair by some and absent by others, with prices easier.

Buying of tin is moderate and spasmodic with prices steady.

The lead market is quiet and easier.

There is a little more activity in the zinc market at lower prices.

Antimony has again declined.

IRON AND STEEL

Reports have persisted that announcements of fresh reductions in steel prices would be made on July 1 by the Steel Corporation, but there are no indications of such a formal step, says 'The Iron Age'. Actual market developments further confirm what was in evidence last week that both the Steel Corporation and leading independent makers are meeting competition as it appears. This process is causing a gradual settling of prices.

The most encouraging indications are the activity of the administration at Washington in hastening the payment of the Government's debts to the railroads; the prospect that railroad bonds will be accepted by the Government on its counter-claims; and the placing of a fair amount of steel for the repair of cars, with the prospect that considerably more will follow shortly.

The scale of mill operations is little changed, being from 15 to 25% for a number of independent companies and about 30% for the Steel Corporation. There is agreement in the expression coming from several steel-making centres that the falling away in demand is entirely without parallel and that the extent of unemployment is greater than leaders in the trade had believed possible.

The iron and steel duties in the new tariff bill are a surprise to the trade in their close approach to the then fully protective schedules of the Payne-Aldrich Act of 1909.

COPPER

Opinions of the market vary, some sellers reporting a fair business each day for both foreign and domestic account and others asserting that there is practically no demand. Those sellers who refuse to quote less than 13 to 13.25c. for early or July delivery are the most pessimistic, while those who are willing to meet the market reasonably are more optimistic and are selling copper almost daily. For instance one seller sold recently about 100,000 lb. on one day and 150,000 lb. on another with quotations reported on 400,000 to 500,000 lb. on another day which were reasonably sure to result in sales. In such circumstances sellers have done a fair business about equally divided between foreign and domestic buyers and they predict that for June their sales will amount to a fair total, though not as large as in May. While sales of small lots of electrolytic copper have been made as low as 12.50c., New York, the great bulk of the July metal has gone at 12.87½c., delivered, or about 12.62½c., New York, which we quote as the market, these being the prevailing prices for present day business. Lake copper is largely nominal at about the same levels as the electrolytic market, or 12.87½c., delivered.

TIN

Prices of spot Straits tin have been steady to firm all the week, remaining close to 29c., New York, which was the quotation yesterday. On most days the market has been quiet and inactive, excepting one day the middle of last week

when sales, estimated to total from 300 to 500 tons, were made. These were largely purchases by dealers with some consumers sharing interest. Aside from this one day, the market has been almost stagnant. London prices have also been steady with quotations yesterday at £166 10s. for spot standard, at £169 for future standard, and at £167 10s. for spot Straits, all about £2 per ton above the prices a week ago. Arrivals thus far this month have been 1540 tons with 2000 tons reported afloat.

LEAD

The market is generally quiet and devoid of much interest. The only feature has been the reduction late last Wednesday by the leading interest of its price from \$4.50c. to 4.40c., both New York and St. Louis. In the outside market prices have been lower with sales made down to 4.25 to 4.30c., New York, during the last few days of last week, but there was not a broad market. Yesterday the market was fairly stable at 4.40c., New York, or 4.15c., St. Louis, with some sellers quoting the latter base at 4.25c. Statistically this market is the soundest of all.

ZINC

A little more interest is reported but it is small. The market has been stagnant so long that even a flutter of buying is almost sensational. However, some producers at least are more willing to meet the market, due perhaps to low ore-prices and a probable readjustment in labor. During the week values have declined quite sharply so that prime Western is quoted and has sold at 4.25c., St. Louis, or 4.75c., New York, for wholesale lots for early delivery. The market is not active but is showing a little more life than in many weeks and the bottom is believed to have been about reached. Importations have been very heavy in recent months, due to the desire probably to forestall any increase in duty. These stocks have, therefore, depressed the market all this time.

ANTIMONY

Prices are lower with wholesale lots for early or July delivery quoted at 4.87½c., New York, duty paid, with jobbing lots from ½ to ¼c. higher.

ALUMINUM

There has been no change in the reported quotations of the leading interest of 28c. f.o.b. plant, for wholesale lots of virgin metal for early delivery. For foreign metal of the same grade prices vary according to the seller and the source of the metal, or from 22 to 23.50c., New York.

ORES

Tungsten: The market continues exceedingly quiet with quotations largely nominal and unchanged from those prevailing a week ago. This is also true of ferro-tungsten.

Molybdenum: No interest in the market is reported with quotations nominally unchanged at 50c. per pound of MoS₂ in regular concentrate.

Manganese: There is absolutely no demand. While the quotation is 22.50c. per unit, seaboard, for high-grade foreign ore, it could be possible without doubt to shade this on a firm offer.

Manganese-Iron Alloys: The markets for both ferro-manganese and spiegeleisen continues featureless and inactive. A carload lot of spiegeleisen is reported to have been sold. The quotation for the 20% grade is \$30, furnace, as a minimum. On an inquiry for 100 net tons of ferro-manganese for the Government, bids made public reveal prices down to an equivalent of \$72.80, delivered, for the British alloy, equivalent to about \$70, seaboard. This compares with \$75 recently asked. Domestic alloy is still quoted at \$80, delivered, but could be bought at less.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

FRACTIONAL-SIZE AUTOMATIC COUPLERS FOR MINE AND INDUSTRIAL CARS

The design of fractional-size automatic couplers manufactured by the American Steel Foundries of Chicago are identical with those of the full-size standard railway couplers manufactured by this company.

All of the operating features of the full-size couplers are incorporated in these smaller ones, so that they may be operated entirely by means of an operating lever at the side

a coupling; there are no loose links or pins to be lost or misplaced.

The material used in the small couplers is the same as used in the standard couplers, and consists of high-grade open-hearth cast-steel for the coupler body and all other parts that are not dropped forgings.

Fractional-size couplers are made in two designs: the Simplex and the Alliance. The former is the same design as the well-known standard Simplex coupler, of which there are over a million and a half in use. They are noted for their strength, simplicity, and positive coupling action.

The half-size Simplex coupler is furnished in the top-operating type only and is adapted for use on narrow-gauge cars up to 10-tons capacity, such as mine-cars, tunnel-cars, dump-cars, etc. Both lock and lifter are dropped-forged. The standard design weighs 47 pounds.

The three-quarter size Simplex coupler is furnished in the top-, side-, and radially-operated designs, the latter two being recommended where there is danger of the uncoupling rigging being bent from projecting loads. These couplers are suitable for use on narrow-gauge cars of from 10 to 20 tons capacity or on standard-gauge cars such as open-hearth charging-box cars, dump-cars, etc., where it is not desired to use full-size couplers. Standard couplers weigh 124 pounds.

The Alliance coupler represents the latest development in couplers, embodying all of the improvements which have been found desirable to meet the present-day demand of traffic. These improvements are just as valuable in the fractional-size as in the full-size coupling. They consist mainly of interlocking lugs, or pin protectors on the hub or knuckle, and pulling lugs on the tail of the knuckle which interlock with corresponding lugs in the head of the bar. Both of these features add greatly to the strength of the coupler, and by relieving the pivot-pin of the greater part of all strains, prevent wear and consequent loosening, thus greatly increasing the service life of the coupler.

The Alliance half-size coupler is made in top-, bottom-, and side-operating design suitable for narrow-gauge cars of 12-tons capacity, such as mine-cars, tunnel-cars, dump-cars, etc. The weight of the standard design is 57 lb. This is about 20% heavier than the Simplex half-size, but the increase in strength over the Simplex is about 80%.

The three-quarter size Alliance coupler is furnished in top-, bottom-, side-, and radial-operating designs, and is suitable for application to narrow-gauge cars of from 12 to 25 tons capacity, such as mine-cars, dump-cars, etc., where it is not desired to couple with the standard full-size coupler. The weight of the standard design is 145 pounds.

In addition to the standard styles of shanks, all of these couplers can be furnished with any design of shank desired to meet any special requirements. Some of the special applications are couplers to fit in the link-slot on cars formerly equipped with link and pin; round-shank couplers for use on mine-cars, to allow one car to be turned over completely and dumped while remaining coupled in train; and numerous designs of long-shank, off-set shank, and pivoted heads, for electric, steam, and gasoline locomotives.

Fractional-size bottom-operating Alliance coupler

Fractional-size side-operating Simplex coupler

of the car, doing away with the necessity for the operator going between the cars to make or break a coupling. It is this safety feature and the great saving in operating time which has made the automatic coupler such a success on the railroads of the United States.

The operating features of the American Steel Foundries fractional-size couplers consist of a positive arrangement to throw the knuckle open preparatory to coupling; automatic locking of the knuckle when cars are moved together; an anti-creep device on the lock to prevent its creeping up and permitting accidental unlocking; and a lock-set whereby the lock when raised rests in a position above the knuckle-tail to permit knuckle opening freely when uncoupling. This feature does away with the inconvenience and dangerous practice of a man running beside the car and holding up the locking-pin until the cars have parted in making a running-shift. It is also a great convenience when making a cut in a standing train to be able to set the lock and then give the signal from any point at a distance from where the cut is to be made. The automatic coupler is always ready to make

Where it is desired to handle cars such as charging-box cars with a locomotive that also handles standard cars, the fractional-size coupler is placed beneath a standard coupler.

DRILL-STEEL FROM HOLLOW INGOTS

*Hollow drill-steel is made by various methods: (1) The drilled billet with a sand-filled core, the general method used in this country. (2) The drilled, pierced, or the drilled and pierced billet, not sand-filled, is rolled down over a projecting ball much the same as in ordinary pipe manufacture. System (2) is employed largely in Sweden. In Sheffield, England, the general scheme is sand-filling. Swedish hollow drill-steel is particularly good and has a world-wide reputation for excellency. It does not follow, however, that steels made by other methods are not efficient, because they are.

The method employed by the Ludlum Steel Co. in the manufacture of hollow drill-steel is to insert a high-grade low-carbon mild-steel tube, suitably cleaned by sand-blast, into an ingot mold and cast the hot metal around the tube. We fill up the tube with some air-excluding material so as to prevent oxidation and scaling of the inside of the tube, generally using a high-grade sand for this purpose. The ingots are then rolled in the usual way down to the finished bar. The bars are cut to required length and the sand extracted by a special method, which is very speedy and extremely effective.

The tube method of making hollow ingots for the manufacture of hollow drill-steel is a decided departure from the old methods, and the logic of it seems to show that the resultant hollow drill-steel should be superior to that made by the older method. Tests made by the Ludlum Steel Co. to date show that such is the case; whether or not our premises are accurate, we believe that hollow drill-steel made this way will withstand alternating stresses better than anything that has yet been produced of similar analysis. The reasons why we believe the tube method of hollow drill-steel manufacture is superior to the older methods are:

1. Greater freedom from external and internal straining.
2. Because of the inherent small crystal size.
3. Absence of harmful segregations resulting in weakness of the wall of the hole.
4. Less liability for the steel to crack in the inside of the hole during forging or hardening.
5. Toughening effect, arising from the mild-steel wall of the hole, limiting the intense hardening on quenching.

ALLIS-CHALMERS ENGINE-TYPE ALTERNATORS

With the rapidly increasing use of gas- and oil-engines, particularly for units of larger size, and with the continued demand for electric generators driven by reciprocating steam-engines, the 'Engine-Type Alternator' finds many applications in modern central stations, municipal plants, and industrial establishments. This type of generator, used with any of these prime-movers, provides a compact generating unit, which on account of its convenient arrangement, requires a minimum of attention.

Allis-Chalmers alternators are of the revolving-field type, as this construction has proved superior to all others in both mechanical features and electrical performance. The armature-coils are stationary, and hence are not subject to mechanical vibrations or centrifugal force. They can, therefore, be readily insulated for high voltage and, as modern machines are frequently wound for high pressure, anything that contributes to perfect insulation is an important advantage. Moreover, with the stationary armature construction the collector-rings are not subjected to high pressure.

The revolving field is excited by current supplied at low pressure so that the collector-rings are easily insulated and involve no undesirable features. Following the usual practice for engine-type generators, Allis-Chalmers alternators of this type are arranged so that the revolving field or rotor is mounted directly on the engine-shaft. These generators, designated as Type "A1", are therefore regularly furnished without base or bearings, the engine-bearings being used to carry the rotor as well as engine fly-wheel, while the stator is mounted either on the engine bed-plate or directly on the foundations.

Allis-Chalmers engine-type alternators are regularly listed in all sizes up to 1875 kva. for several types of prime-movers, and for the usual requirements of engine-speeds. Machines of larger size or for special requirements can be furnished to meet particular service conditions.

COMMERCIAL PARAGRAPHS

The Dayton-Dowd Co., of Quincy, Illinois, has opened a new district-office, for the sale of pumping machinery, in the Pioneer building, St. Paul, in charge of the George M. Kenyon Co., a firm of engineers of long standing in St. Paul.

The Pawling & Harnischfeger Co., of Milwaukee, has issued Bulletin 6-X, describing the P & H excavator-crane No. 206. The crane moves anywhere on its 'corduroys' designed to give traction on any service, and operates economically by gasoline power. Easily interchanged buckets and devices fit it for a variety of uses. Equipped with a crane-hook, it can be used for handling machinery, laying pipe, and similar work; a lifting-magnet may be attached if desired. With a clam-shell bucket the machine can be used to handle ore, stone, sand, coal, and similar material. An orange-peel bucket serves for dredging and a shovel-attachment can be conveniently utilized for any work where a revolving shovel is required.

In order to handle more satisfactorily its growing de-tinning business in the West, the Metal & Thermit Corporation has constructed and will shortly place in operation in South San Francisco a large new plant for the production of de-tinned billets, in addition to the de-tinning plants already operated by this company for several years at Chrome, New Jersey, and East Chicago. The new South San Francisco plant has been equipped with a large welding-shop containing excellent equipment and facilities for undertaking repairing by the Thermit process. With this new equipment at its disposal the company is exceptionally well prepared to render prompt and efficient service to its Western customers. The new plant will be in charge of Em. Kardos. The cost of the plant is estimated in the neighborhood of \$800,000. The former offices of the company, situated at 329-333 Folsom St., San Francisco, have been moved to the new plant.

The Link-Belt Co. has acquired all of the capital stock of the H. W. Caldwell & Son Co., and Frank C. Caldwell has been elected a director of the Link-Belt Co. Two experienced and successful companies in the conveyor-machinery world have thus joined forces, with the result that the Link-Belt Co. has added two new lines, 'Helicoid' conveyors and power-transmission machinery, to its line of manufactures. While the H. W. Caldwell plant will continue to operate under separate corporate existence and under its present name, the joint facilities of the two companies, and the broader avenues of distribution of the Link-Belt Co. ought to prove of distinct advantage to the customers of both. There will be no modification of the policies of the Caldwell plant, no impairment of its service to its customers, no change in the diversity or character of its product. The plant-management will remain substantially the same, and the new owners, like the old, will proceed on the theory that the goodwill of its customers is the company's best asset.

*Abstract of a paper by P. A. E. Armstrong at February 1921 meeting of the A. I. M. & M. E.

T. A. RICKARD, . . . Editor

FLOTATION of a mixed copper ore at Mount Lyell, in Tasmania, is described by Mr. L. V. Waterhouse in a detailed article appearing in this issue. Several interesting devices will be noted. It is curious that eucalyptus oil is still being used, in admixture with coal-tar. At one time the kind of oil used in a flotation mill varied with the geography; thus pine-oil in the United States, eucalyptus oil in Australia, and camphor oil in Korea.

DIVIDENDS to be paid to stockholders of some of the gold-mining companies of the Witwatersrand indicate a healthy return on the basis of the original investment. On June 30, the New Modderfontein Gold Mining Company set aside, for early payment, an amount equivalent to 42% of its original share-value; the Modderfontein B. Gold Mines company, 40%; the Rand Mines company, 35%; the City Deep company, 20%; and the Crown Mines company, 10%. Unfortunately the public purchased most of these stocks at a big premium, but the returns indicate a handsome profit on the real investment by the original shareholders, if they still retain their stock.

PROSPECTS of a resumption of mining in Siberia seem to be brighter by reason of the negotiations in London between the representative of the Soviet government, the British Board of Trade, and the officials of the Russo-Asiatic Consolidated Company. This company has mines and smelters in the Altai district and on the Irtysh river. It is an English company, but it has employed, and is still employing, several well-known American mining engineers, notably Mr. J. Power Hutchins. The Board of Trade has signified its approval of the agreement whereby the Soviet Government returns the Russo-Asiatic concessions to that company and permits a resumption of work. It is stated, in the 'Financial Times' of London, that the company, a large affair, capitalized at £12,000,000, has an organization and equipment that will enable it "very soon to produce supplies of gold, copper, lead, zinc, etc., all so much needed by Russia". It is conceded that the company shall have "the right to allocate a substantial proportion of its profits for the payment of an adequate dividend to shareholders, that a further proportion shall be laid aside as reserves for future requirements, and that only on the surplus shall the Soviet Government levy tax-

tion, say, to the extent of a quarter". Of course, adjectives like 'adequate' and 'substantial' leave scope for interpretation, but the agreement is an interesting example of a compromise between the forces of sentimental anarchy and those of industrial capitalism. The Soviet Government, moreover, we are informed, "is prepared to lend all assistance possible to the concessionaires in the way of facilitating the supply of labor and transport". This sounds delightful, but, as we are nearer to Missouri than our friends in London, we have our doubts and even our suspicions regarding both the ability and good faith of Messrs. Lenin, Trotzky, *et al.*

IN this issue we publish an article that discusses the principal factors bearing upon the establishment of an iron and steel industry on this Coast. We heard the article delivered as an address by the author, Mr. Clyde E. Williams, on the occasion of the last meeting of the International Mining Convention at Portland. It seemed to us to contain much useful and interesting information and we hope that it may elicit further discussion from those who have investigated the subject. Obviously, the Pacific Coast will not achieve industrial independence until it produces its own iron and steel. We feel certain that it will; the question is, when? We hope that Mr. Nicol Thompson, of Vancouver, Mr. B. L. Thane, of San Francisco, and others will state their views for publication in our pages. We take the opportunity of adding that the work done by Mr. Williams marks the useful co-operation of the College of Mines, in Washington University, at Seattle, with the Northwest Experiment Station of the U. S. Bureau of Mines.

FROM the Kansas State Agricultural College comes a true word. Mr. H. W. Davis, the director of that useful institution, asserts that "newspapers and magazines control the language in this country". He told the National Education Association, in convention assembled, that a newspaper 'story' that carries its message 'across' has done its duty; in short, that good English is effective English. We agree that the development of our language is largely in the hands of those who use it most—the newspapers and periodical press; and that is why we deplore the fact that they indulge in so much sloppy writing, because they are undoing the work of the schools and universities, where our youth of both sexes is taught,

among other things, how to use the language correctly. Where we disagree with Mr. Davis is in his supposition that the English of the newspaper story is usually effective; it seems to us, from daily experience, that much of the reportorial work is ineffective because it is written carelessly and ignorantly, by those who prefer the language of the gutter to that of the library.

DISCUSSION this week is again enriched by several notable contributions. The first is from Mr. E. M. Hamilton, who writes on a subject in which he has won recognized place as a specialist, apart from the fact that he ranks among the most scholarly and conscientious of our technical writers. A soldier, Mr. Waldo Lee Clark, asks that special consideration be shown, in the matter of assessment work, to those who were disabled in the War; and his plea will meet with sympathy. A prospector, Mr. A. G. Dingle, complains that he cannot get anybody to inspect his mineral discovery, but we feel certain that he could get friendly treatment in the matter of an ore-test, if he made the acquaintance of those at the School of Mines of his own State. Mr. L. C. Denny recognizes the honest intellectual effort that has been made to improve the mining law, but, like others, he demurs to the requirement that the claim-lines must be run so as to conform with the existing subdivisions of the General Land Survey. This protest is seconded by Mr. Frank P. Davis, who likewise anticipates that the rigid enforcement of such a regulation will prove a hardship to many prospectors and be impracticable without a systematic survey in localities where the Land Survey is incomplete. He is unfair, we think, to the mining engineer, in supposing that the members of our profession mean to euhre the genuine prospector; the regulations, of course, are meant to simplify and to assist the location of mining claims in the interest of the legitimate prospector; they should be discussed from that point of view, and corrected if they do not further their implicit purpose. The last contribution to 'Discussion' is a long, and interesting, one, from our correspondent in Mexico, Mr. Robert B. Brinsmade.

TROUBLE has arisen at Hornsilver, 28 miles south of Tonopah, in Nevada, over the interpretation of the Statute regarding the performance of assessment work on unpatented mining claims. The issue raised is this: must the prescribed amount of work be completed on the last day specified, or may the work continue until completed, providing a start was made before the expiration of the period provided by law. The particular claims involved comprise the property of the Southwestern Mines Company, for which Mr. S. H. Brady is receiver. Two of the 11 claims are of particular value because they adjoin, on the strike of the vein, the Orleans claims from which Mr. J. W. Dunfee is mining rich ore. A small mill is situated on the property. It seems that Mr. Brady arranged a lease with Mr. Tim Connolly, with the expectation that his labor would satisfy the requirement of the law as to assessment work. The lessee, however, de-

serted the claim, presumably without at once notifying Mr. Brady; when he finally learned of Mr. Connolly's departure, the receiver sent to the property a party of miners who started work at 8 p.m. on the night of June 30. On the morning of July 1, twelve men, one of whom was Mr. William Cavanaugh, the original locator of some of the claims, posted new notices of location for each of the 11 claims. They are said to be ready to go to court to obtain title to the property. However, we venture to predict that further legal advice will dissuade them from starting any litigation. The courts have repeatedly held that if a man start work prior to the expiration of the year, and continue it with reasonable diligence and without interruption until the prescribed amount has been performed, any adverse claimant is in the position of a trespasser. The Act of Congress approved by the President on December 21, 1920, whereby the final date for the work of 1920 was deferred until June 30, 1921, obviously is special legislation, but it seems improbable that any court would deviate from the established precedent on that account.

SUCCESSFUL industrial operations abroad depend, in no small measure, on confidence in the stability of the government in power; without this confidence, capital looks elsewhere for investment opportunities. An autocratic and erratic president may plunge a country into chaos; a weak monarch can do no more. Conditions in Peru are being watched with some concern, although the national game of politics has been played so uninterruptedly of late years that the Peruvians themselves, as well as their neighbors, are past being surprised at what does or may occur. Mr. A. B. Leguia, the President, assumed office under circumstances that are reminiscent of the plots of a Gilbert & Sullivan opera. He was a candidate for President, and the elections were to be held in August 1919. Not willing to rely on the popular choice, he drove to the presidential palace in the early hours of July 4—choosing the date so that the sound of any promiscuous shooting would be attributed to the exuberance of the Americans resident in Lima—and seized the reins of Government, apparently without opposition. The military were annoyed at being disturbed at such an hour, but otherwise the revolution passed off in a manner typically Peruvian. Mr. Leguia assumed office without national protest. His friends were jubilant, for the majority of them trusted their favorite, and honestly thought that the revolution would be for the ultimate good of Peru. But they were soon disillusioned as to Mr. Leguia's intentions, as well as with regard to his fitness for the high office of Chief Executive. Many of them saw the handwriting on the wall, and beat a hasty retreat to Paris or to London. Recently the President has become arrogant. Needing money for the centennial celebrations that are to be held to commemorate the anniversary of the independence of the country, on July 28, he applied to the banks for a loan; but the financiers of Lima were not impressed, and they refused to lend. The President then retaliated by prohibiting them from en-

gaging in foreign business; and the money he needed was raised through the aid of British oil-operators in Peru. Three newspapers have been suppressed recently on account of their outspoken criticism of the President's autocratic actions; the university of San Marcos has been closed; and reports indicate that Mr. Leguia is succeeding in killing all opposition to himself and his tactics by banishing some of his political opponents to Australia, and by imprisoning the remainder on an island quarantine station near Callao. The administration has been regarded as a joke for many years, and this is one of the reasons why the country is rightly classed among the unprogressive States of South America. The people appear to take the antics of their political mountebanks as a matter of course; they are too tired to argue about, or to protest against, the conditions that seriously impede the development of Peru.

THAT the use of good English is a specialized study in university training, rather than an essential in every phase of the curriculum, is an objection that is voiced by an anonymous member of a faculty club, whose opinions appear in a recent issue of the 'Christian Science Monitor'. The standard of undergraduate English is on the decline. The poor composition of college men has been attributed to the newspapers; an educational diet that ignores Greek and Latin is said by others to be responsible; but it is clear that neither of these, in itself, can be the cause. The trouble, in the opinion of a professor of English, is because the entire question of verbal expression of thought is a matter that is confined to the English department of the university, which, it is clear, should not be obliged to shoulder the whole responsibility for instruction in written and oral expression of specialized branches of learning. The student, for instance, does not bring his biology into the classroom for inspection; but he does take his English, or a substitute for it, into the biological laboratory; the professor of biology incurs a responsibility in this connection; and if he realizes that knowledge and adequate expression cannot be divorced, he will not throw the entire responsibility upon the department of English. He will see that every man in the faculty must be, from time to time, a teacher of expression. At present it is natural for the freshman, when he leaves the English classroom, to cast aside all concern about commas or dangling participles; they are mere English, in his opinion, for which he hopes to get separate credit. In the history class he is concerned with facts; and so he writes and speaks as he pleases. It is this separation of expression from thought and knowledge that defeats all efforts to improve undergraduate English. The remedy, according to the professor, is co-operation; failure will result if all is left to the department of English; it is folly, he says, to expect that one course in the freshman year will uproot all the weeds of faulty speech, and will sow the seeds of excellent expression that will continue to blossom throughout the student's later life. Only steady and concerted effort on the part of the entire

faculty can achieve such a result; students must be taught that true knowledge and clear expression are one and inseparable. Satisfactory speech and writing will result only when in every class-room—and whatever the subject being taught—accuracy, correctness, and even grace of expression are demanded of all students at all times in their written and in their oral work. We consider that there is much that is logical in this viewpoint. In too many cases the acquisition of an easy and correct style in the presentation of technical facts comes, if it comes at all, long after college days have passed.

Oil and Friction

Vehement denial, says a press dispatch, was made recently by Viscount Curzon that Great Britain seeks to control the world's undeveloped oilfields. This is one of the questions that are supposed to 'strain' friendly relations between the two English-speaking countries, and it is well to refer to it if by doing so that strain can be lessened or removed. Lord Curzon denied that the British government is "co-operating with British interests to secure an oil monopoly"; he said that such an idea was "entirely without foundation". We accept his statement, of course, because a man of his character and position does not say what is untrue. He acknowledged that "there were some restrictions" on exploitation for oil in British territory, but that was "during the War", and the restrictions "have now been removed". Lord Curzon stated that whereas Great Britain imported 3,368,600 tons of oil in 1920, her domestic production was only 166,000 tons. Of the oil imported, 61% came from America, 37% from other countries, and only 2% from the British possessions. Yet 90% of the British navy is now oil-fired, and the use of oil is increasing in the mercantile marine; so that the urgency of a supply of oil is manifest. Canada's oil exploitation is confined to companies of British register, but the chief of these is the Imperial Oil Company, a subsidiary of the Standard Oil Company. Various charges and counter-charges have been made in consequence of the rivalry in oil exploitation, of the British in Persia and Mesopotamia, and of Americans in Colombia and Mexico. Much of the newspaper talk is misinformed, if not malicious. For instance, the shipment of oil from Wyoming to a Canadian refinery owned by the Imperial company is instanced as a British depredation, whereas the Imperial company is controlled in the United States. Not long ago the same authority, Lord Curzon, who, we believe, is Secretary for the Colonies, denied the rumor that his Government was interested directly or indirectly in the Royal Dutch combine, although our Secretary of State, Mr. Hughes, thought it necessary to send a note to Holland demanding participation in the Djambi oilfield, which is owned exclusively by the Dutch. We believe in protecting our nationals in their mining enterprise abroad, whether in Mexico or in Persia, but, as the 'New York Journal of Commerce' said wisely not long ago, "We cannot be international where American foreign

trade is concerned and national where the foreign trade of other countries is at stake".

American enterprise is that of individuals and syndicates, it is in no way backed by our Government, whereas the British government during the War did take active steps to stimulate the production of oil within its own or protected territories, and that is why objection has been raised by some of our oil-operators, who demand a free field for their competition. The world needs the initiative of the Dohenys and Bedfords, just as it needs that of the Cowdrays and Deterdings. Our people control 80% of the oil production of the world, and we ought to be able to meet others in competition without getting hot about it. There is need for the enterprise of all in finding and producing the ever-increasing quantity of oil demanded by modern industry. Surely it makes no difference whether an American exploits oil in Burma or an Englishman in Wyoming, provided the oil in the one case goes to the English market and in the other to the American market, as assuredly it would in either case. The English-speaking peoples cannot afford to quarrel over such matters, when issues so much bigger are at stake. We have been comrades in arms recently in defence of our civilization; we have a common purpose in striving for world peace; our peoples desire intensely that general disarmament may be brought about by conference between our leaders and those of other nations; most of us are sick of the petty jealousies and mean recriminations that have followed the successful conclusion of our war with Germany and her dupes; is all the fine emotion to be lost in petty spites and commercial rivalries? Can we not recapture the vision of the heroic years but lately past, and once more rise above all meaner things to a plane of manly goodwill and friendly competition?

Evasion of Licensing

The problem of the licensing of engineers is beset with difficulties, because the passage of legislation may result in evasion, on the one hand, or it may inflict hardship, on the other. In the State of New York there is a law to provide for the licensing of professional engineers, but unfortunately it permits corporations and unrestricted partnerships to practise, irrespective of the conditions of this law. They are exempt. This particular State legislation was enacted in the face of strong opposition from the American Society of Civil Engineers, among others. The American Association of Engineers, founded to promote the economic and social welfare of the members of the profession, at its recent convention in Buffalo, adopted a resolution that indicates opposition to the enactment of laws for the licensing of engineers, which, at the same time, permit corporations, unrestricted partnerships, or joint-stock companies to practise in a similar capacity and without legal restraint. Such a law is discriminating; its enforcement nullifies the purpose of licensing by permitting groups of men who are not engineers, to do, indirectly it may be, those things that the

individual who is not an engineer is prohibited from doing; it allows them to act in a professional capacity in the same manner as one whose technical training and moral qualifications have been subjected to a searching examination, and who is permitted to practise only after he has paid the prescribed fee. Such legislation sanctions a procedure that may become immoral, in permitting an aggregate of individuals, in whole or in part composed of men who are not engineers, to serve in the dual capacity of supposedly disinterested advisers to a client, and at the same time as self-interested financiers, sellers, or contractors in the execution and supervision of work in connection with which such advice is given. Such sanction is opposed to the sentiment that an engineer shall not be personally interested, directly or indirectly, in a company with which he has relations in behalf of his employee or client; it sanctions a condition under which an engineering corporation may have bankers, manufacturers, and contractors on its board, who may so dominate the policy as to influence the management, including its engineering employees, in the preparation of reports, plans, contracts, and specifications, and in the supervision of work, in such a manner as to favor the outside interests of such directors and to the injury of the public. Thus the professional engineer in the employ of an engineering corporation or unrestricted partnership, which is made up in whole or in part of persons who are not engineers, is relegated to a position of anonymity, and is relieved of all professional responsibility to the client; he is placed under the direction of those whose primary interests in the work may be in the making of a contractor's profit. Conditions are permitted under which a group, constituted in whole or in part of men who are not engineers, may violate, with impunity, the codes of ethics that have been adopted by various professional societies for the guidance of their members and for the protection of the public. Corporations are free to advertise in a blatant manner and to solicit patronage; professional engineers are restrained from so doing either by good taste or from a sense of professional etiquette. There have been instances in which engineering corporations have adopted methods that are in direct violation of the codes of professional ethics to which some of their officers or members in their individual capacities have subscribed. This, it is maintained, is unfair to the independent engineer, and is destructive of that respect for the profession which should be of public concern. The result is that engineers are forced to give up independent practice and are obliged to abandon purely professional work in order to affiliate themselves with contracting organizations, thus denying the public the disinterested and effective service of the men who, hitherto, have been chiefly responsible for progress in the art of engineering. We have given the Association's argument in full detail; the subject warrants this action. We suggest that the Mining & Metallurgical Society of America, which is now considering the question of licensing in all its aspects, should include in its researches a study of this phase of professional work.

DISCUSSION

Cyanide Regeneration During Precipitation

The Editor:

Sir—Regarding the question of cyanide regeneration during zinc precipitation raised by Mr. Del Mar, in your issue of June 11, I think that both in his article and in other writings on the same subject the point at issue is obscured by a failure to distinguish between free and total cyanide. The author of the article does not apparently recognize such a distinction, and yet it is an important one. By "free cyanide" is meant, of course, the simple uncombined cyanide salt in solution. The term "total cyanide" is more conventional, since such compounds as ferrocyanides and sulphocyanates are excluded; indeed as ordinarily used it does not even cover the gold, silver, and copper double cyanides, since the first two are not titrated in terms of cyanide by the ordinary silver nitrate method, and the copper only in part or not at all; so that for practical purposes the term "total cyanide" may be taken to mean the free or uncombined alkaline cyanide plus the double zinc cyanide, Na_2ZnCy_4 . Now there is a distinction to be observed between these two compounds both (1) as to their determination in the solution and (2) as to their relative functions in the dissolving of the precious metals.

(1) The nearest approach to a correct determination of free cyanide by the silver-nitrate method is made by titrating to the first faint bluish-white cloudiness produced in an originally brilliantly clear solution, and needs to be observed carefully with the right incidence of light and against a dark background. The determination for total cyanide (understood as already explained) is made by adding potassium iodide indicator and titrating to the yellow opalescence characteristic of silver iodide. For the accurate determination of this compound it is usual to add caustic soda as well as KI to the solution to be tested, but if the free alkalinity (whether it be the result of lime or caustic soda) already present in the solution amounts to about 0.1% in terms of NaOH, the reading obtained will be the same as if caustic soda be added; so that the common practice of adding KI indicator and titrating to the yellow end-point will give a reading that often represents the "total" cyanide or the free plus all the double zinc cyanide, and will nearly always give a reading in excess of that demanded by the free cyanide alone. The above distinction in titrating methods has to be modified somewhat in cases where a considerable amount of copper is present in the solutions, but for the purpose of the present discussion it may be allowed to stand.

(2) It may be asked, "Why trouble about any distinction in the titrations when the double zinc cyanide is as effective a dissolving agent as the single alkali-metal cyanide?" But is it? I maintain it is not. In the case of silver I made a long series of experiments some years ago on precipitated silver sulphide dried and pulverized, and found that a solution of Na_2ZnCy_4 had almost no dissolving action on it, such small action as there was being accounted for by the slight degree of dissociation of the double salt in solution, since a free cyanide titration made as already described indicated the presence of a small quantity of uncombined cyanide.

On gold, the action of the double zinc cyanide may be considered open to question. Julian and Smart state that their experiments showed that gold was soluble in K_2ZnCy_4 , the ratio of efficiency being 96 as against 109 for simple KCy solution. This observation, however, is somewhat marred by the admission that the zinc solution was "probably" saturated with zinc, implying that the actual constitution of the solution was not determined. The same authors quote W. R. Feldtmann in support of the solvent action of the double zinc compound, but the quotation deals only with the effect on its dissolving power produced by addition of alkali, which is not the point at present under discussion and belongs to an entirely different category, since we are now dealing with the actual dissolving power of the double salt in its combined state and not with its potential dissolving power after having been partly or completely dissociated by addition of alkali or by other expedients. J. A. Sharwood (American Chemical Society, Vol. 25, p. 580) states that the solvent action on gold of solutions of potassium zinc cyanide is less than that of a solution of simple potassium cyanide containing the same amount, or one-half the amount, of cyanogen in equal volumes, and that it is increased by addition of caustic alkali. Gerard W. Williams (Journal Chem., Met. & Min. Soc. of S. A., Feb. 1904, p. 298) in summarizing the results of a long and careful investigation into the subject says that "although the 'free' cyanide increases proportionately with the alkali present, it is not practical to have all the cyanide in the double zinc cyanide in the 'free' state, owing to the secondary effects of an excess of alkali on the solutions. Hence the bulk of the K_2ZnCy_4 present is inert and useless for the purpose of solution of gold".

To return now to the article of Mr. Del Mar, it is easy in the light of what I have already said to conjecture what has given rise to the observation of an apparent

regeneration of cyanide during the act of zinc precipitation.

1. He states that KI indicator was used in the titration, and it may be assumed, therefore, that addition of silver nitrate was carried to the usual yellow opalescence. Under these conditions the reading obtained would indicate both the true free cyanide and a part or all of the double zinc cyanide also.

2. The ore dealt with was chiefly a silver ore and therefore the press-head solution would contain some double silver cyanide, which would not be recorded as cyanide in the titration.

3. In the press-tail solution the silver has been replaced by zinc and its associated cyanide is now recorded as such when titrated with KI indicator to the yellow end-point. Hence the reading obtained on the press tail is higher than that on the press head.

Had the titration in both cases been made to the first faint white cloudiness and not to the yellow iodide opalescence it would have been found that a considerable drop in the free cyanide content of the solution had occurred during its passage through the zinc-precipitation process. This I have found to be invariably the case, and it is quite in accordance with the accepted theories of the reactions that take place during precipitation. That this fall in free cyanide during precipitation does not necessarily imply the loss of the whole of cyanide apparently consumed I have always maintained, since a part of the inert double zinc salt is usually dissociated and rendered available (in other words, regenerated) when the solution comes in contact with fresh lime, as happens when it is pumped back to the mill or to a new charge of ore. Sulphides in the ore may also produce a further regeneration from the combined cyanide by formation of alkaline sulphides which would precipitate some of the combined zinc as sulphide with formation of simple alkaline cyanide.

It is thus evident that while some of the free cyanide consumed in dissolving the silver in an ore may later on be rendered available for further use through the indirect action of zinc precipitation, yet such regeneration does not take place in the act of precipitation but is a secondary result produced in the previously precipitated solution by contact with alkalis or other substances.

Regarding the three propositions that Mr. Del Mar offers for consideration at the end of his article, there is no doubt that the addition of lime (or caustic soda) to a zinc-press tail solution will regenerate free cyanide from the double zinc salt, and the increase may be observed by titrating to the true free cyanide end-point. As to the form assumed by the zinc as a result of the reaction, if the alkali added be caustic soda the zinc would no doubt remain in the solution as sodium zincate. If the alkali be lime there may be a formation of an insoluble zinc compound, either calcium zincate or, as Walter Virgoe supposes (*Journal of Chem., Met. & Min. Soc. of S. A.*, August 1903), in presence of carbonic acid, a double carbonate of zinc and calcium.

The expedient of adding sodium carbonate to the barren zinc solution I have never tried, but its first effect would, of course, be to precipitate the lime as carbonate with formation of caustic soda

The substitution of caustic soda for calcium hydroxide would no doubt prevent any precipitation of zinc, which would then remain in solution as sodium zincate.

San Francisco, June 25.

E. M. HAMILTON.

Assessment Work

The Editor:

Sir—I appreciate the position that you take on the question of assessment exemption. I feel that civilians should not be exempted but soldiers who were disabled in the service of their country and because of their disability should not be penalized by the Government failing to exempt them from assessment duty. The Committee of Mines and Mining, of the U. S. Senate, is considering it most seriously. It seems only fair to our disabled soldiers to exempt them from assessment duty as their condition physically cannot permit them to do their work, and their financial sacrifices during the War were such that they have no surplus now for the work. A paper like yours could help it out.

Tucson, Arizona, June 19.

WALDO LEE CLARK.

[We sympathize with this plea, naturally, and hope that some way may be found of putting it into effect at Washington.—EDITOR.]

Prospecting

The Editor:

Sir—I have been reading your articles on prospecting and your invitation for a discussion on its problems. It is good and timely that this should be done, for in our little city the buying on margin has brought disaster to many an individual; one I know has lost over \$100,000 in the recent drop of standard stocks; others have lost homes, automobiles, and are down and out. They have not a dollar to finance mines at their very door. We have been working on mines for 15 years, two men working steadily the year around, and we cannot find even one who will go out and give them the look-over. What the average prospector needs most is ore-testing facilities, by the State. I wrote to the head of our mining school, and he curtly informed me they could not tell what our ore contained but would look it over if we would send him some of it; our copper ore is complex like the Rossland ore; our gold-iron property needs a mill of some kind to be selected by an engineer. I think the porphyry will show good mill-values in depth. The silver vein is great; we shipped a test lot of ore to the Washoe smelter (now shut-down) last year and they charged \$7.50 for smelting, \$5 for sampling, and this, with the haulage charge, makes it unprofitable at 38 oz. per ton. What the

prospector needs most is some means to get in touch with capital that can help to patent and equip the property with air-drills, etc., as well as a mill to reduce the ore at its source. We bought 50 lb. of 60% 'powder' and it cost \$18.50 at the store in town. The factory is at Ramsey, only eight miles from here. No wonder the Du Ponts can pay 1000% dividends. Big business is strictly against the prospector at every turn; while immense areas lie unprospected that are richer than anything yet developed. You will find a small circular enclosed, for all our treasury stock, 600,000 shares, is unsold and it is impossible to sell any stock in a concern that has the ore. Please excuse this long statement, but it is the story of the modern prospector.

A. G. DINGLE.

Anaconda, Montana, June 14.

[Our correspondent ought to send a sample, not a specimen, of his ore to the Montana School of Mines; we believe that he would obtain the information he appears most to need.—EDITOR.]

Revision of the Mining Law

The Editor:

Sir—A revision of the existing mining law is most vitally needed and the effort now being made seems to have all of the indications of being honestly and painstakingly undertaken, as is so well pointed out in your issue of June 18. Needless to say there has been a deplorable lack of uniformity in the laws of the various States and, even worse, there has been no general code that adequately covers the requirements in any new locality where local conditions compel a variance from the strict following of the statutes.

Alaska is a pitiful example of this. So much of the great wealth of the North was squandered in litigation that found its basis, primarily, in the unsuitability of the laws of the 'States' to the conditions there. In the formation of a new general code it would seem to me that no effort should be spared to provide for the protection of the prospectors and first locators in all new districts—especially districts outside of States already having more or less complete statutes covering their own peculiar problems.

Equally important with the provision for protecting locators and mine operators in new territory, and correlated to it closely, is the matter of laying out claims along lines conforming to subdivisions of the General Land Survey.

While such a law would have the valuable effect of appreciably lessening litigation through the elimination of fractional, blanket, and overlapping locations, it would put upon the prospector and locator an unjust burden in two ways. First, one always wishes to run his claim along the line of strike of the lode or the channel of a stream. It almost invariably happens that the course of a creek is the line which should be followed in making a placer location to permit the miner to realize his richest returns. Second, it is often most difficult to

follow survey lines, and failure to do so under the newly proposed law would often mean loss of valuable ground and sometimes of development work. The outcome might be litigation not unlike what now often results from lack of regular boundary.

It is better to have fractions and over-lappings than for a prospector or operating company to lose the reward of discovery and pioneering of a district!

L. C. DENNY.

Fresno, California, June 28.

The Editor:

Sir—I have just seen the draft of the new revision of the mining law in your issue of June 18. Some parts are all right, but others not so. The conditions with regard to position of end and side lines, the date for the start of the calendar year, and, in cases where it is convenient, the location in legalized sections of the land survey, are all right. But I do make a big protest against rigid enforcement, as it is almost impossible for a prospector to comply unless he has a surveyor, with transit and a couple of rod-men, at his heels most of the time. Much of the public domain has not been surveyed, particularly in the mountains; maybe a line was run 40 years ago, correctly or by guess. I have been running lines for 40 years with a watch, a compass, or a Brunton, and it is difficult to find out where you are. Lots of corners that were put up have been taken away, buried, or destroyed by the big cow-men. The Government knows about it, but does nothing, as someone drawing Government pay is behind them. It is effectual in keeping the little homesteader out, as it would cost him two hundred dollars to find out if the land is owned or not. They also make it difficult for the prospector. A month ago I was prospecting where it would have cost me \$250 to find out what county I was in. I have been where we could not tell which State we were in without incurring big expense.

In a year's time, after the Bill becomes law, we must get our claims surveyed and pay the recording fee; this would not be constitutional. We are satisfied with our present title, without incurring this extra expense. The land survey for claims and the making of a new title for claims, would be cause for much future legislation. This would give the engineers and surveyors permanent jobs, and the lawyers could cut in with their litigation. I am in favor of a law that would benefit them in any way, but not at our expense.

The mining engineer has very nearly killed prospecting since we lost the small promoter; and it looks as if he wanted to ball us up on the mining claims we are now holding. I wrote an article about the revision of the mining law in the 'Press' of June 13, 1914. There was much discussion; but what is the use? Any law that was made to help the prospector or small-mine owner would be jumped upon by the mining engineer. Why doesn't the Committee get a few well-known prospectors to tell them about their part of the game? The fundamental part of mining is the prospector's first location of a mining claim.

When the Utah legislature changed their laws in regard to mining 25 years ago they got two well-known prospectors to explain their views. The ideas were put into effect, and there was no kick from anyone, although the new laws were harder on the prospector than were the former ones.

FRANK P. DAVIS.

Fairview, New Mexico, June 23.

Taxation and the Mineral Industry

The Editor:

Sir—Since the first year of the War, we have had to pay four or five times as much taxation, annually, to the Federation as in former years. Like a new broom, the Republican Congress in session is now engaging in sweeping away the cobwebs of Democratic taxation in favor, perhaps, of a new set of cobwebs of its own. So I beg leave to elucidate a few of the general principles of taxation, disentangled, as far as may be, from the partisan webs that bind most of our periodicals, and many of our professional economists, when discussing this delicate question.

Practically, taxes can be obtained from five sources:

- A. The consumer of merchandise.
- B. The producer of merchandise.
- C. The laborer.
- D. Capital (cash, buildings, machinery, and other labor products).
- E. Legal privileges and monopolies (land values, and patents or copyrights).

As regards their incidence, taxes may be classified as either 'direct' or 'indirect'. The first are levied directly on persons or property, the second on merchandise in transit from the producer to the consumer. To assure a system of taxation which shall be difficult to evade and which cannot be shifted from the first payer to others, in a disguised form, two Golden Rules of Taxation have been enunciated:

I. Tax only objects which cannot be hidden or spirited away.

II. Tax only objects which cannot be reproduced, for only then will the tax rest on the original tax-payer. Every tax on objects capable of being reproduced can be shifted, in the form of higher prices, to the consumer. Moreover, such taxes tend to discourage production.

In the following table I have arranged 15 tax classes with reference to their incidence, origin, and conformity with the Golden Rules:

No.	Name of tax	Incidence	Origins	Rule I	Rule II
I	Export	Indirect	B and A	No	No
II	Import	"	A and B	"	"
III	Merchandise-sales	"	A	"	"
IV	Land sales	"	E	Yes	Yes
V	Real estate taxes	"	E and D	"	"
VI	Profits	Direct	C, D, and E	No	No
VII	License	"	A and B	Yes	"
VIII	Land value	"	E	"	Yes
IX	Unearned increment	"	E	"	"
X	Real estate	"	E and D	"	Partly
XI	Personal property	"	D and E	No	No
XII	General property	"	D and E	Partly	Partly
XIII	Income	"	C, D, and E	No	"
XIV	Excess profit	"	E and C	"	"
XV	Inheritance	"	D and E	Yes	Yes

I. The Export Tax falls on producers, except in the special case where the exporting country sets the price for the commodity in the world market—as in the case of German potash or Mexican henequen—when the tax might be shifted to the consumer. The inhibition against an export tax in our Constitution is a needless handicap for the Government, in its control of exportation; for it leaves no middle ground between free trade and a complete embargo. By an export tax, a government can favor its domestic consumers at the expense of its own producers and to the detriment of the foreign consumer of the commodity. Thus an export tax on pig-copper would favor both our brass founders and consumers, and advantage the former in their competition with foreign founders, while our copper miners paid the piper.

II. The Import Tax has the opposite effect to the Export Tax, because it generally falls on the consumer. Only in an exceptional case (where the domestic market can be fully supplied by our producers at the world price of the commodity) would the foreign producer be obliged to pay the tax before he could enter our markets. These statements seem almost self-evident, and yet there is no economic subject that has been more obfuscated, in an effort to confuse the popular mind, than that of the tariff. Originally devised as a source of revenue at the expense of consumers of foreign merchandise, the Import Tax has had its greatest modern development as a means of 'protecting' domestic producers by raising the price of commodities in the home market.

Free competition, improved transportation, and new inventions tend to lower the cost of living, and are praised as beneficent, but often a tariff, designed for the special object of increasing prices, will be lauded to the skies. The dumping of foreign goods on our shores at trifling prices may seem a calamity for some producer, but I fail to understand why any consumer should object to getting the most for his money. As a temporary premium to aid the establishment of new industries, a protective tariff may be defensible; but even for this purpose it is far costlier than a direct bonus paid to the new producer, in proportion to his output, as was long ago discovered by progressive British colonies such as Canada.

But what of a system of *permanent* protection? At its best, it means the supporting of certain unprofitable industries at the expense of the rest, and is as sound commercially as would be the indefinite continuance of a hopelessly unprofitable mine by a company through subsidies paid from its dividend fund. At its worst, it means the plunder of domestic consumers by means of a monopoly formed by producers, who set their prices at the world price plus the tariff, irrespective of cost of production. This has been done in many instances, and in connection with the sale of borax, aluminum, iron, lead, soda, lime, and cement.¹

III. The Merchandise-Sales Tax, when assessed nationally, must always fall on the consumer and will, therefore, like all indirect taxation, not only increase

¹'Protection and Free Trade', by Henry George, Chap. XI.

prices by the amount of the tax but also by an additional sum to represent the interest and profit on the capital advanced by the merchant to pay the tax. Hailed as a new discovery by our contemporary statesmen, this tax has long been a favorite in Spanish countries. In Mexico it exists as a stamp tax on all sales and at the rate of $\frac{1}{2}\%$. An extreme form of this tax (rate 10%), applied in Holland by the notorious Duke of Alva in the 16th century, was one of the chief causes of the revolt of that plucky little country against Spain.² The United States excise levy on liquor and tobacco is a form of this tax.³

IV. The Land-Sales Tax will fall on the landowner, because land cannot be indefinitely reproduced, like merchandise, and its price is therefore not set by cost of production but represents merely the capitalization of net yield after the essential costs of operation—wages and interest—have been met.³

V. The Real-Estate or Improved-Land Sales Tax comprises two levies, one on land and the other on its improvements. The first does not affect prices, as it falls on the legal privilege of land-owning; but the second falls on the economic capital represented by property such as buildings, and will therefore increase house rents.

VI. The Poll Tax is an annual sum collected from each citizen as such, irrespective of his wealth, and will fall on labor, capital, or land accordingly as the payer gains his income from one or more of these sources. This tax often represents a commutation in money of the medieval duty of every citizen to contribute, annually, one or more days of unpaid labor on the public roads. It tends to increase wages and, consequently, the price of commodities.

VII. The License Tax was the favorite local method of levying on liquor saloons until the inauguration of national prohibition. For a decade it has been used by the Nation in the form of a tax on corporations, assessed according to their capital, for a permit to do business. This tax will always fall on the consumer; except when its payer is exposed to free competition from other districts or countries, where the tax is not levied, in which case it may be found impracticable to shift it from the producer's shoulders.

VIII. The Land-Value Tax is the most direct form of levying on legal monopoly, as the ownership of land is by far the most important form of it. As far as I know, the earnings of patents and copyrights have never been specifically attacked by taxation, though they have undoubtedly been made to contribute through such levies as the Income, the Excess-Profit, and the Inheritance taxes. The Land-Value Tax agrees perfectly with the two Golden Rules and cannot raise the cost of living, because land rent has no effect on the price of commodities. Whether this tax be large or small is a personal matter between the landowner and the government; what the

latter may gain the former will lose, as this tax cannot be shifted elsewhere.⁴

IX. The Unearned-Increment Tax is levied on the increase in selling value of land, computed between two transfers or, in default of such, at stated intervals. It has been adopted widely in Germany and England to absorb for society a portion of the future increase in land values, while leaving to the landowner that land value accumulated in the past which could only be absorbed by the Land-Value Tax itself. It was also used in Kiao-Chau, China, during German rule, as a means of avoiding undervaluation in the assessment of the Land-Value Tax. I consider this tax an awkward device, if used for the purpose of correct valuation, and one tending to complicate a correct settlement, later on, of the land question.

X. The Real-Estate Tax is a combination of the Unearned-Increment Tax with one on buildings and other landed betterments. As the latter levy affects capital, it tends to raise the rate of interest and house rent, and to discourage construction.

XI.—The Personal-Property Tax is designed as a levy on chattels of every kind from stocks and bonds to earrings and pug dogs. As most of these objects have a custom of disappearing, shortly before the visit of the assessors, this tax has never been much of a success as a revenue-getter. This tax rests on capital when applied to bank deposits or household goods, and on legal privilege when applied to shares in corporations owning land or patent rights.

XII. The General-Property Tax is a combination of taxes No. X and XI and has the same incidence and general effect. This still remains our favorite tax for local purposes; but, owing to the ease of evasion of No. XI, it operates in practice chiefly as a Real-Estate Tax.

XIII. The Income Tax in its simplest form may be a levy on labor, capital, or legal privilege, separately or in combination. In practice it is customary to exempt the incomes of manual laborers from the tax, so that any tendency it might have to lower the common standard of living may be avoided. Owing to the fact that the proportion of the national income produced by corporations is constantly increasing, the collection of this tax at its source renders its evasion at the present time much more difficult than it was half a century ago, when production was largely by individual entrepreneurs. Nevertheless, recent figures indicate that a large sum still evades the Federal assessor, and that many have enjoyed the premium for perjury that this species of taxation offers.

The surtax feature of the Federal Income Tax is designed to collect an extra sum from the larger incomes, on the theory that they proceed from investments rather than from the earnings of mental labor. But as no distinction is made between incomes that are obtained from the interest on true capital and those due to the rent proceeding from land ownership, the surtax is evidently a crude way of attaining economic justice. Moreover, this tax does not impede the speculation and monopoly

⁴'Natural Taxation', by T. G. Shearman, Chap. VI.

of natural resources, as no levy is made until cash profit is actually received.

The decision of the Supreme Court in 1920, which exempted stock dividends from the Income Tax, enables corporations to evade this tax in the same way as the land speculators. If this tax were to be permanent the result, in the long run, might not be far different for the evaders; but the latter are hoping—and lobbying—to abolish the whole idea long before they get ready to 'cash in' on their profits.

The existence of huge issues of public bonds which are exempt from the Income Tax forms another serious obstacle to proper functioning. Although the exemption may help to sustain the market price of such bonds, it is evidently a case of "paying too dearly for the whistle". Instead of abolishing the Income Tax, as is the proposal of the monopolists' lobby, would it not be wiser to change the law so as to withdraw all exemptions not specified in the bonds themselves? And in the last case, these special issues should be paid off, or refunded as soon as possible on a non-exempt basis.

XIV. The Excess-Profit Tax is a modification of the Income Tax designed in England during the Great War with the object of making the war-profitier 'divvy up' with the Government. As levied by our Federal government,⁶ it now takes 20% of the net income, beyond the excess-profits' "credit" and up to 20% on the invested capital, and 40% on any income above this 20% of the capital. As the "credit" exempted from the profits before this tax is levied amounts to a minimum of 10% on the invested capital, it evidently includes all normal profits. This tax may therefore be considered as affecting only extraordinary profits, or such as generally proceed from the ownership of legal privileges or the practice of monopoly. In unusual cases, such profits might be due to special ability in the management. Of course in war times a dazzling rate of profit for efficient plants often was due to the fact that the Government pursued the policy of paying excessive prices for commodities in order to encourage the operation of inefficient plants.

In spite of the present hue and cry against the Excess-Profits Tax, as tending to maintain the high cost of living, I can see nothing in the theory of taxation to warrant such a conclusion. As it is levied on the *residual* profit, after all the normal charges for labor and capital have been paid, it is analogous to a tax on land rent, which cannot, normally, affect the price of commodities. The other accusation that the operation of this tax tends to restrict the amount of private capital available for new enterprises is certainly true, but so would any other tax. Our government cannot withdraw four billions of cash annually from the savings of its citizens, and spend it on war debts or preparations, and expect the money market to remain unaffected by the operation.

XV. The Inheritance, or Estate, Tax, as newly levied by the Federation⁷ in addition to the same taxation long established in many States, varies in its rate—from 2%

for estates between \$50,000 and \$150,000, up to 25% on any surplus above \$10,000,000. This tax tends to fall on the privileges of land ownership or patent rights in its upper reaches, as few great fortunes arise from other sources.⁸ With its \$50,000 exemption for all resident testators, it does not affect a reasonable provision for natural heirs; and with its exemption of all bequests for public purposes it allows a testator to decide how his fortune shall be spent for the common good. It is an ideal tax for the purpose of extinguishing war debts; its chief fault lies in the lowness of its rates.⁹

Before 1912 the Budget was mainly derived from the Import and Excise taxes, both of which raised directly the cost of living. It is true that anyone could legally evade the latter tax by affiliating himself with the W. C. T. U., but few miners knew enough of either taxation or personal hygiene to achieve this happy result. Later, with the inauguration of the Federal Income Tax, part of the budget began to be derived from the incomes of the rich instead of from the wages of the poor, but it was not until the inauguration of war taxation in 1917 that the subject became of vital importance.

The extra three billions of revenue that we are now levying annually above the pre-war budget has been mainly derived from the Income, the Excess-profit, and the Inheritance taxes. The Import Tax has produced little, owing to the paralysis of European workshops, and the Excise Tax has been hard hit by the inauguration of national prohibition. Both of the latter taxes tend to raise the cost of living for the miner and consequently the cost of production for the operator, but the first three taxes do not affect prices, except in their influence on interest by lessening the quantity of private capital available for new enterprises; but this is a result produced by all taxation of savings, and there is no alternative but the taxation of wages in such a way as to reduce the general standard of living, thus causing disastrous social harm.

If the direct taxes, now yielding the main Federal income, are replaced by indirect ones like the tax on merchandise sales, it means more than the shifting of the burden of government from the shoulders of the coupon-clipping classes to the consuming masses, though that is bad enough. All taxes on consumption increase prices, not only by their face value but by an additional amount, sufficient to cover the interest and dealer's profit on the amount advanced. This addition is often greater than the tax itself and represents pure economic friction.

The most rational suggestion for improving Federal taxation seems to be the Ralston-Nolan bill, which proposes to tax the privilege of land ownership. By this plan, undeveloped lands, now almost free of the tax burden, would begin to contribute their quota, and land-speculation would be discouraged.

Flotation Practice at Mount Lyell

By L. V. Waterhouse

***INTRODUCTION.** The flotation plant at Mount Lyell was erected, primarily, for the treatment of copper ore from the Lyell Comstock mine. The erection of a plant was delayed by the general dislocation of business at the outbreak of the War, but finally it became possible to secure all the necessary machinery in Australia and to import motors. Operations commenced on February 17, 1916, with all the success anticipated.

The sulphides in the Lyell Comstock ore consist of chalcopyrite and pyrite, finely disseminated through a gray schistose gangue, usually decomposed. Bands of hard quartzite carrying sulphides also traverse the ore-body.

After operations were well established, trial lots of North Lyell silicious ore were put through the plant with such success that the mining department made arrangements to select underground in the stopes a lower-grade ore than the usual 6% smelting ore, to supplement the Lyell Comstock milling material, and finally it became possible to start a second shift. The North Lyell ore carries bornite, chalcopyrite, and pyrite in a silicious gangue, consisting mainly of a hard quartzite and some schist.

The following are typical analyses of the respective ores:

	Lyell Comstock	North Mt. Lyell
Copper, %	2.6	3.5
Silver, oz.	0.23	0.7
Gold, oz.	0.02	0.01
Silica, %	46.0	66.0
Iron, %	11.5	8.0
Barite, %	1.4	2.0
Alumina, %	15.5	7.7

For the year ended September 30, 1919, concentration results were as follows:

	Tons	Copper, %	Silver, oz.	Gold, oz.
Lyell Comstock	13,595	2.18	0.2	0.028
North Mount Lyell	14,873	4.74	0.88	0.008
Total ore	30,468	3.43	0.54	0.018
Concentrates	8,622	10.95	1.47	0.047
Recovery		90.41	77.70	72.41

COARSE-CRUSHING. Ore is received from the Lyell Comstock mine in self-discharging hoppers of 10 tons capacity (159 cu. ft.). Six trucks make up an ore-rake, which is hauled by 10-ton Krauss locomotives of 60 hp., the tractive force being 6490 lb. This ore is received on three days per week at the rate of 120 tons per day. The ore from the North Mount Lyell mine is drawn in 1½-ton trucks from bins at the top of the main Mount Lyell haulage. All ore is weighed on the main smelter Pooley 75-ton weigh-bridge. On account of limited bin accommodation, the ores are inadequately mixed, and consequently treatment has to be constantly varied as required by the different classes of ore.

*From the Proceedings of the Australasian Institute of Mining & Metallurgy, No. 33.

The crude-ore bin is lined with discarded manganese-steel crusher-jaw faces, and the only attention required is the occasional renewal of steel lining-plates on the face of the bin.

An old Krupp crusher of the Blake type was utilized, with cast-iron body in a single piece. The back toggle was made a shearing toggle with twelve 1 in. rivets. Imported Sheffield manganese-steel jaw-faces have an average life of 6100 tons of ore crushed, against 4500 tons for Australian manganese-steel. The latter have shown large variations in quality, though the manganese contents are similar, probably indicating irregularities in the heat-treatment. The crusher is driven at 240 r.p.m. by a 9-in. camel-hair belt, and set to crush to 2 in. A fine water-spray is provided immediately above the jaw opening, to allay dust.

At the outset, considerable difficulty was experienced in wet weather in extracting Lyell Comstock ore from the crude-ore bin on account of its 'puggy' nature, its moisture at times reaching 10%. This was overcome by making an enlarged door opening, 4 ft. 3 in. long by 1 ft. 9 in. high, with a radial door 3 ft. 10 in. long, and sluicing the ore in the bin with just sufficient water to form a slurry of the fine. The coarse ore discharges readily from the end of the conveyor into No. 2 fine-ore bin, while the slurry adheres to the conveyor belt, passes around the delivery drum, and is scraped off into a launder that delivers to the 'raff' elevator. It is thus immediately eliminated and treated. The adoption of this 'wet system' has rendered it possible to handle this class of ore without the least difficulty or loss of tonnage, and is an important factor under local conditions.

FINE-CRUSHING. Ore is delivered to the screens from the fine-ore bins, which are fitted with ratchet-doors, by means of corrugated roller-feeders, and the undersize is thereby eliminated before roll-crushing.

The screens are of the Broken Hill North type. Perforated steel plates, with holes either 7/64-in. diam. by 0.194-in. centres by 16 gauge, or 1/4-in. diam. by 0.22-in. centres by 14 gauge, are used. They have an average life of 2150 tons of crude ore screened. Soluble copper from the Lyell Comstock open-cut at times materially reduces the life of the screen-plates. The connecting-rods are built up of three plies of 4-in. by ½-in. ash, with ¼-in. plate cover. The screen is set at a 5° slope, and half the screen is below water-level. The power required is about 2 hp. each. Holes are bored in the screen-boxes, so that surplus water overflows into the iron-lined chutes, leading to the rolls. The undersize passes out of the screen-box through a 1½-in. diam. wooden plug, and the discharge averages 25% solid.

The oversize passes through the rolls, then is elevated

by the 'raff' elevator back to the screens. The flanged roll is belt-driven by 11-in. camel-hair belting, and the plain roll is gear-driven through twin wheels, the speed being 21 r.p.m. Chrome-steel roll-shells have a life of 9000 tons of ore crushed, against 5100 tons for carbon-steel shells.

The screen undersize is elevated in the 'fines' elevator and passes through the sampler to a diaphragm-cone classifier and dewaterer with an automatic regulator, as in Fig. 1.

The sliding weight requires adjustment for the two ores, greater leverage being necessary for that of North Mount Lyell. An arrow attachment in a prominent position serves to indicate the position of the east-iron plug,

FIG. 1

and is useful in detecting irregularities, which are very rare, as the regulation is almost perfect. The cone discharge averages 26% moisture. The plugs have a life of four months and the suspension-rods two months.

The following are typical tests on the cone products:

Mesh.	—Lyell Comstock—			—North Mount Lyell—		
	Feed.	Spigot.	Overflow.	Feed.	Spigot.	Overflow.
I. M. M.	%	%	%	%	%	%
+ 20	47.7	92.2	...	63.6	65.9	...
+ 40	11.1	12.6	...	12.3	15.0	...
+ 60	7.1	5.5	...	4.2	5.8	...
+ 90	6.8	10.2	...	4.2	4.5	0.36
+ 120	5.5	1.2	2.5	3.9	2.8	1.1
+ 150	3.7	0.1	3.8	1.1	0.8	1.2
— 150	14.8	1.9	93.7	10.7	5.2	97.34

TUBE-MILLING. On account of the limited room available for the plant, gear-driven tube-mills were adopted. These are driven by 75-hp. motors, and have flexible couplings on both rotor and counter-shafts. For the purpose of standardizing motor-speeds generally in the plant, 750 r.p.m. motors were used, but this high pinion speed cannot be recommended. 'Fabloil' pinions have a life of about five months, but better results are obtained

with locally-made phosphor-bronze pinions, run in an oil bath, in which case phosphor-bronze bearings are used on the rotor-shaft. The mills are run in both directions of rotation, thereby extending the life of pinions and inside liners.

The mills are 16 ft. long by 5 ft. diam., with a hollow trunnion bearing on the feed end, and a forged-steel tire 2 ft. 9 ⁵/₁₆ in. diam. running on east-steel rollers on the discharge end. The shell is built in three sections, bolted together by means of heavy angle-irons. The east-iron liners, which are ribbed, are made locally, and have a service of about 25,000 tons. The wear on the end liners, which are also ribbed, is more severe, and these are replaced individually as required.

The mills are equipped with scoop-feeders with a radius of 12 ⁵/₈ in., and through these the daily charge of pebbles is fed. Owing to the irregularity in supply and

FIG. 3

quality, and also the high cost of flint pebbles, Tasmanian quartzite pebbles are now used. These average 2 ¹/₂ to 4 in., and the consumption amounts to 11 lb. per ton of ore.

Fig. 2 shows the general arrangement of a tube-mill.

The following tests exemplify the work of the tube-mills:

Mesh.	Lyell Comstock		North Mount Lyell	
	Feed.	Discharge.	Feed.	Discharge.
I. M. M.	%	%	%	%
+ 20	92.2	...	65.9	...
+ 40	12.6	2.1	15.0	2.4
+ 60	5.5	6.2	5.8	6.9
+ 90	10.2	15.4	4.5	13.0
+ 120	1.2	8.7	2.8	8.1
+ 150	0.4	3.1	0.8	5.1
— 150	1.9	64.5	5.2	64.5

The moisture averages 26%, namely, that of the cone-spigot product; and the rise of temperature is 18°, from 56° to 74°F.

DORR THICKENERS. Two Dorr thickeners take the overflow from the diaphragm-cone classifier, and are of the standard design for 20-ft. diam. tanks. No overload

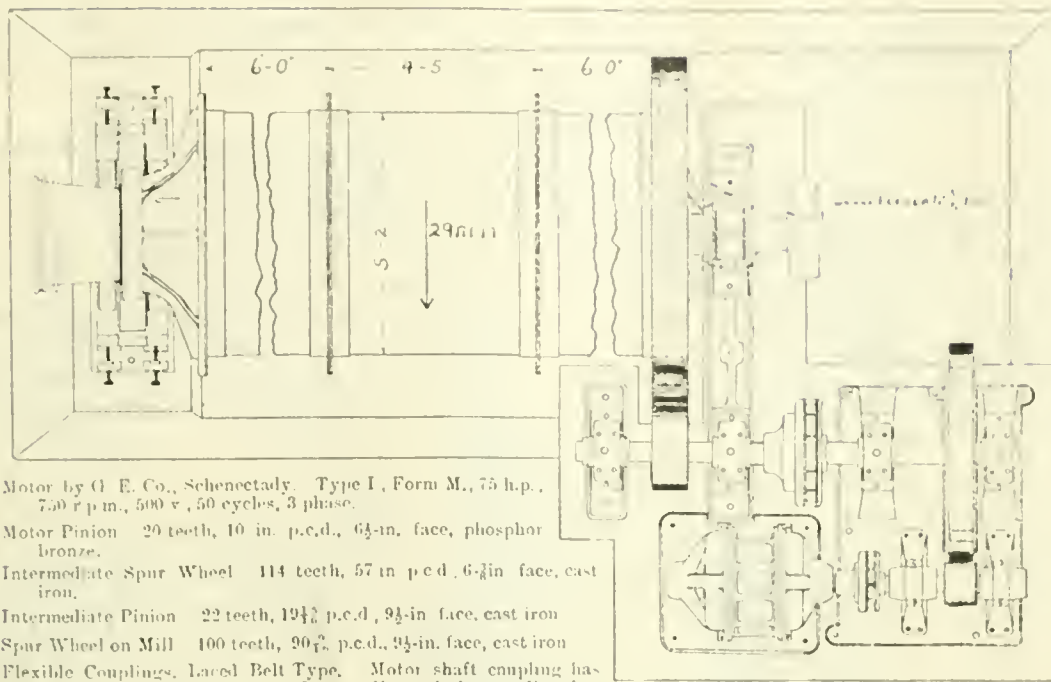

FIG. 2. ARRANGEMENT OF TUBE-MILL

FIG. 5. DETAILS OF SAMPLE-FILTERS

alarm is used, and an examination of the spring at starting is all that is necessary. The speed is $\frac{1}{2}$ r.p.m., and the discharge averages 40.0% solid.

The tanks are of steel construction, with $\frac{3}{8}$ -in. shell and $\frac{1}{4}$ -in. bottom. Gate-valves on a 4-in. pipe regulate the discharge.

The feed is laundered into a wooden box, 2 ft. square by 1 ft. deep, with a central pipe 8 in. diam. that extends 12 in. below the surface, covered by a screen to collect chips, etc. A diving-ring, 30 in. diam. by 48 in. deep, of $\frac{1}{8}$ -in. plate, concentrically surrounds this pipe and prevents any surface eddies.

FLOTATION. The tube-mill and thickener discharge join in the boot of the feed-elevator, which delivers to a

phragm-cone discharge before being split between the two mills, and eucalyptus oil to each tube-mill through $\frac{1}{4}$ -in. pet-cocks from pipes connected to a supply-tank. The consumption of tar is 0.1 lb. and of eucalyptus oil 0.8 lb. per ton of ore.

Compressed air is introduced immediately under No. 1 stirrer in limited quantity, and tends to produce a crisper float on the first boxes.

The float from the last four spitz-boxes is returned as a middling to the feed-elevator.

The dilution of the flotation boxes is maintained at about $4\frac{1}{2}$:1. On account of the difficulty in settlement of the slimed gangue of the Lyell Comstock ore and its tendency to sicken the float and lower the grade of con-

FIG. 4. SAMPLE-REDUCER

balance cone, 2 ft. 6 in. diam. by 3 ft. 6 in. deep, at the head of the flotation boxes. Pebble fragments that escape the grating of the tube-mills are caught on a screen at the elevator boot.

The main flotation unit is of the standard Minerals Separation type, and contains 12 agitation and spitz-boxes. The agitation boxes are 2 ft. 3 in. square by 3 ft. 10 in. deep, and have cast-iron liners. The stirrers are four-bladed, 19 in. diam., revolving at 320 r.p.m., driven by a $\frac{1}{4}$ twist-drive of four-ply 4-in. Balata belt, and the 2-in. shafts are equipped with S.K.F. radial and thrust-ball races. The line-shaft, which is 4 in. diam., is equipped with five S.K.F. ball-races and driven by a 75-hp. motor with 14-in. camel-hair belting. Two-bladed paddles, revolving at 19 r.p.m., are provided for skimming off the float at the lip of the spitz-boxes.

The addition of frothing media is made to the tube-mill feed, with such additions as may be necessary at the flotation boxes, generally only at starting up, until the thickener flow is normal and regular conditions are obtained. A mixture of one part of eucalyptus oil to two parts of coal-tar is fed by a disc-feeder to the dia-

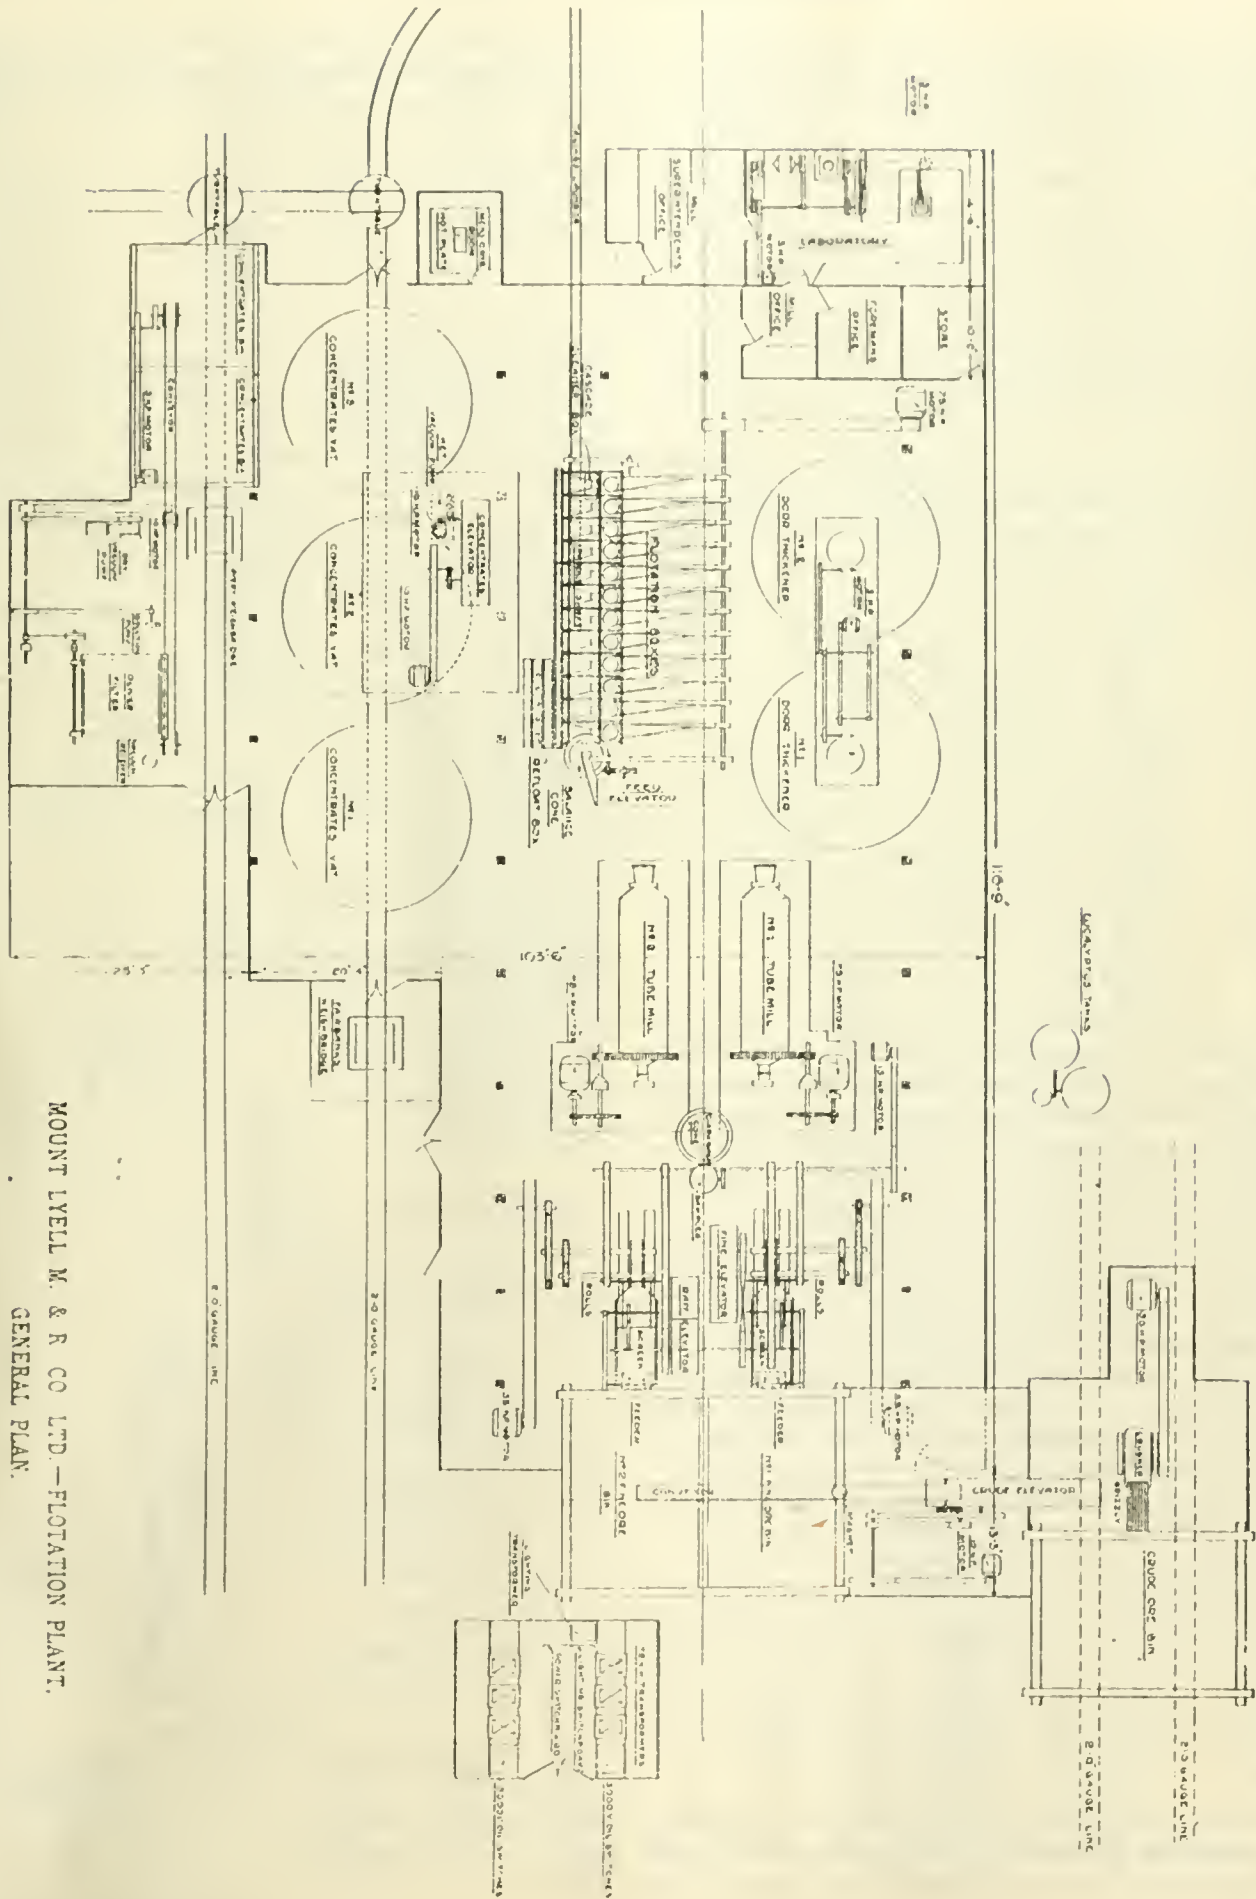

centrate, the flotation section is arranged in open circuit, that is, there is no return tailing-water.

Sulphuric acid is not found to be necessary in the treatment, although indicated in the experimental investigation of North Mount Lyell ore. The improvement in the grade of concentrate by the use of acid is offset by the drop in the recovery.

The flotation solutions are not heated, but conditions improve with a rise in temperature. The temperature of solution varies from 47° in winter to 74°F. in summer.

As the height of the discharge from the flotation boxes above the tailing-launders was sufficient to place a single cascade-box, a unit, as shown in cross-section in Fig. 3, was subsequently installed. This box acts as a tailing-seavenger and returns some pyrite as a middling, and at the same time is a guide in the operation of the flotation boxes, as it indicates changes in dilution and irregularities in the float.

A separate flotation unit, the subject of my Australian patent 2353/16, was installed to re-treat the concentrate from the M. S. flotation boxes. It consists in forcing

MOUNT LYEEL M. & R CO LTD.—FLOTATION PLANT.
GENERAL PLAN.

The drum is wound, over the canvas, with 11-gauge copper-clad steel wire, the turns being about $\frac{1}{2}$ in. apart. It takes about 16 hours to re-canvas and re-wire the drum. The canvas lasts about eight months, and the hessian under the canvas two years. One recent canvas handled 5157 tons of concentrate. The canvas is occasionally hosed and scrubbed. The scraper requires particular attention, and is periodically filed, reversed, or renewed.

The air-lifts and emergency air-agitation pipes were not found satisfactory, and were discarded. The speed of the mechanical agitators was increased to 74 r.p.m. The original agitator-shaft consisted of a heavy 3-in. pipe flanged to stub-shafts on each end. It was soon found necessary to use a solid 3-in. shaft. Wrought-iron paddles, 9 in. apart, and placed alternately to right and left to avoid thrust, have been used, but, on account of the presence of copper in solution, cast-iron paddles are now being tried.

The attendant on the flotation boxes also operates the filter, which requires a minimum of attention.

The filter delivers the concentrate onto an 18-in. inclined conveyor, which, in turn, delivers to the bin.

The concentrate is loaded into $\frac{3}{4}$ -yd. Bochum trucks, and drawn to the smelter, distant about 200 yards, by horse.

SAMPLING. The feed sample is taken in the fine-crushing section by a sampler developed on the Broken Hill South mine, consisting of two inverted hollow cones, rotating on the same axis in opposite directions at different speeds, and having knife-edge cuts through them at different radii from the above axis.

Grab-samples are taken of concentrate and tailing at regular intervals for daily record. Filtered concentrate is officially sampled as dispatched to the smelter by means of cheese-samplers.

The pulp-samples are reduced in the machine shown in Fig. 4. The reducer is made in three parts for the purpose of cleaning and inspection.

On account of the difficulty in settlement of slime and the distance of the assay-office from the plant, filters for samples were devised, and have proved useful. Fig. 5 shows the arrangement and general details.

ELEVATORS are framed of 6 by 3-in. Oregon pine with 6 by $\frac{1}{2}$ -in. pine lining. The width between lining is 2 ft. 2 in., and the depth 6 ft. All top and bottom drums are 36 in. diam. by 15-in. face by $\frac{5}{16}$ -in. crown by 4-in. shaft, with ring oil-bearings on top and solid bearings with brass bushes on the bottom.

All belts are 8-ply Balata, 12 in. wide, and driving-belts 6-ply Balata, 6 in. wide. Buckets are riveted mild-steel plate; they weigh $7\frac{1}{2}$ lb. and have 190 cu. in. capacity.

Sand-guards are provided on the bottom shaft, a deflecting saddle, at 45° above the drum, carrying rubber scrapers, and adjustable lips at the discharge. The centre of the top drum is 3 ft. 9 in. above the discharge lip, which gives a satisfactory delivery at the speeds employed.

The belts for elevating the feed and concentrates have been running for four years without renewal. The belt that elevates the crude ore has the most severe duty, and lasts about 35 weeks, or 23,000 tons, against 58,000 tons for the raff-elevator, and 41,000 tons for the fine-elevator.

The sulphide of cadmium is a brilliant pigment, states a U. S. Geological Survey bulletin. If properly prepared it is one of the most permanent pigments known, and is unaffected by hydrogen sulphide gas from coal smoke, whereas the common yellow pigments are blackened in a smoky atmosphere. Cadmium-yellow is therefore employed as a protective coating over chrome-yellow in painting street cars and the passenger coaches on some railway lines. Sulphide of cadmium is used extensively to give color and lustre to glass and porcelain; other cadmium salts are used in dentistry, dyeing, and photography. The so-called cadmium lithopone, which is analogous to lithopone and in which cadmium replaces the zinc, has been experimentally known for some years. Hanley says: "It is believed that the pigment industry offers a good prospective field for the consumption of cadmium compounds. Cadmium-yellows and cadmium lithopone constitute the principal forms used, and the persistence of the color is a favorable feature of these pigments. They can therefore be used advantageously in an atmosphere vitiated with sulphur smoke, whereas the chrome-yellows darken under similar conditions. Cadmium has long been used by artists who require beautiful and persistent yellow or orange tints. The sulphide, which is the form used in paints, will stand considerable dilution with a transparent thinner, such as heavy spar, without losing the intensity of the yellow color. It may be possible, therefore, to develop a color using this pigment that could compete in price with cheaper yellows. This proposition would require development by experienced paint chemists in order to be definitely established. The shade of color can be accurately controlled from light yellows to deep vermilions by regulating by hydrogen sulphide the acidity of the cadmium sulphate solution from which it is precipitated. Consequently the color required by the trade could be consistently duplicated." Cadmium electroplating is a field that offers some promise of expansion. Cadmium is a better rust preventive than nickel, and at more nearly a parity in prices cadmium plating might be substituted for nickel plating on some articles. Or, as it has a greater tendency to tarnish than nickel, it might be used in combination with nickel, the first coat consisting of the rust preventive cadmium and the second coat of the tarnish-proof nickel. The Udylyte Process Co., of Kokomo, Indiana, has developed a commercial method for electroplating iron and steel articles with cadmium and is prepared to grant licenses for its use.

The greatest depth yet found in any ocean is 32,088 ft., at a point about 40 miles north of the island of Mindanao, in the Philippine Islands, states the U. S. Geological Survey.

Factors in the Production of Iron and Steel on the Pacific Coast

By Clyde E. Williams, Metallurgist, U. S. Bureau of Mines

*The question of the establishment of an iron and steel industry on the Pacific Coast has been the subject of discussion and investigation for many years. Such an industry is necessary if the West Coast is to develop and make the most of its wonderful natural resources. The cost of shipping iron and steel products from Eastern points to the Pacific Coast increases their cost one-half if shipped by water and two-thirds if shipped by rail. This same relation held before the War, when the cost of iron and steel and transportation rates were both lower.

Admittedly, cheaper iron and steel are needed. Whether these can be obtained by producing them upon the Pacific Coast depends upon a number of factors. Chief among these are: (1) the supply of raw material; (2) the amount and nature of the market; (3) the size and type of smelting operation.

COKE. The vital factor in successful blast-furnace smelting is coke. Iron ore can be brought from great distances cheaply, but it is costly to transport coke. Coke represents one-third of the weight and one-half of the volume of the ordinary blast-furnace charge. Normally from 20 to 30% of the cost of production is due to coke. There are two outstanding characteristics that the coke must have. First, it must be cheap, and, second, it must have the mechanical strength to support the weight of the charge and sufficient hardness to resist too rapid solution by the ascending gases.

There are several coals of good coking quality in the State of Washington. These coals are high in ash and must be washed before being used in the coking process. Even with careful washing, however, the best coke that can be made from these coals contains 15% or more ash. Perhaps the best supply of coking coal for the present consideration is that in the Wilkeson-Carbonado-Fairfax district in Pierce county. Coke made from this coal has suitable physical properties and is sufficiently low in sulphur and phosphorus to be desirable for use in the blast furnace. Its high ash-content will make necessary the use of more coke than is ordinarily the case, and hence the cost of smelting will be greater. There is some coal in this district whose content of ash can be lowered by washing to 7.5%. Coke made from this product would contain only 12% ash. Unfortunately, however, this coal is said to be non coking.

There are coking coals in British Columbia at Cassidy and Cumberland on Vancouver Island, and in Nicola valley and Crows Nest Pass on the mainland. A coke is being made in by-product ovens at Anyox by mixing the

high-volatile coal found at Cassidy with the low-volatile coal obtained elsewhere. It is said that this coke has suitable physical properties for use in the blast-furnace. The ash-content is high and it is doubtful if any coke can be made from British Columbian coals that will be lower in ash than that made from the Pierce County coal. Indications are that the ash-content will be higher.

A large quantity of coking coal has not been developed in Oregon. It is said, however, that the Eden Ridge (Coos county) coal is of coking quality.

California has no coking coal. Utah coke of excellent physical qualities and low ash is available, but only after a long rail-haul that approximately doubles the cost of the coke.

From the above information it is evident that coke is available in British Columbia and in Washington, that this coke is suitable for blast-furnace use, and that its cost will be more than the cost of coke in Eastern districts because of its high ash-content and the higher cost of mining it. Coke should not be moved great distances, and Utah coke should not be shipped to California. The smelting centre should be near the coke-supply in British Columbia or Washington.

IRON ORE. The presence of iron ore near the smelting locality is not so important as is the presence of coke. Iron ore can be shipped as ballast cheaply from great distances. No large deposit of iron ore is found in Washington. However, if a smelter were established in the North-West, the many small deposits would undoubtedly be drawn upon.

Magnetite occurs in British Columbia on Texada, Louise, Redonda, and Vancouver islands, and on the mainland to the north of these islands. Some of these deposits contain as much as 60% iron and some only 50%. In some instances, the content of sulphur and copper is so large that the ores must first be purified; in others, no pre-treatment is necessary. A large tonnage of these ores is said to be available, but their true extent and composition will only be determined when a market has been established and large-scale mining operations are carried out.

There is a vast supply of high-grade hematite ore in southern California in the Eagle mountains, of Riverside county, and in the Cave Canyon district and in the Providence mountains of San Bernardino county. These ores are rather far inland, but fortunately not far from a railroad. It is probable that other ores nearer tide-water can be obtained at less expense.

Large supplies of high-grade hematite occur in Mexico, the most accessible to the Pacific Coast being those on

*A paper presented at the International Mining Convention at Portland, Oregon, on April 7, 1921.

the west coast of Lower California at St. Vincent. Other deposits in Mexico near the west coast are in the States of Guerrero, Michoacan, and Oaxaca. These ores could be brought to the North-West on returning ships that carry lumber to the Southland. In the same way, the rich Chinese ores could be brought over on ships that carry goods from Pacific Coast ports to the Orient. If this country is to engage in a profitable export business with the Orient, our ships must not return therefrom without cargoes.

Summarizing the facts, sufficient ore of good quality can be brought to an iron smelter on the Pacific Coast; the rich ores of the west coast of Mexico and of China offer the greatest potentialities; the magnetites of British Columbia are available at tide-water, and the hematite of southern California can be obtained at tide-water after a rail-haul of about 200 miles.

LIMESTONE. The limestone at Roche Harbor, on San Juan island, that near Blubber Bay, on Texada island, and that near Cape Flattery, on Vancouver island, are available for use in the Puget Sound region. Sufficient limestone to maintain a plant in southern California may be obtained in San Bernardino county.

REFRACTORIES. Clay for refractory purposes is available at Clayburn in the south-western part of British Columbia, just across the line into north-western Washington at Sumas; also at Clayton, and Freeman, near Spokane, and at Moscow and Troy, both in Idaho. That at Clayburn is now being made into good firebrick and that at Sumas can be mixed with Kummer (Washington) flint, an excellent brick being obtained.

MARKET. Much difference of opinion exists as to the scope of the market for iron and steel on the Pacific Coast. It is difficult to obtain reliable data. The customers are scattered over such an extensive area, and their purchases are so variable in amount and kind that it is almost impossible to obtain information from them. Those whose purpose it is to promote the establishment of an iron and steel industry on the Pacific Coast, such as Chambers of Commerce and similar organizations, are prone to be too enthusiastic. Their quantities are usually several times too large. On the other hand, the iron and steel corporations, when asked to establish such an industry, will quote statistics that are much more conservative, perhaps more nearly representative of the conditions, but undoubtedly on the smaller side of the scale. However, in this discussion the important factor is not so much what the present consumption is but what the consumption would be if cheaper iron and steel were available.

No pig-iron is produced on the Pacific Coast. Most of that used comes by rail from the East. Small amounts arrive from time to time from China and occasionally from Great Britain and elsewhere. Two hundred tons of pig-iron is consumed daily, practically all of it being used for making gray-iron castings. With cheaper pig-iron the present output of castings will be increased, and thus the market for foundry iron will become larger.

The production of steel in California, Oregon, Wash-

ington, and Utah is 1000 tons per day. Scrap-iron and scrap-steel are used almost entirely because they are cheaper than pig-iron. Cheap pig-iron would replace a large portion of this scrap. The steel-makers would like to use part pig-iron in the charges to the furnaces because at times scrap is hard to get, its cost increases with the demand, and a mixture of part scrap and part pig-iron is more desirable from the standpoint of melting.

Although the total consumption of steel on the Coast is large, it consists of many different sizes and shapes, without a large continuous consumption of any one. Steel rolling-mills are complex and expensive and to be operated profitably must have a large production. It would be impossible to construct and operate a mill to produce so large an assortment of sizes and shapes on the small scale necessary to prevent flooding the Pacific Coast market. Those products must be made for which there is a large steady demand or which can be made by the same machinery. An example of a product for which there is sufficient demand to take the output of a modern rolling-mill is tin-plate. The consumption of tin-plate and tin-cans in California, Oregon, Washington, British Columbia, and Alaska amounts to 150 tons daily, and the amount exported through Pacific ports to 100 tons. Hence, a market exists for 250 tons daily, and it is reasonable to suppose that a portion of this market could be absorbed by a producer on this coast.

The market for steel products will grow as the West grows; each will help the other. At the present time, however, there is little opportunity for the development of a large steel industry. The development to be anticipated will come through the slow and substantial growth of the present producers, increasing their output and developing new products (such as tin-plate) for which there is a sufficient market.

Pig-iron produced on the Coast, if cheap enough, will be used by the foundries for making gray-iron castings and by the steel works as a partial substitute for scrap-iron and scrap-steel. The amount of pig-iron that will be consumed will depend upon its cost. There is sufficient outlet through these two sources for the output of one blast-furnace of about 400 tons capacity. A cheap source of pig-iron once established, new industries will spring up, consumption of iron castings and steel products will increase, and thus a larger production of pig-iron will gradually become possible.

Japan is expanding her steel industry rapidly. Not sufficient ore is found in Japan, so ore and pig-iron are being brought to Japan from China. The production of iron and steel is now between 550,000 and 750,000 tons per annum. The consumption is between 1,500,000 and 2,000,000 tons per annum. Japan, therefore, will be an importer of American iron and steel products for some time. However, her industry is expanding so rapidly that the time is coming when she will be able to take care of herself. Whether this expansion will become great enough for Japan to export to America and therefore compete in the Pacific Coast States is questionable.

Much has been said in the past regarding the importa-

tion to this country of cheap Chinese pig-iron. It is true, Chinese pig-iron has been laid down on the Pacific Coast for less than pig-iron from eastern United States could be. But there is no danger of any great competition from this source. The so-called cheap Chinese labor is not cheap when reduced to terms of output per dollar. Coke is available in China, but it is expensive. Considering all things, the cost of producing pig-iron in China is comparatively high; and China, rather than engaging in the production and exportation of iron, will become an active consumer, particularly of steel products.

Another factor entering into a discussion of markets is the attitude of the Eastern producer. In order to hold

County coke. The determination of the cost of production is a difficult problem. It can be done best by experimentation. This would be costly and should be attempted only by those with the true pioneering spirit and with sufficient financial backing to be able to withstand great losses. In the beginning, costs of operation will be high, and unforeseen difficulties will arise. Absence of profit during the early days of operation must be anticipated. The most advantageous site for the plant is in the Puget Sound district.

Electric smelting has been suggested as a substitute for the blast-furnace for the following reasons: (1) Good coke is not essential and the quantity of fuel needed amounts to only one-third that needed in the blast-furnace; (2) small-scale production is possible; (3) there is cheap power, or at least cheap potential power along the Coast. Were all these reasons facts, electric smelting would be a possible substitute. But power is not cheap, at least from the standpoint of electric pig-iron, and will not be cheap for many years to come.

Another process has been proposed, a substitute for both the blast-furnace and the electric-furnace processes and a sort of combination of the two. It is the preparation and melting of sponge-iron. Briefly, the process consists of grinding and purifying the ore by magnetic concentration, mixing it with a low-grade fuel, heating for two or three hours at a temperature of about 950°C., cooling, and passing the mixture through a magnetic separator. Metallic iron in a very finely divided condition, free from impurities, is obtained in the concentrate. This product is called sponge-iron. It is then melted in the presence of carbon in an electric furnace, by which means various grades of iron and steel can be made at will. From a theoretical standpoint, this process has some promise. It will utilize fuel of poor quality and can be used with impure ores. The fact that various grades of iron and steel can be made makes it adaptable to the conditions existing on the Pacific Coast. For example, to large centres that have near them deposits of iron ore and cheap fuel and that consume both foundry iron and steel ingots, this process would be peculiarly adapted. Sufficient experimentation has not been done to point to either success or failure.

CONCLUSION. The establishment of an iron and steel industry must not be undertaken without due consideration of all the relating factors. We need cheaper iron and steel; we have the raw materials at hand; we have only to determine the cost of production. The cost of production will depend upon the cost of coke, the size of the market, and, hence, the size of the metallurgical operation. The size of the market will depend upon the cheapness of the pig-iron and upon the number of different steel products that can be made profitably in the rolling-mill. The presence of such an industry will stimulate the growth and development of the West. The determination of the cost of production can, and undoubtedly will, soon be made, but it must be done by a strong organization and one with a fund of advice, both technical and commercial.

his present market on the Pacific Coast, he will fight any competitor on the Coast by cutting costs. On some products it is likely that the reduced cost will be comparable with the cost of production on the Coast. This, of course, would reduce the possible output and make the project still more precarious.

SMELTING PROCESS. The size and type of smelting operation depends upon the size and the nature of the market. If there is a large enough outlet for pig-iron, the blast-furnace process will be used, because it is the standard, and, of course, the cheapest. The high cost of coke and the fact that the market for pig-iron extends over the vast area of the Pacific Coast States may make the cost of production of iron so large that the present margin due to the high cost of transportation will be eliminated.

Statements have been made by engineers that pig-iron can be made as cheaply on this Coast as in the East. C. C. Jones of Los Angeles showed by calculation that this could be done by bringing coke into southern California from Utah. Others have suggested that this could be done in a plant in the Puget Sound region using Pierce

REVIEW OF MINING

DIVIDENDS FROM UTAH MINES DURING 1921

During the first six months of 1921, metal-mining companies in Utah distributed dividends to their stockholders as follows:

Chief Consolidated Mining Co.....	\$88,403
Grand Central Mining Co.....	6,000
Gold Chain Mining Co.....	10,000
Silver King Coalition Mines Co.....	182,415
Tintic Standard Mining Co.....	117,470
Utah Copper Co.....	2,436,735

Total\$2,841,023

During the first six months of 1920, ten metal-mining companies in Utah paid dividends totaling \$5,754,071, and for the corresponding period in 1919, a total of \$5,565,579 was disbursed. The dividend paid by the Silver King Coalition was the first in four years. The other disbursements, by the Chief Consolidated, Tintic Standard, and Utah Copper companies, all represent large decreases from former years.

SENATOR W. A. CLARK ON THE COPPER OUTLOOK

W. A. Clark, ex-Senator from Montana, is quoted as saying: "The copper market right now is about the flattest thing I know of, but it will not remain that way. As soon as things get straightened out in Germany there will be a big demand for copper all over Europe. We could sell copper now, but would not get the price of its production, and I will not sell it that way. Others feel the same, and we have formed a pool in this country of \$40,000,000 to protect the interests of copper producers, who have something less than a billion pounds of it ready for the market. This does not mean, however, that the mines will remain shut-down until all of this is disposed of. Just as soon as there is a demand and the product starts to move, the mines and smelters will begin active work again. I imagine it will be nearly a year before things get to going full-blast again".

CURRENT OPERATIONS OF THE A. S. & R. CO.

The American Smelting & Refining Co. has cut its operations to approximately 40% of normal. Notwithstanding the general curtailment in copper production, this company has closed but two of its copper smelters, the others operating at part capacity. The lead-plants are doing relatively better. From its own ores the smelting company is producing about 3000 tons per month, as against a normal of between 6000 and 7000 tons. In addition, it has been treating toll ores from other properties, some being regular shippers, while others have switched their product to the Guggenheims because of the shut-down of other plants.

The smelting company has succeeded in disposing of all its own 1921 copper since the first of the year, at which time it abandoned its selling agency. It has on hand, however, a substantial quantity of the metal which was brought forward from 1920 and which represents the unsold accumulation of the former agency. Two Mexican smelters have closed down, the others working part capacity on copper and

silver-lead ores. The El Paso copper smelter has gone cold, but the lead-furnace remains in operation. The Hayden smelter, handling Ray Consolidated concentrate, has also closed. The big Garfield smelter, however, continues to run, partly on Utah concentrates which have not yet been cleaned up, and to some extent on ores shipped from California, principally concentrate from the Engels mine. The Tacoma refinery has sufficient material from Kenecott, Beatson, and Britannia ores and from South American blister to keep it going at part capacity. The Perth Amboy copper smelter and refinery have been closed for some months, but the plant still operates on tin concentrates. The Baltimore refinery handles whatever copper comes to the East for treatment, while the rolling-mill department has continued operations at about 40% capacity.

WARRANT ISSUED FOR ARREST OF GEORGE GRAHAM RICE, PROMOTER OF BINGHAM GALENA COMPANY IN UTAH

George Graham Rice, alias Jacob S. Herzlg, whose name has been mentioned many times in connection with stock promotions in various parts of the country, was one of the group for whom warrants were sworn out in Oakland, on July 8, on the charge of violating the Corporate Securities Act of California. A warrant also was issued for John Doe, an unknown employee of Child, Barclay & Co., and a third warrant was issued for that company, a firm of stockbrokers in Salt Lake City.

A circular letter sent out by Child, Barclay & Co. is quoted as saying:

"We have been requested by George Graham Rice, now sojourning in Salt Lake, to place your name on our mailing list to receive from us a copy of the forthcoming issue of our weekly market-letter, which will contain an analysis of the merits of the Bingham Galena Mining Co. stock. We shall be glad to send you an early copy.

"Mr. Rice asks us to say that he believes an investment made in Bingham Galena stock at this time will, in all probability, make up any loss which you may have incurred in Broken Hills stock. The Broken Hills situation is so discouraging that he is unable to hold out any hopes to you of an early improvement in the market price of that stock, and he feels that he owes it to you to put you in immediate touch with the situation in Bingham Galena stock. He is anxious that you make up your loss as quickly as possible. Mr. Rice is behind the Bingham Galena company and we need hardly acquaint you with his constructive methods. Mr. Rice asks us to say that he believes the stock will enjoy a quick rise to well above 75c. per share and will later sell as very much higher figures. We invite your business in the stock and would be glad to hear from you without delay."

At the close of business on July 7, the stock in Salt Lake City had been pushed up to a price of 38c. per share, but on receipt of the news of a warrant for Rice's arrest on July 8, the stock broke to 17½c. per share.

E. C. Bellows, Commissioner of Corporations for California, is quoted as saying:

"The notorious George Graham Rice is once more at his

old tricks, and is reaching after gullible investors in California by unlawfully offering the Bingham Galena Mining Co. stock for sale through circular letters to unsuspecting dupes in this State. Assisted by the postal authorities, I hope to be able to extradite this public plunderer and bring him back from Utah to answer to the charge of violating the blue-sky law by offering stock for sale without a license."

CANADIAN COPPER PRODUCTION IS 52% OF 'NORMAL'

The slump in the market quotations for copper has affected Canadian production less than it has that of the United States. Today the Canadian production is 52% that of the 1920 total at the corresponding time, while the output of the United States is figured at 20% that of 1920. In 1920 the United States produced 36,000,000 lb. of copper monthly while Canada produced 4,600,000 lb. Practically the whole of the Canadian production came from British Columbia, the output of Ontario being confined to that obtained as a by-product from nickel ores. The Granby Consolidated Mining & Smelting Co. is reported to have had the biggest month of its history in point of production in May. The output ran to 91,000 lb. The recent fall in the market, following signs of a rally, has again started speculation as to the immediate future of the industry in this Province. It is possible that a further decline of a point or two would mean the closing down of the Anyox plant although it is explained by the management that this would be done as a last resort. There are 1150 men employed at the smelter centre at present and a considerable number at the Cassidy (Vancouver Island) Collieries which are operated by the same company and from which coal is secured for industrial uses at Anyox.

ARIZONA'S MINES ARE APPRAISED AT \$400,000,000

Producing mines in the State of Arizona are valued at \$413,982,735, or 9% less than a year ago, in a report just made public by the State Tax Commission. The valuation placed on producing mines in 1920 was \$453,094,846.26. "In view of the times, we consider a loss of only 9% a good showing," declared Charles R. Howe, chairman of the Commission. He said that the total assessment on mines will be more than one-half of the assessment on all property in the State.

The valuation of non-producing mines will be fixed by county assessors, but today it was estimated that this sum would be approximately \$10,000,000. Last year the valuation placed on non-producing mines was \$8,786,621.26. According to the Commission, only seven counties in the State have producing mines at the present time. Gila county leads in the valuation of its active mines, which are put at \$115,478,479. The other counties and the valuation put on the producing mines in each are as follows: Cochise, \$105,771,621; Greenlee, \$26,514,131; Mohave, \$6,372,846; Pima, \$23,348,756; Pinal, \$16,972,546; and Yavapai, \$88,624,356.

ARIZONA

Gleeson.—The Black Hawk Copper Co. has been organized by J. E. Pemberthy, and others, for the purpose of developing the Pemberthy group of claims in this district. Work will be commenced at once.

Kingman.—An increased scale of operation is planned at the C. O. D. mine owned by Morris P. Dudley and associates. The mill is handling 100 tons of ore per day and the company is shipping \$40,000 worth of concentrate per month. It is expected to increase the capacity to 150 tons. A double-compartment vertical shaft is being sunk 300 ft. north of the present incline shaft.

Following the resumption of milling operations at the Dean mine comes the announcement of the discovery of a

new shoot of high-grade gold-silver ore in a raise from the lower tunnel. The ore carries 80 oz. of silver and \$16 in gold per ton, with the indications favorable for the continuation of the shoot to surface, a distance of approximately 200 ft. The reconstructed mill is supplied with oil-flotation units and is handling 50 tons of ore per day. W. W. Elliot, mill superintendent, expects to have the plant working at 60 tons daily capacity within a short time.

The Silver Trails Mines Co., owner of the Diamond Joe mine, has purchased the milling plant formerly operated under lease. It is to be remodeled and enlarged to meet the requirements of the Diamond Joe mine. The remodeling plans include the construction of an aerial tram from the mine to the mill. A generous tonnage of oxidized and sulphide ore stands in the underground workings awaiting reduction. In the upper levels the ore is almost entirely silver-bearing, but in the sulphide area, carries a gold content of \$8 per ton in addition to average silver values of \$15 per ton.

Miami.—The Miami Copper Co. has declared a dividend of 50c. per share for the quarter ended June 30, 1921, payable to stockholders of record at the close of business on August 1. The distribution will be made on August 15.

Outman.—The United Eastern Mining Co. has declared a quarterly dividend of 15c. per share payable on July 28, to stockholders of record, at the close of business on July 8.

Patagonia.—Peter Hansen, who recently took an option and lease on the Rhea mine, three miles south-east of here, has moved the compressor from the Mansfield mine to his newly acquired property. Work is being done in the main shaft, which is 230 ft. deep. Hansen expects to ship lead-silver ore to the smelters within the next two months. John C. Holmes, who is working a placer claim between Bloxton and the Three R mine, says that his property is in excellent shape. He believes that the placer grounds would prove more valuable if worked on an extensive scale by dredging. Work is being rushed on concrete foundations at the Blue Nose mine of the Arizona-Patagonia Silver Mining Co. The new machinery has arrived at the mine.

CALIFORNIA

Angels Camp.—Fire of unknown origin destroyed the entire mine plant of the Sultana Mining Company on the night of July 5, the loss being estimated at between \$75,000 and \$100,000. The hoist, head-frame, compressor, and engine and boiler rooms, with all their equipment; the transformer house, blacksmith shop, change-house, oil-plant, and storeroom full of supplies, went up in smoke. The mill was 500 yards distant and escaped. The mine, formerly known as the Boyce, had an enviable record years ago. The property adjoins the Angels mine on the north; the shaft is 800 ft. deep.

Auburn.—The mining property owned by S. J. Caples has been taken over, under bond and lease, by James D. Stewart, and associates. Drifting into the old gravel channel has been started under the direction of F. A. Moss, superintendent. The property is located in the Last Chance mining district.

Bridgeport.—William Sanger is reported to have found a vein of rich silver ore at a place called Cow Camp in the Silver Creek range. The ore was found in a 50-ft. shaft. A bed of rich gravel has been uncovered in Dog Creek canyon by J. N. Beck, H. G. Beck, and associates. After a period of profitable operation, the placers were abandoned years ago when a layer of lava was encountered. Working on the theory that this cap was not thick the present operators dug through it and discovered a channel of rich gravel. A large number of claims were staked and C. B. McColm is said to be financing the work of hydraulicking the deposits.

Grass Valley.—A tentative agreement to arbitrate has

been entered into between the Mine Workers' Protective League, whose members are on a strike over wage conditions, and the Empire mine management, representatives of both sides announced on July 9. An order by the League to withdraw the pump-men from the Empire mine has been suspended for a week. In other mines the pumps are being operated by crews brought here from outside points.

Approximately 600 miners have been absent from their places in the local mines since July 1, when they refused to return to work at the new wage-scale announced by the operators during June. The operators published a statement early in June that when the old wage agreement expired on July 1 wages would be reduced \$1 per day.

The miners' organization submitted a proposal to the operators that the pay be cut only 50c. per day, but the

asks that its Sutro mine be reduced from \$59,160 to \$16,000, and its key-tone group of mines from \$32,000 to \$13,200. The company owns fifty outcrops in Kennett. They are assessed for \$15,000, and it asks that the valuation be cut to \$6,720, as most of them are vacant. The smelter, machinery, bag-house, railroad, tramline, and other appurtenances of the smelter are assessed for \$135,330. The company asks that the valuation be reduced to \$111,780.

Redding.—The Mountain Copper Co. has petitioned the supervisors of Shasta county to reduce the assessed valuation of its property from \$139,200 to \$50,000. It is alleged that existing economic conditions are such that the company's mines have only a "speculative" value. It is claimed that \$100,000 is a fair cash price and since the appraised value of property is approximately 50% of its true value,

No. 3 Mill of the St. Joseph Lead Co., at Elvino, Missouri

operators were insistent that the reduction be \$1, making \$4.62 per day for miners and \$4.25 for shovelers.

The Alta Combination Mines Co. is engaged in driving an air-shaft, from the 500-ft. point in its adit, to the surface. The company is searching for the Alta Hill gravel channel which it expects to tap by means of the extension of the tunnel.

Jackson.—The Crocker company is engaged in preliminary work for the exploitation of the Elephant Deep gravel mine. The old Volcano ditch that was used 40 years ago will be cleaned out to provide water for the project. This ditch is 28 miles long.

Kennett.—The United States Smelting, Refining & Mining Co. has petitioned the supervisors of Shasta county to reduce the assessment on its property from \$1,015,210 to \$230,371, the former figure being the valuation determined by the county assessor.

The company holds that because the price of copper has fallen from 18.5c. to 12c. in the last twelve months, its smelter and mining machinery in Shasta county are worth only what they will bring as junk. A year ago there were 119,322 tons of copper ore blocked-out in the Mammoth mine, but this could not be worked during the year except at great loss, and hence the mine and smelter have remained closed.

The Mammoth mine was assessed this year for \$448,720. The company asks that this figure be cut to \$39,391. It

\$50,000 should be a fair assessment. The company has commenced work on the construction of an aerial tram from the Hornet mine to connect with the Southern Pacific railway at a point three miles east.

COLORADO

Aspen.—Samples taken from the raise in the Hope tunnel, have shown a silver content of from 87 to 100 oz.; ore is piling up at the portal for later shipment.—John Cortellini of Leadville and associates are pushing development in the Park tunnel. An aerial tram for transportation of the ore is under construction.—The Midland tunnel is being extended to cut workings of the Midnight mine at depth.—A good grade of silver-lead ore is being saved for shipment by the Aspen-Silver-Lead Mines Co., of which J. J. Yeckel is manager.—Lessees on the Little Annie report cutting what is believed to be the apex of a rich shoot. The property is operated by the Richmond Hill company.

Cripple Creek.—Persistence of rich ore at great depth in the mines of the Cripple Creek district is evidenced by developments in progress at the Portland, Vindicator, and Cresson mines. At the Portland No. 2 shaft the orebody at the 24th level has been opened by drifts north and south of No. 2 shaft, 240 ft. north and 170 south. Ore in the north drift has been uniformly of smelting grade. Seventy feet of the south drift has been high-grade, the remainder mill-grade. On the 1500-ft. level the Lee shoot has recently been opened with rich ore appearing. The 12th-

level shoot was 70 ft. long; whereas the newer shoot is not yet proven.

At the Vindicator the new shoot opened up at 2000 ft. (Golden Cycle 19th level) is the extension of the Lillie shoot opened last year on the Vindicator 19. The new orebody, carrying "a very good grade of ore", according to George Stahl, manager, has been proven 300 ft. in length, and due to its sharp dip will afford around 200 ft. of stoping ground. The shoot extends within the area where the 20th-level station will be cut preparatory to raising the shaft through to connect.

The Cresson ore is being broken with machine-drills in stopes from 125 ft. to 150 ft. wide. This is in virgin territory, north, between the 1100- and 1200-ft. levels. This huge orebody is making 90% ore with but the coarsest sorting; the average assays are from \$12 to \$15 per ton. Many cars have returned one ounce gold per ton.

Georgetown.—The Mendota shaft has been unwatered by the Wasatch management and operations resumed underground.—E. E. Bush, with California backing, is operating the O'Connell property in West Argentine.—Operations are to be resumed by W. H. Barber of Denver on the Barber group at Empire.—At Apex the Saco de Oro company has opened a vein, new to the property, sampling close to four ounces gold per ton. The tunnel is projected to cut the Rochester vein that produced rich silver-lead ore from the Rochester shaft-workings before water brought a sudden termination to operations.

Kokomo.—Ore-bins at the Silver Queen mine of the Kokomo-Recon Mining Co. are full and awaiting cars for shipment of silver ore to the A. V. Smelter at Leadville.—The Kokomo Mining Co. continues development of the Pearl Consolidated group on Chalk mountain and is saving ore for shipment.

Ouray.—The capacity of the Mountain Top mill is to be increased 100%; the equipment is being delivered.—The Union Mining & Milling Co. has obtained transformers and other equipment saved from the Gold Crown mill, when the plant was destroyed by fire, and with new machinery is equipping the Union mill.—The working force at the White Cloud-Paymaster mines is to be increased as soon as a compressor is installed; machine-drills will then replace hand-steel. A mill is being constructed.

IDAHO

Coeur d'Alene.—Work on the tram at the Sidney mine is almost completed and shipments to the Bunker Hill smelter will soon be made from the stock of carbonate ore opened in the surface workings while tracing the vein along the hillside. The lower cross-cut tunnel is to be extended.—The new 50-ton concentrator at the property of the Sunshine Mining Co. on Big creek is rapidly nearing completion. The plant will be in operation within the next 60 days.—Reports from the Sterling Silver Mountain property, situated near the Yankee Boy group on Big Creek, state that the lower cross-cut adit has been advanced nearly 600 ft. and is now within 200 ft. of the main vein which has been opened by surface workings and by means of an upper adit from which good silver ore was obtained. The present cross-cut will reach the vein at a depth of 500 ft., while a drift into the hill will add an additional 500 ft. when vertically beneath the outcrop.

Development work at the Linton property, now known as the First National group, will include a cross-cut to the vein and drifting to a point beneath the No. 2 tunnel, where a body of ore was exposed. The property is well equipped with machinery for rapid and economical work. The Coeur d'Alene Syndicate Co., owning a group of claims near the west fork of Big Creek, has a crew of men at work driving a cross-cut adit.—On the west fork of Big creek the

Hartford group, the Silver Dale, and Big Hill are all being actively developed.

A shoot of rich lead-silver-zinc ore, more than 100 ft. long, with some of the clean ore reported to run 60 and 70 oz. in silver is reported in the old Sisters mine. Five carloads already have been shipped to the smelter, returning 33 oz. silver, 32% lead, and 16% zinc. Dan Murphy, superintendent of the Tamarack & Custer mine, is president of the Sisters Leasing Co. that is operating the mine.

Rush J. White has taken a bond on the Argentine property and has sublet his bond and lease to skilled miners who are working under his direction in an attempt to find ore. The ore is one that is particularly desired by smelters for its fluxing qualities. High-grade silver ore was mined 20 years ago.

The Callahan Zinc Lead Co. is actively developing its mine during the period of suspended production. The main three-compartment shaft has been sunk another 200 ft. from No. 10 to No. 11 level; drifting on this lower level has now been started. The work in progress at this point will open the orebodies at a point 1450 ft. below No. 4, or main-tunnel level.

Lakeview.—A geological survey of the area adjacent to the south half of Lake Pend Oreille, including the mining districts of Lakeview, Blacktail, and Granite creek, will be conducted this summer as one of seven projects undertaken by the State Bureau of Mines in co-operation with the U. S. Geological Survey. The area is one of considerable promise; small bodies of silver ore, accompanied by lead and zinc have already been found. The work will be in charge of the U. S. Geological Survey, under general supervision of F. B. Laney, head of the department of geology of the University of Idaho.

MICHIGAN

Houghton.—Beginning July 1, the Quincy Mining Co. lowered wages about 6%, making miners' wages \$3.15 per day and trammers' \$2.80. The new scale is about equal to that paid by Copper Range and the other operating mines of the district. There is no change in operating conditions at Quincy. The mine is working 4½ days each week with a minimum force. Production is understood to be about 1,000,000 lb. per month.

Sinking is under way in the Champion No. 1 shaft, in Trimountain No. 2 and No. 4, and in Baltic No. 2. Sinking in No. 3, Baltic, is about to start. Copper Range is well opened ahead and will be in a position to bring production up to a maximum when metal market conditions permit. No construction work of any extensive character is under way and no changes are being made in the milling plants.

Copper Range costs from this time on should show a considerable reduction. Wages are down to a pre-war level and the company is now operating with a new supply of coal which cost approximately half the price of that shipped in last summer. Coal is still 100% higher than in the pre-war normal years, but the saving effected will be large nevertheless. Nearly all of the old supply was used up early in June. Freight-rates have served to keep up the price on coal. Copper Range was fortunate, however, in being able to take advantage of the reduced lake freight-rate on coal.

A total of 5,858,000 lb. of copper was shipped out of the Lake Superior district by boat in the month of June. It is estimated that 1,000,000 lb. more, in the form of ingots, bars, and wire, went out by rail. Production for the month, including Copper Range, Mohawk, Wolverine, Quincy, and the Calumet & Hecla refinery output, was \$5,500,000 lb. Although metal sales fell off sharply the last ten days of June, the shipment figures indicate fairly large sales for the month as a whole. Of the water shipments, Calumet & Hecla sent 1,500,000 lb. to Germany and Copper Range, 700,000. The remainder was for domestic consumers. The

shipments by boat showed a considerable increase over those of May and those of June a year ago. In May the total was 5,310,000 lb. and in June of last year, 5,190,000.

According to advices from Detroit, many former residents of this district now in that city will return here when mining operations are resumed at properties now idle. A large number of these men are either out of work or dissatisfied with their present employment. One man writes: "If copper comes back next fall, or early in the spring, you'll see hundreds from this and other southern peninsula cities striking out for the Copper Country".

MINNESOTA

Duluth.—Shipments of ore from the head of the Lakes for this season to date total less than half what they were during the same period last year. In fact, shipments for

company has made money in every month this year, so it can be appreciated to just what extent costs have been reduced from the 15.25c average of 1920, and the high average of 16.58c. in 1919.

Fort Benton.—The suit of Oscar H. Goom, who alleged that his livestock had died as a result of inhaling gases and fumes from the Great Falls smelter of the Anaconda Copper Co., will be re-tried, as a result of the failure of the jury that heard the case to reach a verdict. The trial of the recent suit consumed four weeks during which 150 witnesses were examined.

Victor.—W. R. Price, of Helena, acting for Eastern capitalists, has obtained control of the Curlew mines, the sale price being reported as \$125,000. The mine was once a well known silver producer and is credited with dividends of

On the Talkeetna River in Alaska

June a year ago were greater than for the entire season thus far, the total this year being 6,107,479 tons, against 7,533,824 tons in the single month of June 1920.

MONTANA

Butte.—At the North Butte property, 70 men are employed. Drifting is being done on the lower levels of the mine and sundry raises are being completed. Work, however, is largely confined to keeping the mine in repair.—Development work is proceeding in the Butte and Plutas mine. It is reported that 2½ ft. of good silver ore has been uncovered in the Norwich vein on the 40-ft. level.

The East Butte smelter in June produced less copper than in the previous month. The May production was 1,726,000 lb., due to a clean-up of ore on hand, the large furnace operating that month instead of the small one. June output was approximately 1,000,000 lb., of which 50% is East Butte's own production, the remainder representing custom ore, largely Davis-Daly's. The East Butte

approximately \$1,000,000.—A new company is being formed to take over the Liverpool mine, another old silver producer; \$250,000 worth of silver ore was shipped from the mine during the most recent operations which ended with a shut-down about three months ago.

NEVADA

Divide.—The assets of the Victory Divide have been conveyed to the Reorganized Victory Divide Mining Co., which is assessable, and assessment No. 1, for 1c. per share, has been levied. A report by A. I. D'Arcy, president and general manager, says: "The mine is being developed by means of a two-compartment vertical shaft to a depth of 200 ft., and by means of an inclined winze on the vein to a depth of 500 ft. below the surface. Levels have been driven at the 200-, 250-, 310-, 360-, and 500-ft. points, totaling over 2000 ft. Just east of the shaft on the 200-ft. level is disclosed a large north and south fault, which displaces the vein, and it is our intention to drive a cross-cut north-east-

erly to pick up the faulted segment of the vein east of the fault and toward the Brougner Divide".

Goldfield.—The Silver Pick has a slope 10 ft. high and 10 ft. long above the drift in which ore was found in the foot-wall of the Red Top vein at a depth of 265 ft. The average grade of ore broken from the drift and slope is \$50 to \$70, according to Ben Gill, secretary for the company.

Hornsilver.—J. W. Dunfee, lessee of the Orleans, has shipped three carloads of ore to the MacNamara mill at Tonopah. The first carload assayed \$32, the second \$19; the third has not been sampled. This ore is coming from the 580-ft. level and Dunfee is prepared to continue the shipments indefinitely. The shoot has been opened for a length of 120 ft. and a raise is now being driven. The vein has not been cross-cut. Both the MacNamara and Belmont mills are prepared to handle the ore, which is ideal for cyanidation.

Klondyke.—Five 6-ton trucks, owned by Charles Wittenberg, a Tonopah contractor, are being used to haul ore from the Klondyke district to the mills at Tonopah. There is estimated to be 2000 tons of ore broken in the various mines, with 10,000 standing in sight. There is estimated to be at least 1000 tons broken in the Knox and, since the ore-shoot has been found on the bottom levels, there is a huge tonnage standing. Recent developments in the Original Klondyke have caused the owners, E. Marks and Harry MacNamara, to raise the price at which they will sell from \$40,000 to \$100,000. Five large samples of several hundred tons of ore being shipped from the Maupin and Logan sub-lease on the Original Klondyke gave \$48, \$69, \$33, \$27.70, and \$26. Strong and Darnell are shipping 100 tons of \$50 ore from their sub-lease. The ore from both of these sub-leases is being sent to the Belmont mill. The finding of ore on the bottom level of the Knox is regarded as being of importance because it indicates that the shoot extends to great depth on the lime-rhyolite contact.

Lone Mountain.—The vertical shaft being sunk by the Electric Gold Mines is 130 ft. deep and it will be continued to 200 before lateral work is started. The shaft has passed out of the vein into the foot-wall.

Lovelock.—Mining activity is being resumed at the old mining camp of Rileyville on what is known as the Japanese property, southeast of Lovelock. Jones & Clark who operate the property, report uncovering a shoot of high-grade ore assaying close to \$500 per ton, largely gold. The high-grade shoot is 12 ft. wide and 18 in. thick. The high cost of mining and transportation has delayed the operating of the property at full capacity but with the uncovering of the high-grade ore work will be resumed.

The Rochester Silver Corporation made its fortnightly shipment of bullion on July 7. The shipment is up to the regular average of \$28,000 to \$30,000. According to the management the underground conditions of the mine are still good with development work progressing at the rate of 750 ft. per month. The mill is operating at full capacity on the average tonnage held for the last two and a half years.

Mina.—The mill of the Simon Silver Lead Mines Co. is 90% complete. The company has negotiated a contract with the United States Smelting Co. to ship its lead concentrate to the smelter at Midvale. It is reported that the company has purchased the controlling interest in a smelting plant on the Californian coast in which it will treat its own zinc concentrates. The plan is to make zinc-oxide.

Montezuma.—The Harrell has started widening and re-timbering the 100-ft. shaft on the claims bought from Moon and Whitaker. It is planned to sink the shaft to 300 ft. and extend the drifts on the 50- and 100-ft. levels, which are in ore.

Silver Peak.—The Sanger-Taylor property near here has been sold to the Natural Soda Products Co., controlled by the Wattersons of Inyo county, California. The Sanger-Taylor property is a silver prospect with an 80-ft. shaft.

Tonopah.—The discovery of 1 ft. of free-milling gold ore at the bottom of a 95-ft. prospect shaft on the property of the Electric Gold Mines Co., is reported. The mine is in the Weepah district, 30 miles south-west of here. The prospect shaft is near the foot-wall side of the main vein, which is known to be over 70 ft. wide, and opens richer ore than has heretofore been developed. One cross-cut disclosed ore assaying from \$12 to \$20 per ton for the full width of 70 ft. A new engine is being added to the plant to give increased compressor capacity for running hammer-drills.

The West End Consolidated Co. shipped 33 bars of bullion, weighing 66,000 oz., the first week of July. Including the gold content the estimated value is \$72,000. The mine report says that raise No. 12, from the Ohio shaft, continues showing a full face of mill-ore.

It is reported that the second payment of \$15,000, on the purchase price of the Clifford mine in the Stone Cabin district, has been received here. This payment makes a total of \$22,500, leaving a balance of \$77,500. The recent discovery of gold ore, assaying \$150 per ton, has stimulated interest in this district where silver has hitherto been the most important metal.

UTAH

American Fork Canyon.—What appears to be the most important discovery made in this district during the past twenty years is the opening of 11 ft. of almost solid galena in the Echo claim of the Silver Wave group, according to C. B. Ferlin, manager for the American Leasing Co., which is operating the property under lease. The discovery was made in driving a tunnel from the Live Yankee mine. Twenty teams are employed by the company in transporting ore down the canyon and bringing supplies up to the properties. About 50,000 tons of mill-grade ore has been developed and a small concentrating plant is in operation.

C. W. Earl, superintendent of the Austin property, reports an important find in a 20-ft. raise from the Austin tunnel. An 18-in. vein of high-grade carbonate, with solid galena scattered through it, has been opened. In this same tunnel, about 75 ft. distant, gray-copper ore is being developed. An assay gave returns of 16 oz. silver and 16% copper.

Eureka.—In spite of decreased prices for lead and copper, the difficulty of marketing silicious ores and other vexations, the production of ore at the Tintic district for the first six months of 1921 totaled 3958 carloads, as compared with 3501 for the corresponding period of 1920. The increase was due principally to the large output of iron fluxing-ore at the Iron King mine and to the tonnage shipped by the Tintic Standard company to its new milling plant. The Tintic Standard was the largest shipper, its output being 1440 carloads, most of which went to the milling plant. The Chief Consolidated was second, with 894 carloads, and the Iron King third, with 339 carloads.

At the Eagle & Blue Hell and Victoria mines, both of which are being operated through the shaft of the former company, conditions continue to improve. There are now 125 men on the payroll, and during July this force will be increased to 150 men. Recently miners have been coming into this district from other camps. Four cars of ore per day are being shipped to the A. S. & R. Co., most of which is a silicious silver ore, the remainder being a high-grade lead product. At the Victoria mine the high-grade silver-lead ore found on the 1350-ft. level, then tapped on the 1450, has been reached with a drift on the 1500-ft. level.

Three shifts are now being employed by the Chief Consolidated Mining Co. in the sinking of the Water Lily shaft.

The shaft, having three compartments, has been equipped with modern hoisting machinery. Active development is planned.

An important discovery was made recently in the property of the Tintle Treasure Leasing & Mining Co., in the southern part of the district, according to J. S. Free, manager. The ore is in a fissure in the porphyry and has been developed for 33 ft. in length, with an average width of 2½ ft. Assay returns show 40 to 60 oz. silver and 20% lead. The orebody was opened at a point 185 ft. below the surface and 340 ft. from the portal of the adit.

Milford.—Operations have been resumed at the Bon Saldo Mining Co.'s property in the South Star district, according to George Miller, manager. The company has recently installed a gasoline hoist and a shaft has been sunk to a depth of 135 ft. The property adjoins the Moscow mine, once an important producer.

Moab.—A. W. Stevenson, president of the Pittsburgh Radium Co., operating claims in the Yellow Cat district, reports that a force of 18 men is at work. The company is building a reduction plant at Denver, which should be completed early in August. The principal product will be vanadium; it is said that the company has orders from Eastern steel-mills.

WASHINGTON

Springdale.—The Cleveand mine, 18 miles west of Springdale, resumed operations recently, after being closed down since last fall. The mine was once a producer; it is equipped with a concentrator and flotation plant. The chief metals are silver, lead, and zinc.—The Deer Trail mine in the same district is reported to be ready for operation, and the Queen and Seal has been shipping steadily for several weeks, loading a car of ore each week.

Spokane.—Members of the Columbia Section of the A. I. M. & M. E. will take an outing of three days, leaving Spokane August 21, for a visit into the east Kootenai mining district of British Columbia. The party will visit several camps, including the Sullivan mine where they will be entertained by engineers of the Consolidated Mining & Smelting Co. Arrangements have been made for transportation of about 50, including ladies.

BRITISH COLUMBIA

Grand Forks.—The Horn Silver mine has been acquired by Herbert Powell. Shipments have been made this year to the Trail smelter. It is said that Powell will endeavor to interest capital with a view to the installation of a small reduction plant.

Nelson.—The difficulty of identifying mineral ground held by Crown Grant and otherwise in some of the districts of British Columbia was discussed recently by the B. C. Prospectors' Association. Considerable areas, it was contended, should be re-surveyed, permanent location posts planted, and maps prepared on a scale of 1500 ft. to the inch showing all important rivers, creeks, and other topographic features mentioned in the original field notes. It is argued that forest fires, and the natural destructive agencies of nature have obliterated old land-marks.

Prince George.—The North Point Mining Co. is developing a promising silver-lead-gold property situated near Hudson Spur on the Fraser river and near the Grand Trunk Pacific Railway. Recent work is reported to have cut an 8-ft. vein showing good assays. The main adit now in 350 ft. is expected to strike the principal vein at about 600 feet.

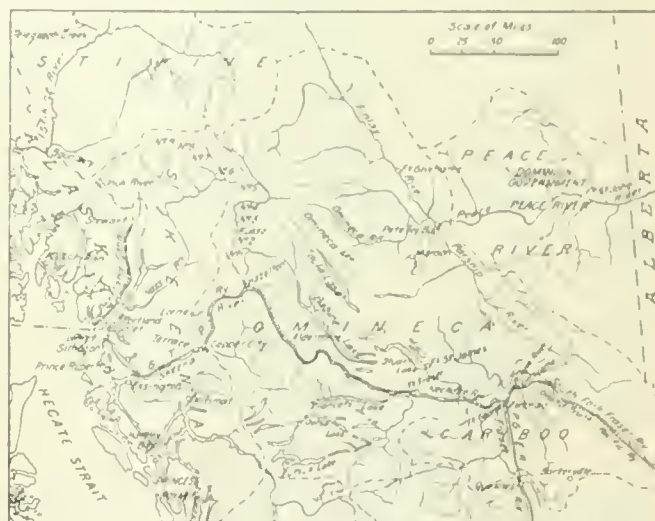

Revelstoke.—Frederick Keffer, of Spokane, is making an examination of the Lardeau district in the interest of Spokane capitalists, who, if the examination is favorable, contemplate operating a dredge in the district.

Trail.—The smelter receipts for the third week in June

totalled 6476 tons. The Florence mine, at Ainsworth, contributed 102 tons; Knob Hill, Republic, 50; Surprise, Republic, 87; and the Consolidated company's mines, 6237.

The abandonment of its Red Mountain branch by the Great Northern Railway Co. will leave the Josie and Velvet mines, at Rossland, without transportation facilities. More than a million dollars has been spent on the development and equipment of these mines. The owners of the Josie were about to erect a concentrating plant, and improvements had been planned for the Velvet, a strong company recently having been formed for the purpose. The Great Northern company claims that the line has been operated at a loss for some time, and no other course was open to the company.

Victoria.—The Provincial Department of Mines has issued the annual report for the year ended December 31, 1920. The final figures of the value of production come within \$50,000 of the estimate made by the Provincial Mineralogist at the commencement of the year, but some of the individual items vary vastly from the early estimate. Thus, for ex-

Part of British Columbia

ample, as your correspondent suggested at the time, the figures for the zinc production were altogether too high in the preliminary estimate, being some 29 million pounds in excess of the actual production. On the other hand, the figures for the lead production were some 18 million pounds too low, and were the means of doing much to counteract the error made in the zinc production. The following are the final figures, those of 1919 being given for comparison:

	1919		1920	
	Quantity	Value	Quantity	Value
Placer gold, oz.	14,325	\$280,500	11,080	\$221,600
Lode gold, oz.	152,426	3,150,645	120,048	2,181,392
Silver, oz.	3,403,199	3,592,673	3,377,849	3,235,080
Copper, lb.	42,459,339	7,030,890	44,887,676	7,832,899
Lead, lb.	29,475,968	1,526,855	39,331,218	2,816,115
Zinc, lb.	50,737,651	3,540,429	47,208,268	3,077,979
Coal, long tons.	2,267,541	11,337,705	2,595,125	12,975,625
Coke, long tons.	91,138	637,966	67,792	171,544
Miscellaneous products.		1,283,644		2,426,950
		\$33,296,313		\$35,544,084

MEXICO

Choix.—It is reported that the Lluvia de Oro Gold Mining Co. has nearly exhausted the present ore-reserves and will not undertake further development of the property at the present time.

YUKON

Dawson.—G. P. Mackenzie, Gold Commissioner for the Yukon, has been made a land commissioner for the Northwest Territories, in order that claims staked in the Fort Norman oilfield by Yukoners may be recorded at Dawson, thus avoiding a trip to Edmonton for the purpose.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

E. B. Rider is at Bisbee, Arizona.

A. G. MacGregor has returned from Peru.

M. A. Newman is at Los Angeles, California.

D. O. Lima is now at Minneapolis, Minnesota.

A. B. Shotts is now at Pittstown, Pennsylvania.

Gilbert Hart is residing at Haileyville, Oklahoma.

Henry F. Collins has returned to London from Spain.

Lewis L. Bradbury is on his way from Los Angeles to London.

Thomas H. Sheldon, formerly of Denver, is at San Martin, California.

Charles Butters is not expected home from Nicaragua until September.

Fred Searls, Jr., on his return hither from China, went to New York.

A. P. Mallon is with the Dean Mines company, at Kingman, Arizona.

J. N. Justice has returned to England from Demarara, British Guiana.

Paul R. Cook has returned from the Near East and is now at Itolla, Missouri.

John Hays Hammond was in San Francisco this week, on his way to the Orient.

E. R. Wolcott, of the Western Precipitation Co., Los Angeles, is in New York.

W. S. Stevens, of Chicago, expects to leave shortly for a two months trip to England.

Thomas P. Carr is now manager for the Cia. Minera Anglo-Hispana, at Leon, Spain.

L. S. Cates has returned to Salt Lake City, after a six weeks visit to Boston and New York.

C. F. Rand has been elected to honorary membership in the Iron & Steel Institute, of London.

A. R. Anderson is now with the Howrey Creek Mining Corporation, at Willisville, Ontario, Canada.

George C. Jones, general manager of the Minas del Tajo and other properties in Mexico, is at Palo Alto.

Norman C. Stines has been appointed receiver for the Alaska Mines Corporation and is now at Nome.

John B. Harper, of Jerome, Arizona, was in San Francisco recently on his way to Sonoma county, California.

Edward W. Packard, principal owner of the Gemini mine in the Tintic district, recently visited the property.

Algernon Del Mar has returned from Mexico to Los Angeles, where he expects to remain until the autumn.

C. W. Whitley, vice-president of the American Smelting & Refining Co., spent several days at the Tacoma plant of the company recently.

J. E. Scott, from India, is making a tour through the West, with a view to informing himself concerning American methods of leasing mineral land.

Percy E. Harbourn, the assistant secretary of the American Institute of Mining & Metallurgical Engineers, who has been seriously ill, is reported to be convalescent.

Charles Janin, in his capacity as consulting engineer to the U. S. Bureau of Mines, will make a study of cold-water thawing as used in alluvial mining in Alaska.

A. L. Field, formerly assistant metallurgist at the Pittsburgh station of the U. S. Bureau of Mines, is now with the

Union Carbide & Carbon Corporation, Long Island City, New York.

H. G. McClain and Webster P. Cary are now in partnership as McClain & Cary, mining and metallurgical engineers, at 708 Harrison avenue, Leadville, Colorado.

D. Vogt, the retiring president of the British America Nickel Corporation, intends to leave shortly for Norway, to take charge of the company's affairs in Europe.

T. Skewes Saunders, for several years the general manager for the Dos Estrellas Mining Co., at El Oro, Mexico, has opened an office at 525 Edificio La Mntua, Mexico, D. F.

The Hon. William Sloan, Minister of Mines for British Columbia, has been granted two months sick leave and has retired to his hunting-lodge, at Horn Lake, north of Nanaimo.

C. E. Davies has accepted the appointment of managing editor of 'Mechanical Engineering', and the 'Engineering Index', the two publications of the American Society of Mechanical Engineers.

Frank G. Janney, general superintendent of mills for the Utah Copper Co., at Garfield, Utah, has resigned, effective July 1. He is now associated with the Stimpson Equipment Co., of Salt Lake City.

Paul Hillsdale, a well-known mining engineer of Utah and Colorado, was married on June 21, at Eureka, Utah, to Miss Maude Fitch, daughter of Walter Fitch, president of the Chief Consolidated Mining Company.

Robert W. Butler has been appointed manager for the Mine & Smelter Supply Co. at Salt Lake City, succeeding W. R. Thurston, who has accepted a position with the McIntosh-Seymour Corporation, of New York.

Ralph S. Baverstock, of Baverstock & Payne, Los Angeles, having returned from an examination trip to the Mt. Gleason mining district, has left for Mojave. H. L. Payne, of the same firm, has gone to Yuma and to the Dome district on mining business.

Charles Salter, works manager of the Straits Trading Co.'s tin smelter at Singapore, is making a tour of metallurgical and mining districts in this country. He spent several days in Utah recently. He will sail from New York on July 23 for Liverpool, on his way home.

C. Yale Pfoutz, of Salt Lake City, who has been metallurgical engineer with the Utah Copper Co. for a number of years, has accepted the position of Assistant Professor of Metallurgy at the Colorado School of Mines. He will take up his new duties on September 1.

W. A. Clark, president of the United Verde Copper Co. and the Ophir Hill Consolidated Mining Co., spent several days in Utah recently, visiting the property of the latter company. He will sail from San Francisco on August 2 for a vacation in Honolulu.

Obituary

William J. Richards was killed recently at the Monongahela mine at Crystal Falls, Michigan, as a result of an accident due to the overwinding of a cable.

John Gately May died recently at Denver, Colorado. He was born on April 24, 1880. After completing his junior year in the Fremont High School he took a mining engineering course at the Colorado School of Mines, at Golden, Colorado, graduating in 1901. He then spent three years in San Javier, Sonora, and Durango, Mexico, in professional work. After returning to the United States, he made his headquarters in Denver, where he continued his studies and research work, taking up civil and electrical engineering. He traveled extensively, visiting and studying various mining projects in Colorado, Wyoming, Nevada, California, and New Mexico. He was connected with a number of domestic and foreign mining corporations.

THE METAL MARKET

EASTERN METAL MARKET

(By wire from New York)

July 11.—Copper is inactive and soft. Lead is quiet but firm. Zinc is dull and steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46 65 pence per ounce (925 fine), calculated at the normal rate of exchange.

WE CAN MAKE PROSPERITY

We have one hundred millions of people the most resourceful and enterprising on earth. Not all of them are producers, but every living one of them is a consumer says the 'Manufacturers Record'. They are accustomed to a high standard of living. They do not scruple themselves in food, or clothes, or pleasure. They have no faith in the philosophy that man is put on earth to do without. They believe that it is high motive to have large desires and achieve in such a way as to be able to satisfy them.

There is nothing more foreign to the American disposition than a buyer's strike. Americans fail to buy primarily not because they are on strike, but because they are without the means to buy. There was sharp run and the shadow of impending disaster in the repeated warnings of Government officials last year that people cease from purchasing. It meant the beginning of a cycle of stagnation.

The economists said that the solution of the world's great problem was production and more production. All production has been cut to the minimum. There is hardly a basic commodity in the wide world whose production is not at the lowest. Be it steel or lumber or the things that grow out of the earth, there is underproduction in all alike. And this at a time when the world has four years of destruction to make good! This at a time when every factory in the world might run day and night for years before making up the deficiencies! There is tomorrow's sun. There are economic laws which are as sure and fixed in their working as the rising tide. The underproduction of today foretells the insatiable demand of tomorrow. Not only will the 100 millions of people in this country begin before long to meet their needs, but so will the millions abroad. And the first signs of the rising tide will bring so soon a sense of confidence that rising prices, like a healing flood, will stir to life every channel of trade.

None knows better that we do the tragic mistakes which have been made. We exposed them before they were made, but our voice of warning was as that of one crying in the wilderness. Those mistakes are now, at last, everywhere being recognized. The Government is reversing its credit policy, slowly but surely. Counterblasts to the devastating publicity put out from Washington last year are being issued. A new psychology is being built up—the psychology of faith and enterprise. No longer is Washington advising people not to buy. It is urging them to buy.

Men still go about their business, still eat still sleep, still walk, still play, still love, still fight, still leisure, still have ambition, still labor, still spend. There is nothing that can hold them back. Peoples that conquered the Hindenburg line and smiled through years of hell will not succumb and lie them down to die because depression in trade has swept like poison gas over the land. They who won the war can win the peace; they can and they will MAKE prosperity.

MONEY AND EXCHANGE

Foreign quotations on July 12 are as follows:

Sterling, dollars: Cable	3.61 1/2
Demand	3.65 1/2
Francs, cents: Cable	7.90
Demand	7.88
Lire, cents: Demand	4.59
Marks, cents	1.36

Eastern Metal Market

New York, July 6.

The tariff, with its new duties, is the principal topic discussed in market circles in the absence of any activity. The new tariff carries proposed import duties on tin, lead, and zinc. There has been little change in prices, which are firm to higher.

Buying of copper is still very light; price-changes have been insignificant.

Selling of tin has been confined to one day with prices firm and steady.

The lead market is very quiet with prices decidedly steady.

Prices in the zinc market are slightly higher but buying is still confined to urgent needs which are small.

IRON AND STEEL

The reduction in prices of various steel products formerly made on July 5 by the Bethlehem Steel Co. have been met by such of the other producers as were not already selling at the new Bethlehem levels. The fact is, that, as to some products, the announcement merely recorded what the market already had done, says 'The Iron Age'.

For the six months ending June 30 the country's pig-iron output, exclusive of charcoal iron, was 9,428,000 tons, against 18,139,000 tons in the first half of 1920.

Opposition in the steel trade to the metal schedule of the new tariff bill centres on the manganese ore and ferro-manganese duties, which steel manufacturers consider far too high. There is also the anomaly that 20 units of manganese in spiegeleisen pay \$1.25 duty, whereas 80 units in ferro-manganese pay \$39.42, or at nearly an eight-fold rate. The general provision for American valuations would be of little help in keeping out European steel, since nearly all steel duties are specific and hence do not involve valuations.

COPPER

It is understood that the one or two small interests which were selling copper at the lowest prices, recently have either parted with all the metal they have or have withdrawn from the market. This has stiffened the market to some extent but prices for most of the business being done remain the same on the average as a week ago, namely, 12.87½c., delivered, or 12.62½c., New York, for July delivery. Some sales have probably been made under this level but it represents the general market. In any event, sales have not been heavy. Most, if not all, of the so-called large producers are still out of the market and quoting nothing less than 13 to 13.25c., delivered, for July. The Lake copper market is practically on the same level as the electrolytic.

TIN

The feature of the week has been the duty on pig-tin, proposed in the new tariff bill submitted to Congress last week. It carries a duty of 2c. per pound on pig-tin with tin ore admitted free. This contrasts with the request for 10c. per pound on pig-tin and 6c. per pound on tin contained in ores, which was favored by important interests. The moderate duty, while not as acceptable as free tin which is the rule now, is a matter of satisfaction to importers in that it is so much less than seemed imminent at one time. The week has been a quiet one, almost stagnant except for one day; on July 1, about 300 to 400 tons was sold consisting of prompt shipment from England and of future shipment from the East at 29.25 to 29.37½c. This was bought by dealers largely. Prices have been firm to higher here and in London. Yesterday British prices were £4 to £5 per ton higher than a week ago with spot standard quoted at £172 5s., future standard at £174 5s., and spot Straits at £172 5s. per ton. The spot Straits market at New York has been between 29 and 30c. during the week, with the quotation yesterday at 29.87½c. The quantity of tin delivered into

consumption during June was 1590 tons with the amount in stocks and landing at 2546 tons on June 30. Imports to July 1, this year, were 8918 tons against 27,743 tons to July 1, 1920, or only about one-third.

LEAD

The feature of this market is the fact that in this locality at least, no metal can be bought from any of the independent producers. The leading interest therefore has the market to itself at 4.40c., New York, which is also the quotation at St. Louis. Independents there, however, are selling around 4.25 to 4.35c. for delivery in Chicago and the West. Independents, if they quote at New York, are offering nothing less than 4.62½c. The new tariff proposes a duty of 2½c. per pound on pig-lead as against the ad valorem duty, now, of 2.25%. This is a decided advance for with lead selling at 4c., London, as today, this would mean a cost of 6½c., duty-paid, seaboard, as against 5c. now, freight not being considered, or being the same in both cases.

ZINC

Prices of prime Western for early delivery in wholesale lots are slightly higher at 4.35c., St. Louis, or 4.85c., New York, or 10 points above those ruling a week ago. This is due partly, it is said, to the proposed duty of about 2c. per pound, effective for the first year after it goes into effect, but probably the major factor in stiffening the market is the fact that no producer will sell under this level and that those who were willing have disappeared. Demand is still confined to small lots for immediate needs and it develops now and then that some consumers have large stocks and others have almost nothing. Some who had large stocks sold them at a loss some time ago and are buying only as their needs develop, usually at lower levels.

ANTIMONY

Wholesale lots for early delivery are quoted at 4.75c., New York, duty paid, with the market quiet. Jobbing lots are about ½c. per pound higher.

ALUMINUM

The leading producer continues to quote wholesale lots for early delivery unchanged at 28c. f.o.b. producer's plant, while the same grade from foreign sources is obtainable at 22 to 23.50c., New York.

ORES

Tungsten: No change is recorded; the market is quiet. Quotations are nominal at \$3 to \$3.25 per unit for Chinese ores with Bolivian and other ores at \$3.75 to \$4 per unit.

Ferro-tungsten is unchanged at 48 to 50c. per pound of contained tungsten in lump form, guaranteed as to quality.

Molybdenum: The market is without feature with quotations nominal at 50c. per pound of MoS₃ in regular concentrate, usually 85%.

Manganese: There is no demand with quotations nominal at 22.50c. per unit for high-grade foreign ore. A duty of 1c. per unit is contained in the proposed new tariff bill.

Manganese-Iron Alloys: There is no activity in either ferro-manganese or spiegeleisen and prices are nominal, those for ferro-manganese being \$75, seaboard, for the British alloy and \$80, delivered, for the American. Prices for spiegeleisen are \$30, furnace. A carload of ferro-manganese is reported sold at about \$72.50, delivered, and there are inquiries for two 100-ton lots of spiegeleisen. The production of ferro-manganese in June, according to blast-furnace reports of 'The Iron Age', was only 4536 tons, or the lowest for any month on record. No spiegeleisen was made in June. The tariff on manganese ore and ferro-manganese is a topic of much interest, with various views depending on the person or company interested.

T. A. RICKARD. . . . Editor

PRESIDENT HARDING'S message on the Bonus Bill reminds us of the story of the Chinese cook and the tramp. The latter opened the kitchen-door and said, "I want something to eat". "You eattee flish?" asked the suave Chinaman. "Yes." "All lite, you come Fliday." Joking apart, the President has shown courage and good sense in opposing a gratuity of \$500 to every service man, while at the same time emphasizing the need for concentrating any national benevolence upon those who are disabled or dependent. We hope that his wise action in this matter will serve to encourage efforts toward Federal economy in other directions.

ACCORDING to the 'Pioche Record', the 'Mining and Scientific Press' has "endorsed the new sensational bonanza silver camp" of Silverhorn, and to the Editor personally, as a "famous geologist and writer", is credited responsibility for this unqualified endorsement. All this appears in a telegram dated from New York as if to give it additional credence. The basis for these friendly exaggerations is an item that appeared in our news columns, for the accuracy of which the Editor is only indirectly responsible. We have correspondents in the various mining districts and they send us the sifted gossip of the camp; that, of course, is news, but it is a long way from being an expression of editorial opinion. We note that "a big interest" in the Silver Peer prospect has been sold to 'Tex' Rickard, so next the Editor will be credited with speculating on his own account, for the fight promoter has been identified more than once with him. Mr. George Lewis Rickard is a useful man in his day and generation, but we are not warranted in claiming any kinship, physical or mental, with him. As for Silverhorn, it is a promising district and we wish it good luck. That is all.

THE Commissioner of the U. S. Patent Office describes that institution as the largest 10-cent store in the world: for it sells weekly a vast number of specifications at that modest figure from its assorted stock of 75,000,000 copies. However, something more than financial success is needed, for the department is one of national importance. This being the case, it is all the more regrettable that conditions are such that a constant stream of its officials are 'seeking pastures new'. It is reported that over 100 examiners have resigned within twelve months, as well as nearly 150 of those in clerical posts.

All appear to be poorly paid, 30 clerks receiving no more than \$60 per month. The United Engineering Societies has issued a statement that draws attention to these wholesale resignations, and also to the fact that the Office is reaching a point of disorganization that threatens a crisis. Immediate legislation is necessary. The situation is described in this issue by Mr. K. P. McElroy, whose article we have re-printed from the columns of our contemporary, the 'Journal of Industrial and Engineering Chemistry'. As Mr. McElroy contends, a man of education and standing needs something more than salary to keep him in the job: he requires a certain amount of pride of place and dignity of position. If paid merely what he is worth and what he can command elsewhere, and if there are no other inducements, inertia is all that will hold him. The salaries paid in the Patent Office are too low, and there are no other inducements; hence the present chaos.

COLONEL GEORGE HARVEY must feel foolish when he meets veterans of the recent war or of other wars, of which there have been plenty during the last twenty years, for his military title is based upon service as a colonel and aide-de-camp on the staff of a Governor; indeed he must have been fond of the masquerade for, according to 'Who's Who', he has accepted that theatrical appointment four times, twice on the staff of a Governor of New Jersey and twice on the staff of a Governor of South Carolina. He is a clever man, why did he do it? Did it ensure him a railroad pass or sundry perquisites? Here we may note that both the 'New Republic' and the 'Weekly Review' write about 'Mr.' Smuts while they refer to 'Colonel' Harvey. It may not be surprising that a paper so ill-mannered and showing so little sense of humor as the 'New Republic' should make the blunder, but that self-appointed antidote to radicalism, the 'Weekly', ought to know better, for the South African statesman has been in command of armies in two great wars while Mr. Harvey was participating in the political vaudeville of two provincial Governors. Colonel House likewise obtained his military title by serving on the decorative staff of a Governor of Texas; he must have felt like a chump when asked when and where he had seen service as a soldier, particularly when he found himself in the presence of generals who were commanding the biggest armies that the world had ever seen in battle array. Surely it is time for an American

of distinction, notably an Ambassador, to drop these provincial trappings. 'Mr.' is a prefix good enough for the representative of our democratic Republic.

SUFFICIENT ore has been treated at the new plant of the Shasta Zinc & Copper Company at Winthrop, California, to prove the technical success and economic practicability of the process developed by the River Smelting & Refining Company at Florence, Colorado, for the smelting of the complex sulphide ore from the Bully Hill mine. The treatment of this ore has been for years the subject of investigation by numerous metallurgists, especially with respect to that class of ore in which the zinc content is high and the copper low; this naturally had been allowed to remain in the mine as long as profitable operation on ore richer in copper was possible. That now being smelted contains about 25% zinc and 2% copper, together with some gold and silver. It is crushed and roasted in McDougall furnaces preliminary to smelting in a reverberatory. The design and operation of the furnace differ in no essential particular from the ordinary copper reverberatory except that a combustion-chamber is provided for the oxidation of volatilized zinc as effected in the standard Wetherill furnace for the treatment of oxidized zinc ores. The copper carries the gold and silver into the matte. Exact analyses are not available, but we are informed on good authority that the matte is low in zinc and the slag reasonably low in both zinc and copper. The grade of the zinc oxide, collected in a bag-house of the usual type, is excellent; it is comparatively free of lead, and is contaminated with neither soot nor sulphates to an objectionable extent. The absence of lead makes it suitable for use in the automobile-tire industry, whereas freedom from discoloring matter fits it to serve in the manufacture of paint. Aside from the practical demonstration of the suitability of a reverberatory furnace for making zinc oxide, the success of the new plant is of interest because it may lead to the treatment of large quantities of complex ore elsewhere in California. Credit is due to Messrs. R. C. Beals, general superintendent, J. C. Kiunear, consulting engineer, and J. H. Rose, smelter superintendent.

IN this issue we publish a synopsis of the annual report of the Chile Copper Company, with interesting data concerning the year's operations at Chuquibambata, as well as the concluding article of a series on the enterprise, by our Mr. A. W. Allen, who visited the property last year. The two accounts, one official, and the other from a detached source, have much in agreement; Mr. Daniel Guggenheim makes no idle boast when he says, in the report, that the operations of the company "have now passed the development stage; the metallurgical predictions of your engineers have been met; your company has an extremely efficient staff of loyal and expert employees, and has arrived at a permanent stage of consistent and highly satisfactory operating results". The figures speak for themselves, and the policy of the company, in placing all technical information in the hands of those

who are interested, is to be commended. Speaking of the financial future of this great enterprise, Mr. Guggenheim is optimistic. Holders of copper securities will soon be rewarded for their patience, he says. The lowest estimate, based on conditions as they exist at the present time, but not taking into consideration the large increase in the demand for copper that should come from Germany and the rest of the world, indicates that the consumption of copper is about 675,000 tons per annum, and the mine production about 375,000 tons per annum. At this ratio it is obvious that it will not take long to absorb the entire copper surplus. It is estimated that production is now about 30% of normal consumption, as based on pre-war statistics, plus the usual annual increase as in the past. The German plants that manufacture copper products are now re-established at full capacity. Raw material in quantity will be needed in Germany, so that the indemnity obligations can be met by the exportation of finished articles. In addition, the high price of coal, the relative cheapness of water-power, and the increased demands for such facilities as telephones and other electrical apparatus, will ensure a strong demand for the copper on which the electrical industry depends. We share Mr. Guggenheim's optimism, and believe that a revival in the industry is not far off.

'DISCUSSION' this week starts with a valuable analysis of the conditions governing the possible, or probable, establishment of an iron and steel industry on the Pacific Coast. The writer, Mr. Nicol Thompson, has made a special investigation of the subject and is thoroughly competent to discuss the matter authoritatively. Mr. R. H. Stretch, now residing at Seattle, is known to our readers as the author of that useful book on 'Prospecting, Locating, and Valuing Mines'. Recently when at Virginia City we saw his name on some old mine-maps, reminding us that he is a veteran indeed. We wish he could find time to record some of his experiences on the Comstock during the spacious times of the boom in the 'seventies. The new mining law as yet has not been received with favor by the prospectors who have written to us on the subject. Both Mr. W. W. Rush, of Kasaan, and Mr. L. I. Munson, of Republic, dislike sundry of its provisions. We shall be glad to hear from those who like the proposed revision; there must be many who favor it. Mr. Charles A. Bramble writes pleasantly, from Winnipeg, on the educating of an engineer, and gives the experience of his own life. Such testimony is valuable. We agree as to the basic value of mathematics as a training for the mental faculties. Mr. Bramble's Latin may have been scant, but it was enough evidently to help him in the use of our language, to which Latin has contributed so much, particularly for scientific usage. Our friend 'P. B.', as he is known to his acquaintances, writes from London in continuation of his little difference with our Mr. Allen. We agree that reviews should give the reader a fair and complete idea of the contents and character of a book, because, after all is said, the primary purpose of a review is to tell the reader whether

it will be worth his while to purchase it or obtain a copy at the nearest library. The last letter of 'Discussion' this week is particularly interesting because it is a legitimate and proper protest from a minority stockholder against laxity, if not impropriety, in the management of company affairs. With such protests, when honestly made, we have the utmost sympathy. Mr. Richardson is Professor of Latin in the University of California; he is one of our foremost educators, and a man widely known for his sagacity in such public affairs as come within his wide scope. In our issue of May 28 we published a letter from Mr. C. G. Fowler, in which a complaint similar to that of Professor Richardson was made against the Consolidated Gold Fields management of the American Trona Corporation. Mr. Fowler bought a large block of shares as a speculator. The Professor's interest is that of an investor, for he speaks in behalf of a holding of stock purchased by the late Warring Wilkinson, the father of Mrs. Richardson. We give these details so that the Gold Fields offices in London and New York will appreciate the good faith of his actions in this matter. Letters sent to them have not been answered. This is not only impolite, but stupid. Shareholders have the right to have reasonable questions answered, and, in any event, to have their letters acknowledged. This high and mighty way of treating minority shareholders is out of date, and it will do no good to the Consolidated Gold Fields if it expects to do business pleasantly in the United States. The Trona Corporation has been the victim of many blunders; of that there is no doubt; the least that those in control should do is to show some sense of decency in the treatment of bona-fide complaints.

The Tariff

In our issue of July 9 we summarized those provisions of the Fordney Tariff Bill that affect the mining industry. Naturally, any legislation that is beneficial to our clientele, the mining public, is agreeable to us, if it is not detrimental to the welfare of our country as a whole. That, of course, is not the sentiment that rules in Congress; in that gathering of Solons, as the daily press, unaware of the satire implied, calls our legislators, the framing of a tariff is chiefly a game of 'log-rolling', which is an arrangement between law-makers whereby groups trade their votes, so that, for example, the grower of almonds in California will support a duty on the pins made in Vermont, provided the Vermonter will vote for a duty on almonds, the net result being a duty on both pins and almonds, without regard to the welfare of the majority of our citizens not participating in the production of either pins or almonds. Forty years ago General Winfield Scott Hancock described the tariff as "a local issue", thereby raising a laugh that proved disastrous to his Presidential candidacy. Unfortunately, whatever the view of most people on the broad question of free trade versus protection, it is a fact that when a tariff bill is being framed its details are decided in accord with the desires and insistence of local industries and of special

interests. This makes the whole question unsatisfactory and irritating, because it is so difficult to discuss it without prejudice. Even that excellent lady, Mrs. Robertson, the member from Oklahoma, stated that she would vote against a duty on hides because she cared more for the children, who use leather for shoes, than for the packers. There are more poor children than rich packers, seems to be her generous reasoning. Our own view is that we should protect young industries that would be killed by unrestricted foreign competition, in order that such industries, if essential to the country, may become firmly established and thereby contribute to making our country self-contained. During the War we found that for many essentials, such as dyes, potash, and antimony, we were dependent entirely upon importation. We proceeded to develop these industries in a hurry, and a good start had been made when the Armistice restored the *status quo ante*, thereby blighting the expectations of those who, in response to the national need, had started to make us independent of a foreign supply of these particular products. Most of us warmed to the idea of a self-contained country, that is, one which, if isolated in time of war, might be able to dispense with the importation of anything it needed for daily life and domestic industry—not luxuries or other non-essentials. That argument is being used in behalf of many of the metals and minerals mentioned in Mr. Fordney's bill. For instance, our production of tin is so small as to be negligible, yet the use of tin, for plating sheet-iron, is a matter of no small importance; so a duty on tin is advisable if it help to stimulate prospecting for tin ore, with a view to establishing a tin-mining industry that may make us independent of the Straits Settlements, the Malay States, and Bolivia. Antimony is another metal that we produce hardly at all; if a duty should serve to incite interest in the development of our own deposits of antimony, and if we have any large enough to supply the domestic demand, then in this case also an import duty might be advisable, not to enrich a small group in the community but for the benefit of the community as a whole. The war argument, however, breaks down when applied to the exploitation of known resources, for if the price of a metal or mineral be raised artificially by a tariff, it is obvious that the increase of price will hasten the exhaustion of the reserves during peace-time and, possibly, may cause the domestic supply to be depleted by the time we find ourselves again at war. It were better, from the point of view of the nation, to exhaust the resources of China or Brazil, in respect of a particular mineral, and to buy it cheaply from those countries during peace, than to pay high prices for the mineral and exhaust our own reserves, as against the time when those reserves may supply an urgent need. Such an argument is adverse to many of the duties suggested, but it supports the levy of a tariff on dyes and potash, for example, both being products of vast industrial importance that we ought to produce ourselves on a large scale. The granting of a duty on aniline dyes or on potash salts may benefit a small group, but that is not objectionable, pro-

vided it conduces to the welfare of the nation.

A few days ago we heard Mr. Adolph C. Miller, a director of the Federal Reserve Bank, speak in public on financial affairs in their broadest aspect. He had many wise things to say, particularly in emphasizing the fact that the present financial unpleasantness is due to the effort to readjust relations between the producing and the consuming capacities of different parts of the world. He adverted to the marked decrease in exports, which declined 55.9% in May as against the same month of last year. He recognized the truism that when your customer has to pay in cash, a rapid shrinkage of business with him is in sight. If, on the other hand, you buy from him he is enabled to establish a credit. The recent increase of half a billion dollars in the amount of gold held by the banks of the Federal Reserve system has caused some short-sighted publicists to chortle, whereas any sane economist sees that it is by no means a factor favorable to our foreign commerce or to our national welfare. When a fellow begins to pay for things with family plate or his wife's wedding ring, it augurs badly for further trade with him. That is Europe's status toward us. Apparently the gentlemen in Congress, and some outside, expect to export without importing; they expect to open up foreign markets while themselves sitting behind a Chinese Wall of tariffs; they count upon the prosperity of the United States while the rest of the world falls into the abyss. Yet Mr. Miller never mentioned the word 'tariff'. He feared to do so. Likewise, Mr. Hoover, one of whose recent public addresses we take pleasure in printing on pages 131 to 134 of this issue, makes a plea for a larger vision and an ampler perspective in world affairs, yet he also shies from any direct reference to the tariff, which is the negation of all the sane and generous ideas of men of his type. Of course, it is obvious, as many times before, that the arrangement of such a matter as the tariff should be based upon the recommendations of a non-partisan body of experts, such as exists in the form of the Tariff Commission; it should not be left to the mercy of a group of log-rolling legislators, in disregard of the recommendations of the Commission. The tariff is not economies; it is merely cheap politics.

Electricity and Copper

During the decade that ended with 1914, the electrical industry probably absorbed a half or slightly more of the world's supply of newly mined copper. Statistics are not in close agreement, but the available data make it certain that under normal conditions the use of copper for making electric conductors was by far the most important item in the gross consumption of the metal. The demand for brass during the War, coupled with the curtailment of sundry peace-time industrial activities, temporarily deflected the normal flow of metal from its accustomed channels. Following that came the period of obstruction and stagnation, with the consequent shutting-down of the copper mines. Unmistakable signs, however, point to the early disintegration of the restricting bar-

riers; then it may be expected that the normal channels again will carry their share of metal into useful industries. Of these the creation, distribution, and utilization of electric energy should be the greatest; and as compared with former times the future requirements of the electrical industry should assume gigantic proportions. A few concrete examples may be cited to indicate quantitatively the importance of copper in the application of electricity. The San Joaquin Light & Power Company of California has just added to its 'connected load' some 46,000 horse-power; 2,000,000 pounds of new copper wire was required merely to connect the plants, factories, and homes of the new consumers to the distributing system that already was in existence. According to a survey made by the 'Journal of Electricity and Western Industry', there will be constructed during the next decade in eleven Western States new plants to generate 2,800,000 horse-power of electric energy; assuming the use of wire in the same proportion as in the work of the San Joaquin company, the final connections to be made would require about 280 million pounds of copper. A second important use of wire is in the manufacture of electrical equipment, including generators, motors, and switchboard appliances. High-tension transmission lines and the local distributing mains entail a still greater use of copper. The Pacific Gas & Electric Company is about to commence the construction of a double-circuit transmission line, 172 miles long, to connect the new hydro-electric plants of the Pit River project, in the Sierra, to a new sub-station at Vacaville. The current will travel over six stranded rope-lay cables, each with a capacity of 500,000 circular mills, which makes them approximately one inch in diameter; the line is designed to transmit ultimately 320,000 kilowatts at 220,000 volts. The power company has recently purchased from the Anaconda Mining Company 10,000,000 pounds of copper wire, three-fourths of which will go into this single high-tension line. Three features of plans for up-to-date electric-power enterprises enhance the importance of long transmission lines as a factor in consuming copper. These are (1) the general development of hydro-electric power projects. The source of the water-power, and consequently the site of the generating plant, is usually far distant from the region where the electric current is consumed. (2) The tendency to erect large coal-fired steam-electric plants at the mine, to take the place of great numbers of small generating units situated at the immediate point of consumption. (3) The growing acceptance on the part of capitalists of the fact, always appreciated by engineers, that efficient utilization of power resources depends upon the replacement of steam in plant and factory by electricity, and the inter-connection of generating units to form immense distributing systems from which a reasonably high load-factor can be obtained. The plan to construct a system of this kind to supply approximately 15,000,000 horse-power to consumers in eleven North Atlantic States is probably the most elaborate undertaking ever conceived, but there is reason to believe that it will be accomplished in part at least. A preliminary

report on the engineering aspects of this so-called Super-Power Survey has already been made, and the legislative, legal, and financial phases of the plan are being studied thoroughly.

Electrification of railways and the supplying of 7,000,000 horse-power for operating trains is contemplated in this huge undertaking, and similar electrification of railroads in all parts of the country is being considered. That electricity is the only logical form of power for this purpose is conceded by everyone; even though hydro-electric power be not available, there is no possible economic justification for transporting coal all over the country and burning it in thousands of locomotives instead of generating electricity at the coal mines and distributing it by copper wire. Virtually the first long stretch of electrified railroad was the division of the Chicago, Milwaukee & St. Paul road between Avery, in Idaho, and Harlowtown, in Montana, a distance of 480 miles across the Rocky Mountains. The locomotives draw 3000 volts of direct current from two '0000' bare copper wires, each of which weighs 3280 pounds per mile; in addition, the rails are bonded at every joint with three-foot pieces of the same wire; and one '000' high-tension wire and one feed-wire of 500,000 circular-mills capacity extend over a large part of the line. The total weight of copper used is about 20,000 pounds per mile for a single-track line; manifestly, the electrification of the roads, which cannot long be delayed, will afford an important outlet for the product of our copper mines during the years to come.

The United States will not be alone in equipping its railroads with electric power. Plans were matured in Great Britain in 1914 for the division of the country into power districts that were to be supplied from large central stations, where electric energy by efficient management was to be produced in steam-plants for less than a half-penny per kilowatt-hour. This comparatively low cost had already been obtained in some plants. The War postponed the necessary construction, and since the Armistice the problem of financing has been the most serious obstacle. However, the strike of coal miners has emphasized the necessity for obtaining the maximum efficiency from available fuel, and the project of electrification will be undertaken immediately. The 'Boston Financial News' recently published a summary of reported plans for electrification abroad, which we presume to be authentic. The Midi system in France has announced plans for the harnessing of water-power to supply electricity for the operation of 1700 miles of railroad, 1000 miles of which will be electrified within five years. It is said that the River Rhone alone will be developed to supply several million horse-power of hydro-electric energy. A commission has been sent by Italy to investigate the methods used in the United States in anticipation of utilizing domestic sources of water-power for operating several thousand miles of railroad. Switzerland has sold \$25,000,000 of bonds in this country, the proceeds of which will be devoted to electrification, according to reports. Projects are under way in Belgium, Spain,

Sweden, and Germany for the development of the electrical industry, particularly with respect to the application of electric power to railroads. According to the Federal Power Commission, the Chicago, Milwaukee & St. Paul company "forwards twice as many cars at double the speed" on the division that has been electrified as compared with the others; power costs $\frac{1}{2}$ cent per kilowatt-hour—a figure that cannot be approached by oil- or coal-burning locomotives. In dozens of other industries the advantages are equally certain and equally important. Electricity is the modern form of power; its utilization as such has barely commenced. Until a practical means of transmitting current by wireless is perfected—a possibility that our electrical engineers declare is still remote—the electric-power industry should be the source of much comfort to the copper miner.

Mr. Ford and the Supply of Nitrate

"United we stand; divided we fall" is a motto that is being applied to the solution of many industrial and technical problems. Mr. Henry Ford has recognized the inter-relation of industrial efforts, and has made an offer to the Government to purchase and complete the United States nitrate plants and to lease the water-power plants in the South, using the excess power in his own business. A combination of this kind is often an essential to financial success; and it must be admitted that Mr. Ford is far-sighted. His proposal to the Secretary of War is reported to be as follows: He will take a 100-years lease on the Wilson dam, on the No. 3 dam, and on the electric-power plant when completed at a cost that has been estimated at \$28,000,000. He proposes to pay interest at the rate of 6% on this amount, and to amortize not only this sum but also the entire cost of construction over a period of 100 years. He offers \$5,000,000 for the nitrate plant and equipment, the lands, the steam-plants, and the other accessories, all of which cost the people of the United States about \$80,000,000. He proposes to remodel the large nitrate plant (No. 2), and to operate it for the production of fertilizer compounds in time of peace, and to equip it so that it will be ready for immediate conversion into an explosives plant in the event of war. He proposes, modestly we think, to limit the profits of the fertilizer plant to 8%, thus ensuring a relatively cheap nitrogen product for American farmers. The completion of the works will make the Tennessee river navigable as far as Chattanooga. The power developed will exceed greatly the requirements of the fertilizer plant, the excess being available, at a small cost per unit, for Mr. Ford's other enterprise or enterprises. Thus by disregarding nearly all the enormous first cost of the nitrate plant at Muscle Shoals and by combining two industries under one efficient management it may be possible to produce, at a reasonable price, in peace time, that essential prop of national existence, a suitable fertilizer; and, in war time, enough of the nitrogen basis for munitions to free us from dependence on Chile. Under the conditions that Mr. Ford proposes

to attack the problem it is obvious that the completion of the project will give the enterprise a tentative commercial value. United, the two industries may be successful; divided, and under dual control, one or both might be failures.

Last year the writer of these notes had the privilege of studying Mr. Ford's methods at Detroit, the conclusion reached being that the amazing success of his efforts had resulted from an ability to apply simple fundamental principles on a large scale. A few days before, at Saginaw, Michigan, it was noticed that a valueless brine was transformed into a valuable product by the utilization of exhaust-steam from a neighboring lumber-mill. Thus it was that two industries when joined were successful, whereas, if operated separately, at least one would have been a dismal failure. A few days later, in Ohio, the immense benefit of uniting industries was again noticed. In this case a supply of brine formed the reserve of an immensely profitable salt industry, profitable because exhaust-steam from a plant supplying power to chemical works, as well as to a large cardboard plant, was available, the three industries being operated under the same management. Mr. Henry Ford had the foresight to anticipate that the same principle may be applied to the production of 'tin Lizzies', fertilizers, and explosives.

The question now arises: How will Mr. Ford's scheme affect the cost of living, for that is the question of the day. We have urged in previous issues the need for adequate provision that will make us independent of Chile for the necessary nitrate supplies in time of war. In times of peace, however, how will the cost of Mr. Ford's fertilizer compare with the price of the Chilean product? The question is complicated but extremely interesting, for the economical combination of industries is, perhaps, more applicable in Chile than elsewhere, although it is difficult to convince nitrate operators of this fact. Perhaps this is because the nitrate industry has become enervated and languid, as a result of the ease with which the high-grade caliche could be selected from a deposit of such immensity, because of the high price of the product and the availability of efficient and cheap labor. Furthermore, the death of 'the goose that lays the golden eggs' is often the ultimate result of a policy of protection of monopolies, because of the restriction of trade that ensues. Mr. Fernando Benitez, whose kindly and appreciative comment on our recent editorial appears in the February (sic) issue of the 'Boletín Minero' of the National Society of Mining in Chile, takes issue with us with regard to our condemnation of the price-raising tactics of the Association of Nitrate Producers. Our comments, he avers, raise a laugh, as coming from a country where trusts had their origin. The point that we emphasized, however, was that the American companies in Chile, because of their allegiance to the laws of the United States, were not members of the nitrate 'trust'; and we opined that a greater interest in the industry on the part of American engineers and financiers would tend to break up the 'ring'. Mr. Benitez quotes the

United States Steel Corporation as an American concern whose tactics have been merely copied by the nitrate producers. To this we would demur, pointing out that the activities of the Steel Corporation are not monopolistic; it is not a trust, because it does not control the iron and steel industry of this country. Our national policy and our laws are against combinations in restraint of trade, and we still think that President Alessandri is taking the right course in breaking up the trusts, combines, and pools in Chile. The recent action of a group of exporters, who tried to corner the market for nitrate, resulted in the temporary collapse of the industry. It was the stupidity of such control that we tried to emphasize. In the present case it appears that the 'pool' will be hard hit, for it holds about a million tons of nitrate, bought at about £17 per ton. The result of its profiteering tactics has been that the industry has suffered, many of the producers having been obliged to suspend operations. President Alessandri has proposed to his Congress that the Government take control of the industry. The members of the 'pool', which is backed by the Rothschilds, are becoming nervous, and a loss of about £5,000,000 appears to be inevitable. The absence of any legislation against such combinations in Chile has resulted in endless complications. In the present case it seems that the members of the 'pool' are the agents and representatives of many of the operators and hold their votes in the Association of Producers. From this it would seem that the producers may be obliged, in part at least, to pay the piper. On the other hand, the Compañía de Salitres de Antofagasta represents a powerful and influential group of Chileans, who, though not in political agreement with President Alessandri, nevertheless realize that he is a strong and able man; and consequently they will be prepared to support him in any measures he may propose to help the producers and to save the key industry of Chile from the maw of the speculators. The election of Mr. Alessandri to the presidency of Chile marked a change of administration that was ominous; his program is one that is meeting with approval and support, especially from foreigners. He realizes that rings, pools, combines, and associations that operate in restraint of trade are inimical to the progress of Chile; he will, of necessity, take steps to place the nitrate industry on a firm basis by restoring open competition, and by prohibiting the selective mining of high-grade caliche. If he takes such action and if the Government assumes the control of the industry, money will be needed to finance the purchase and the shipment of the product. The 'pool' that has succeeded in nearly crippling the industry is essentially European; such a combination must be fought with something more than moral suasion. We wish the President of Chile good luck in his well-meant efforts. We foresee a healthy competition between the products of Chile and those of the factories in this country. It is to be hoped that Mr. Ford will be allowed to carry out his proposals; he has the capital as well as the organizing ability; the combination of the two should be of national service.

DISCUSSION

Iron and Steel on the Pacific Coast

The Editor:

Sir—I have read the article by Mr. Clyde E. Williams, in your issue of July 16, with keen interest. Mr. Williams has referred specially to the coking-coals of the State of Washington, notably the Wilkinson, Carbonada, and Fairfax districts in Pierce county, and while admitting that coke made from these coals has a high ash-content, he thinks coke can be made from this coal sufficiently low in sulphur and phosphorus to be desirable for use in the blast-furnace. I am fairly familiar with the Wilkinson and Fairfax coke, having used both in foundry-work, and I am very doubtful if a satisfactory blast-furnace coke can be made from this coal on an economical commercial basis.

Referring to his remarks on the coking-coals of British Columbia, I am compelled to take issue with him. Those of us who know the coals of British Columbia never considered the Cassidy coal as a coking-coal. On the other hand, the Cumberland, or what is known as the Comox, coal is an excellent coking-coal and beehive coke-ovens have been operating there for over twenty years. It is just a question of properly washing and properly burning in order to turn out a good coke, even in the beehive oven, and in a by-product oven there is no question but a first-class metallurgical or blast-furnace coke can be made from Comox coal, although the ash-content would be higher than Connellsville. Certain seams in the Nicola valley will coke in a by-product oven. This coal is high in nitrogen and from samples sent to England to test for by-products it produced values approximating \$9 per ton, plus 60% of coke as a good smokeless domestic fuel. This coal yields 30 to 40 gal. per ton of various oils and 15 to 20 lb. ammonium sulphate.

The Crow's Nest coal in East Kootenay is undoubtedly the best coking-coal on the Pacific slope. This district has been supplying the smelters with a good metallurgical coke for twenty years.

The establishment of an iron and steel plant on the Coast has become an absolute necessity, especially a blast-furnace plant for the manufacture of pig-iron. Quite recently I was commissioned by British and American interests to make a personal investigation of the market for pig-iron on the Coast. I interviewed practically every user of pig-iron, also the shipbuilding and engineering works from Vancouver to Los Angeles, and I am satisfied there is a market on the Coast for at least a thousand tons of pig-iron per day, and probably considerably more. The foundries in Oregon alone use 300 tons per day.

In discussing the question of pig-iron with the scrap-mill owners of San Francisco and Los Angeles, they assured me that the five mills would undertake to enter into a firm contract to take 500 tons per day. They are operating entirely on steel and iron scrap, but would prefer at least 40% pig-iron if they could secure it anywhere near the price of scrap, which was then \$32 per ton in San Francisco. The price of pig-iron was then \$65 to \$80 per ton. The prevailing price of pig-iron before the War was from \$27.50 to \$32.50 for Scotch pig, known as Eggleston No. 2, and during my thirty years residence in British Columbia, I have only once seen pig-iron under \$25 per ton.

Regarding the cost of producing pig-iron on the Coast from our native magnetic ores: In 1910 the Canadian Federal government sent out to British Columbia Mr. Lindeman, an eminent Norwegian mining engineer and metallurgical expert, to look into the cost of producing pig-iron by the blast-furnace method, and he estimated that notwithstanding the higher wages and cost of other material prevailing at the time, pig-iron could be produced from British Columbian ores at a cost not exceeding \$16 per ton. Siever also reported from \$12.50 to \$15. The high iron-content of our ores and their lack of impurities reduces the cost of producing pig-iron.

In a report that I received from Sheffield on a sample of magnetite ore from Vancouver island, they said crucible tool-steel could be manufactured from such ore at 8 shillings per ton less than from the best Norway ores, on account of the high iron-content and the lack of impurities.

Regarding competition from pig-iron made in China, I agree with Mr. Williams that we have nothing to fear from this source. They have not yet made a foundry pig-iron suitable for our market. Moreover, China will not only absorb all she can make herself, but will be a large importer of the products of iron and steel for the next fifty years at least.

Dealing with Mr. William's remarks regarding the total consumption of steel on the Coast, it is true that it consists of many different sizes and shapes without perhaps a large continuous consumption of any particular size, and I fully agree with him that it would be impracticable to construct and operate a single mill, to produce all this assortment of sizes and shapes, and that those products must be made for which there is a steady demand. He mentions tin-plate as a product for which there is sufficient demand to take the output of a modern rolling-mill, and states that the consumption of tin-plate on the Coast amounts to 150 tons per day. He is more than conservative in his estimate here, as the consump-

tion of tin-plate on the Coast is approximately 200,000 tons per year, and, in addition to this, approximately 100,000 tons per annum is exported to the Orient through Pacific Coast ports, but what we want first on the Coast is a blast-furnace plant whereby we can prove that we can manufacture the various grades of pig-iron from our native ores at a cost that will compete with the East and Europe. When this is accomplished, subsidiary companies will soon take up the manufacture of the various products of iron and steel. There already exists on the Coast open-hearth and rolling-mill equipment sufficient to take care of the merchant-bar market. What we lack is a mill large enough to roll ship-plates and large shapes and angles, and also rails up to, say, 56 lb. For the latter there is an ever-growing market.

Regarding the smelting processes that Mr. Williams mentioned: As I have already stated, a blast-furnace plant is what we want. In my opinion, there is a market on the Coast to justify the building of two 400-ton furnaces, one for the production of pig-iron, the other to be used in conjunction with an open-hearth furnace, in turning out steel billets by the continuous process. An electric furnace could also be considered in conjunction with the latter unit for the purpose of further refining, and, if necessary, making high-grade tool-steel and other high-grade steel castings. The other processes he refers to are more or less visionary.

One reason perhaps why an iron and steel industry has not been established on the Coast has been the scarcity of hematite ore, the iron deposits being largely magnetite. It has been maintained that these ores cannot be economically smelted in a blast-furnace without a large percentage of hematite to act as a flux and cheapen the cost of reduction. It is quite true that magnetites carry an extra atom of oxygen and therefore cost more to reduce to metallic iron, but I contend that the higher iron content of our magnetites, and their low sulphur and phosphorus content, more than compensates for any extra amount of fuel necessary to melt and reduce them. The magnetic ores of the Pacific Coast run from 55 to 68% metallic iron, with sulphur and phosphorus well within the bessemer limit, whereas the hematite ores of the Mesabi range and Lake Superior rarely run 50%, and are as low as 37% metallic iron. In reply to those who maintain that magnetites cannot be smelted without at least 25% of hematite, we know that in New York blast-furnaces have been operating for 30 years on 100% magnetite and on ores that are so low-grade and impure that they have to be concentrated by magnetic concentration, which also means crushing and sintering or briquetting before they can be used in the blast-furnace, so if it pays to smelt magnetic ores of this class in the East, surely it will more than pay to smelt our Coast ores, which do not require concentration and are practically free from all impurities, including titanium.

I congratulate Mr. Williams on the excellence of his article and thoroughly agree with him that the presence of an iron and steel industry on the Coast will stimulate the growth and development of the West. Its location

should be decided on economic rather than on political grounds. We, in British Columbia, believe we have more and better iron ore than is to be found either in Washington or Oregon. We also have an abundance of flux, and unquestionably we have the better coking-coal, and therefore we believe that somewhere on the east coast of Vancouver island would be an ideal site for such a plant. However, our American friends have the larger market for the product and it is just a question as to whether it is better to take the raw material to the larger market and manufacture there or put the furnaces near the raw material and ship the pig-iron to the market. The main thing is to get the industry started.

Vancouver, June 20.

N. THOMPSON.

Prospecting

The Editor:

Sir—The discussion on this subject suggests that the following speculations as to the history of the large body of colemanite reported to have been discovered in the extreme south-east corner of Nevada may be of interest to prospectors who have failed to acquaint themselves with the appearance of the non-metallic minerals. Some half a century ago, about the time (1866) when I piloted Governor Blaisdell's party across the desert from Silver Peak to Pahranaagat, a prospector reported that he had found an enormous outcrop of rock-salt in the neighborhood of the Virgin river, and described it as extending a great distance along the side of the canyon. Those of us who are acquainted with that mineral naturally discounted the story, and anyhow a deposit of salt in such an out-of-the-way locality was not a commercial proposition. Is it not more than likely that the prospector had found the outcrop of the colemanite and in ignorance of its true value was unable to negotiate a sale, and it became a forgotten story? I have a hazy recollection of mentioning the statement in my annual report as State Mineralogist of Nevada in 1867, but not having a copy cannot speak positively. It is lucky that the men who found the salt are dead and will never know how near they came to being millionaires. The occurrence of ulexite was first noted on the Nevada marshes on that memorable trip, which opened up southern Nevada to the prospector. The character of the country may be judged from the fact that when we left Silver Peak we were lost to the world for more than three months.

Seattle, Washington, July 5.

R. H. STRETCH.

The New Mining Law

The Editor:

Sir—"Pretty rotten" is the mildest criticism appropriate for that clause of the proposed new mining law that provides that mining records shall be kept in the district U. S. Land Office instead of a local recording office as formerly. Speaking for Alaska, the place for local public records is where they are accessible to the local public and not a thousand miles away where they are practically accessible only to agents and associates

of the Morgan-Guggs. How would the farmers of the States greet a proposal to remove the records of their title-deeds from the county-seat to the State capital or to Washington, D. C.? This clause illustrates how highly paid and highly respectable engineers earn their popular repute.

Kasaan, Alaska, June 29.

W. W. RUSSELL.

The Editor:

Sir—I wish to make a few comments on the 'Revision of the Mining Law' published in your issue of June 18. I have been prospecting and mining for 24 years and at the present time am the owner of two groups of lode-mining claims; on one group there is 842 ft. of tunnel and on the other group there is 200 ft. of tunnel. This work has been done by me alone with a single-jack.

First, why should the Mining and Metallurgical Society of America take such a deep interest in the welfare of the prospector and miner as to get up a new mining code?

"Sec. 5. Every full mining claim upon unsurveyed lands shall be located in the form of a square containing forty acres laid out on cardinal lines, conforming to the system of public land surveys."

The proper way to locate a lode-mining claim is to locate it on the strike of the vein, most of the mineral land that is left is in the rough mountainous regions, unsurveyed.

"B. Subject to limitations contained in this article, discovery of valuable mineral land shall not hereafter be necessary in order to locate and hold a mining claim."

Anyone with lots of money could hire men to go into the Forest Reserves and locate large areas, and by complying with C in the same section, they could set up a drilling rig, which is very easy for a man with large capital, and drill more than one hundred feet to make discoveries on each claim of 160 acres.

Under B., Sec. 6, it does not specify how or where the annual labor shall be performed and, of course, they could do it in the overburden or in the country-rock or any old place where they could do it quick and easy, or, in lieu of the performance of such labor, a sum computed at the rate of \$5 for each acre or fraction thereof may be paid each year, including the year of location, into the United States Land Office for the district. That is fine for the speculator and capitalist, but it would not develop a mine.

Section 7. Prospectors and miners who have held lode-mining claims under the apex law, which gives them the right to follow their vein to the entire depth, would find their veins cut off with a vertical side-line, as this section is conflicting and it would cause litigation without end.

Section 13, under B, is where the joker comes in. Where is there any unoccupied land belonging to the public domain outside the Forest Reserves that is worth \$10 per acre? Who wants to take land without limit as to aggregate area? Surely not the genuine prospector or miner! If this law should be passed by Congress, inside of ten years the biggest part of the Forest Reserves in the

western part of the United States of America, and also Alaska, would be in the hands of the capitalist.

Section 25. It would be a good thing to repeal Section 2341 and 2342 of the Revised Statutes, as they have caused lots of trouble by homesteaders filing over mining property, but Sec. 2322 and Act of February 11, 1875, relating to tunnel work, should never be repealed as they have done more to help develop the mineral resources than any law that can be put on the statute-books.

The apex law under Sec. 2322 seems to be a big bone of contention. I would suggest that it be amended as follows:

"Be it enacted, etc., that Sec. 2322 of the Revised Statutes be, and the name is hereby, amended so that the side-lines of all lode-mining claims shall run parallel with the dip of the vein to its entire depth; if there are any cross-veins on said claim the side-lines shall become the end-lines of said cross-veins."

Give me the good old mining code that has withstood the test of time and under which the mining industry of these United States of America has made the greatest progress that the world has ever seen.

Republic, Washington, July 5.

L. I. MUNSON.

Educating an Engineer

The Editor:

Sir—A good deal has appeared in print of late regarding the education of the engineer. It seems generally conceded that a too strictly technical course tends to a narrow outlook: the aim of the teacher should, it is thought, be to foster a broader vision, and a wider sympathy in the pupil. Admirable—especially if man lived longer and there was not so darned much it would be nice to know. Bacon could propose to master all the learning of his day without drawing down upon himself the ridicule of his fellows, but the man who should avow such an intention now would probably become a candidate for the foolish-house, his friends taking good care that he were safely ensconced therein and thus protected from himself.

No doubt, just as history is supposed to aid us in deciphering the future, so the experience of engineers of ripe age, if they would but set them down, ought to help the planning of a sensible curriculum. What did I study? How did these subjects help me in after life? What hours were well spent? What hours practically wasted? If the leaders of the profession would be at pains to ask themselves such questions seriously and then make known the answers, perhaps we should arrive somewhere. Just to start the ball rolling, in order that opinions of far greater weight may thereby be brought forth, I shall venture to give my own results premising that today education is conducted on far saner lines than a generation ago.

Mathematics is essential. French has come in useful in numberless instances. Latin may have helped a little, almost unconsciously, but was probably not worth the time spent on acquiring the little I once knew and have forgotten. German I never learned—sorry to say, for it

is more useful than French to the technical man. The 'teaching' of drawing, or music, unless the pupil has a real aptitude, is more or less humbug; you cannot turn out an artist or a musician unless the divine fire is present, and if it is, you cannot stop its exhibition—but an engineer hardly needs either of these accomplishments, though each may help him pass pleasant hours in even the most god-forsaken country.

As his profession will probably call him far afield, geography will come in useful; also some astronomy, at least sufficient for the latitude, time, and azimuth problems he may have to solve; and one of his closest companions during his dear old college days should certainly be a standard dictionary. It's really surprising how many eminent men cannot spell our most beautiful but puzzling language.

Looking backward, it seems to me the two subjects of study that have paid me best are Euclid and rugby football. Euclid is a wonderful mental training; even in planning the flow-sheet of a contribution to the press. Most good newspaper stories follow, unconsciously, no doubt, the general and particular enunciations, the construction, and, finally, the proof of Euclid's problems, as presented by the late lamented Todhunter, and other defunct worthies.

As for football, it teaches a lad to be active, to decide and act quickly, and is about the best training for the rough and tumble of every-day existence that I, at least, can think of.

This screed will, perhaps, attract the attention of those whose success lends weight to their opinion, and is, as will be conceded by all who honor me by reading it, more remarkable for what is left out than for what has been touched upon. But, in extenuation, Education is a big subject, and the thermometer at my elbow shows 95°F.

CHARLES A. BRAMBLE.

Winnipeg, Manitoba, July 2.

Book-Reviewing

The Editor:

Sir—The difference of opinion between Mr. Allen and myself over book-reviewing is one of proportion. My contention is that a review should give the average reader as good an idea as is possible of the book and what it specially has to offer. The review, in a paragraph or a page, should reveal the gist or heart of the book, if the reviewer has the ability to do such a thing, for it is not easy. By no means do I hold that adverse criticism, where warranted, should be omitted; in fact, the whole tenor of the reviewer's sentences should indicate his judgment of how well or how poorly the author has done his work.

Mr. Allen's opinion of book-reviewing, it seems to me, is that the reviewer should write for a much smaller audience than my suggestion indicates. He evidently would have the reviewer make little corrections and changes in the text for the benefit of the author when he prepares a second edition, much as if the author had

handed him the book with the request, "Would you mind reading this proof and marking any slips that you find"? Such a review obviously has not a general appeal and is interesting only to specialists, that is, only to those readers who have specialized in the same small field as has the reviewer.

As applying to Slosson's 'Creative Chemistry', it had seemed to me that Mr. Allen's review devoted too little space to the large virtues of the book, and too much space to carping details. The book covers a wide field, being a summary of much of the recent advance in chemistry, and is a work that should be represented correctly to thousands of the readers of the 'M. & S. P.'. There was a phrase in my letter that Mr. Allen apparently misunderstood; when I wrote "with all its faults", I referred to Wells' 'Outline of History', not to Slosson's 'Creative Chemistry'. However, there is one point on which Mr. Allen and I agree, namely, that book-reviewing is neglected or poorly done in America. It is perhaps due to lack of a proper critical faculty in a land where there is so much to be optimistic over.

London, June 23.

P. B. McDONALD.

American Trona Corporation

The Editor:

Sir—The Consolidated Gold Fields of South Africa, Ltd., has a reputation for probity and wise management of mining enterprises. This reputation, however, is likely to be injured as a result of the manner in which the American Trona Corporation is being handled. There seems to be no reason why this corporation should not be successful; yet year after year goes by with nothing accomplished.

In the monthly statements one finds obscurities and shifting classifications. It is, therefore, impossible to follow the business policies. Letters written to the New York office usually bring no information. One finds among other things money expended for the construction of a refinery on leased land at San Pedro and presently the work is given up, involving a large loss to the stockholders. No explanation is made of this action. It seems strange that careful management should have proceeded with this work to the extent of nearly half a million dollars without discovering that the plan was not feasible.

It is difficult to understand why the London authorities should attempt to manage these properties in California through a sub-office located in New York. Such an arrangement necessarily involves great expense and imperfect understanding of the work. An office in California would certainly seem to be in the best position to carry out effective management. The small stockholders cannot escape the fear that the present plan is inconsistent with their interests. It is to be hoped that the Consolidated Gold Fields of South Africa, Ltd., will have sufficient regard for their reputation not to allow carelessness to ruin the American Trona Corporation.

LEON J. RICHARDSON.

Berkeley, California, June 26.

THE PLANT AT CHUQUICAMATA

The Chuquicamata Enterprise—III

By A. W. Allen

The residue from the leaching process at Chuquicamata is removed from the vats by electrically operated grab-buckets of the clam-shell type. These are of six-ton capacity in the two bridges that span six of the leaching-tanks, and of twelve-ton capacity in the new bridge that unloads the three leaching-tanks which were recently constructed. These grab-buckets deliver the material to hoppers that lead to side-discharging cars, in which the residue is hauled to the dump by locomotives. These phases of operation are clearly shown in the accompanying half-tones. A residue sample is taken automatically by means of Vezin machines that are adjusted to cut a proportion of the flow of material to the dump-cars.

The solutions from the leaching-process are handled in a special type of vertical-shaft, boot, centrifugal pump, lined with antimonial lead. The thrust is held by special oil-pressure bearings; there are no stuffing-boxes. There are eight 15-in. pumps driven by 200-hp. motors, which operate at 750 r.p.m., and four 9-in. pumps, two of which are driven by 75-hp. motors at 1000 r.p.m., and two by 50-hp. motors at 950 r.p.m. These machines were manufactured by the Worthington Pump & Machinery Corporation, and have proved entirely satisfactory.

All the strong solution from the leaching-vats goes to the de-chloridizing plant, where the chlorine in the solution, usually amounting to about 3 gm. per litre, is precipitated by means of cement copper in agitators of a special type. The resultant cuprous chloride is allowed to settle, the decanted solution (from which about 80% of the chlorine has been removed) going to the electro-

lytic department. The cuprous chloride sludge is removed from the settlers by grab-bucket, and is dissolved in ferrous chloride, the resultant solution being passed through cylindrical mills that are filled with scrap-iron. The cement copper produced goes to settling-vats; the overflowing ferrous chloride solution from these is used to dissolve more cuprous chloride and is returned to the precipitating-cylinders. The cement-copper sludge is removed from the settling-vats by grab-bucket mechanism, and is returned to the de-chloridizing agitators. The cement copper, therefore, remains in the circuit, being used in the first place to precipitate cuprous chloride, and later being re-formed by precipitation with iron. About 20% of the cement copper is removed from operation each cycle and sent to the melting-furnace to be cast into soluble anodes for the electrolytic-cell house.

After passing through the de-chloridizing plant the solution is pumped to the main solution head tank. This is 90 ft. long, 60 ft. broad, and 12 ft. deep, and is constructed of reinforced concrete lined with mastic. From here the solution passes to the depositing-cells, of which there are now 784; these are 19 ft. long, 3 ft. 6 in. broad, and 4 ft. 10 in. deep. Each cell has 44 ferro-silicon anodes with five bars to the anode, each bar measuring 48 in. by 4½ in. by 1 in. The cathodes measure 3 ft. by 4 ft., and there are 45 per cell. The current-density used for copper deposition when operating at full capacity is 11.4 amperes per square foot of cathode surface.

The starting-sheets are made in 64 cells, of the same dimensions as those in the 'commercial' cells, the current-density used being 18 amperes per square foot of cathode

SUMMARY OF OPERATIONS AT CHUQUICAMATA

	1915	1916	1917	1918	1919	1920
Ore treated, tons	625,394	1,742,718	2,904,191	3,745,083	2,961,465	4,243,301
Copper content, %	1.71	1.71	1.76	1.64	1.62	1.54
Copper recovered, %	66.87	77.15	81.80	82.20	86.0	89.7
Copper recovered, million pounds.....	10.944	41.306	88.37	102.136	76.718	111.13
Net cost of copper, including selling and delivery, excluding depreciation and depletion, cents per pound.....	18.55	15.46	16.75	13.30	13.01	10.7

surface. The soluble anodes that are used in making the starting-sheets are allowed to be eaten away until about 20% of the copper remains. They are then replaced with new anodes; the scrap is sent to the anode-furnace for re-melting. The cells used for de-copperizing the wasted solutions are 46 in number, and are of the same dimensions as the others. The commercial copper sheets, or cathodes, formed in the cells weigh about 150 lb. apiece, and take about ten days to form. They are transported to the melting-furnace by means of a light railroad. The copper used for the production of the soluble anodes is melted in a 100-ton oil-fired reverberatory furnace, which has a hearth dimension of 26 ft. 3 in. by 11 ft. 6 in. The metal runs to a tilting ladle, and from there to a casting-machine, the final plate being 4 ft. by 2 ft. 11 in. by $1\frac{1}{4}$ inches.

There are three oil-fired reverberatory furnaces used for melting the cathodes and casting them into marketable shapes. Two of these furnaces have a hearth dimension of 41 ft. by 13 ft. 10 in., and a capacity of about 200 tons per charge. The third furnace has a hearth 50 ft. by 13 ft. 10 in. and has a capacity of 250 tons per charge. Wire bars varying in weight from 135 lb. to 275 lb., and ingot bars weighing 65 lb., are produced. The bars are tipped onto a conveyor about 20 ft. long and running at about 5 ft. per minute. This conveyor will carry up to 4 tons of copper bars, which are cooled by means of water sprays. The copper is delivered direct to box-cars that belong to the Antofagasta & Bolivia railroad, a narrow-gauge spur-line connecting the melting-plant with the station at Calama. The metal is shipped from Antofagasta, the freighting of copper and supplies being done in the steamers of a subsidiary company, the Chile Steamship Company.

Plans for the extension of the plant have been made, by which an ultimate yearly capacity of 300,000,000 lb. of copper is anticipated by crushing and treating about 35,000 tons of ore per day.

SOCIAL WELFARE. The establishment of an industry of considerable national and international importance in the heart of a desolate region in South America involves consideration of numerous problems of other than technical importance. The success of the mining and metallurgical side of the enterprise is essential, for without it the venture would be a failure. To make the industry an economic as well as a technical success, however, every detail of community life must be considered. Employees need more than their pay; they must be housed, they must be able to clothe and feed themselves, their children must be educated; facilities must be provided for the encouragement of adherence to whatever religious faith is dominant in the locality; surgical, therapeutical,

MECHANICAL HANDLING OF RESIDUE FROM THE LEACHING-PROCESS

and dental aid must be forthcoming when required; assistance must be given to foster physical fitness by means of games and exercises; mental enlightenment needs to

be fostered by means of libraries, reading-rooms, and night schools; amusement and recreation must be considered, for happiness and contentment are essential to honest effort.

After a period of observation that has involved travel in all five continents and residence in four of them, I feel justified in making comparisons of conditions at Chuquicamata with those that prevail in mining communities in other parts of the world, and I have no hesitation in saying that the Chile Exploration Co. is to be congratulated on setting an example that industrial concerns are usually too slow to adopt, especially mining companies that are operating in isolated districts. The results at Chuquicamata are all the more praiseworthy in that they involved enormous expenditures, in addition to careful planning. None of this cost has come from profits, for no dividends have been paid to date; conditions are far from normal in the mineral industry, and

MELTING-PLANT

the Chuquicamata plant is not yet operating at a capacity that indicates an exhaustion of ore-reserves that approaches an economically justifiable amount. The welfare work was carried to a successful conclusion before the enterprise was a financial success, and before the mine and plant were operating on an adequate scale. Not that the money spent in this connection was the result of altruistic ideas only; welfare work, provided that it is neither patronizing nor paternalistic, is generally an indication of sound business sense on the part of the company concerned. Men that are unoccupied, either during working or during leisure hours, are liable to be the centres of discontent of some form or other; and discontent should be avoided at all costs. This, doubtless, has been an important consideration in the scheme of welfare work that has been initiated at Chuquicamata.

Few engineers who have not undertaken the management of industrial enterprises in foreign countries can realize the difficulties in the way of retaining the individual members of the subordinate groups of an American staff for any length of time. At Chuquicamata, there has been a heavy turnover of minor company officials in the past, a condition that is much improved today. In the first place, a large amount of work that

was originally done by Americans is now in the hands of Chileans; the change has been satisfactory, for the citizen is, primarily, the most desirable worker in any locality, if he be capable. I have a high opinion of the Chilean laborer and mechanic; he is quick to learn and

HOUSES FOR STAFF EMPLOYEES

can be trained to observe the fundamentals of neatness and accuracy. Like others of our South American neighbors, he must be led rather than driven. He has his *vicios*, and unreliability is among them; but a large amount of mechanical work can be performed by Chileans of the better class. Many are experienced miners, and few are unaccustomed to the handling of tools. The common labor is drawn from a class that is exceptionally strong and sturdy; for manual work, especially under contract, they possess advantages over many other types.

The number of Americans, in proportion to output,

CHILEX CLUB

has steadily declined at Chuquicamata since the commencement of operations. Chileans are now used as engine-drivers, and as steam- and electric-shovel operators; they handle the drilling machines, as well as the large number of electric motors that move machinery of all kinds at different stages in the handling and treatment of the ore. The machine- and repair-shops are

maanned largely by Chileans; they perform a large proportion of the actual work in connection with the melting of the copper and the shipment of the bars and ingots. The trouble (if trouble it can be called) in connection with the employment of Americans, has therefore been reduced considerably, and because of the adaptability of the Chilean. The employment of any large number of Americans abroad will, in normal times, always constitute a drawback to successful operation in foreign countries. The United States is at a disadvantage in this respect, with regard to participation in foreign industry, in connection with colonization, and in the maintenance of an American merchant marine. Men go abroad as

HOSPITAL BUILDINGS

colonists or in professional capacities because the life at home lacks something that they can obtain by going farther afield. In some cases it is a measure of freedom they are looking for, or they need experience; in others, additional recompense is the controlling factor. But unless things are made exceptionally attractive for the young American, he sees no advantage in leaving his own country. He can get all the mining experience he needs in the United States; he can earn his pay at a rate that is the highest in the world. The American standard of living is no myth, as any manager will admit who has tried to satisfy the average American employee who is working in a foreign country. The thousand and one advantages of home life are missed; and, unless the normal rate of pay is increased largely, the employee is inclined to think that he has a grievance. With the majority of other nationals there is much to be gained and little to be lost by leaving home to take up a permanent and remunerative appointment overseas. Few Americans go to Chile or to any other South American republic with the intention of making the country their home, as so many Englishmen have done in the past. The fact that a large number of employees at Chuquicamata broke their contracts during the earlier years of operation is an undeniable fact; this meant a serious loss to the company, for the efficiency of any man reaches normal only when he is *au fait* with the work and surroundings; and the expense of engaging men in the United States and of bringing them to Chile has been considerable.

During three visits to Chile I have paid considerable

attention to the matter of the engagement of foreigners to work in the industries of the country, and I have come to the conclusion that the average American, in normal times, is too well-off at home to be satisfied with conditions in any other country, particularly where his own language is not spoken. There are a few notable exceptions, but the fact remains that the average American cannot conceive the idea of making his home among the people of a foreign country; it redounds to the credit of the United States that this is so; but, because of this, American expansion abroad will always be at a disadvantage, as compared with the efforts of other nationals. British prestige and influence in South America is almost entirely due, I should say, to the number of influential Britishers who are part and parcel of the national life in those countries. They may return, on rare occasions, to the land of their birth; but the hankering to do so is far less emphatic and far less frequent than it is with the Americans.

Apart from the feeling of preference for one's own country, State, or home town, I could see no justification at Chuquicamata for grumbling. The company has provided its employees with excellent houses that are rent-free. These are plainly but sufficiently furnished, the occupant having to pay only 10% of the value of the furniture per year, to allow for depreciation. Water, though expensive to obtain, is free; 50 kw. of electric power per month is supplied without charge, additional current beyond this amount being purchasable at a cost of $2\frac{1}{2}$ cents per kilowatt. A club-house that cost \$180,000

ADOBE HOUSES AT THE NEW CAMP

has been built and equipped for the benefit of all 'gold' or staff employees. For this the entrance fee is \$10, with monthly dues of \$2. It contains a fine swimming-pool, a theatre, bowling-alley, pool-rooms, ball-room, and library; it boasts of a real American barber, with complete impedimenta. A weekly paper, 'Chilex', is published in the camp.

The importance of welfare-planning work at Chuquicamata may be estimated from the fact that about 1800 dwellings and other buildings have been or are being erected, involving a total cost of about \$4,000,000. The company store carries an immense variety of goods, valued at about one million and a half pesos in normal times. All the employees' houses were built to standard pattern, at first of corrugated iron, and later of adobe brick, made from screened tailing, earth, and a small pro-

portion of cement. Type A houses have four rooms, a kitchen, and a bathroom; Type B houses, three rooms, a kitchen, and a bathroom. A few larger houses, for heads of departments, have six rooms, two baths, and a kitchen. Included among the buildings erected by the company is a Roman Catholic church, of artistic mission style, that cost \$45,000.

The hospital equipment is unusually complete, and consists of six buildings, with operating-rooms, separate wards for patients of different social grades, and for special cases, and a modern X-ray outfit. Dr. Shaw has

BAND-STAND AND CHURCH AT THE NEW CAMP

two assistants. The principal work at the hospital is in connection with minor and major accidents; pneumonia and appendicitis are not uncommon. The last-mentioned trouble seemed to be unusually prevalent, for which no reason can be assigned. Nine hundred cases of influenza were under treatment during the epidemic, from which there were only seven deaths. A dental surgeon is numbered among the permanent company officials, and a complete and up-to-date equipment is at his disposal.

Schools are provided for the children of Chileans and Americans. In the latter, Spanish is taught; but the number of American children at Chuquicamata is small. The Chilean school is under government control, and is staffed, partly at the expense of the Chile Exploration Co., with Chilean teachers; it is situated, together with the Roman Catholic church, at the New Camp, as it is called, where there is a large plaza and bandstand, and over a thousand small adobe dwellings for Chilean laborers. Every encouragement is offered, in the way of prizes and commendation, for cleanliness of house and attractiveness of garden.

In summary, I would like to say that my visit to Chuquicamata was as profitable in impressions as it was pleasant. The mining work being done is notable, not only on account of quiet achievement, but as indicative of a spirit of progressiveness that will undoubtedly make the property one of the world's principal producers of copper in the near future. The metallurgical practice

at the plant indicated careful planning and the absence of bias in the first instance, followed by capable control. The company appears to have done everything possible to make the employees contented and satisfied with their surroundings; in those cases where failure has resulted I feel sure that the cause lies not with the personnel or welfare departments, but is the result of temperamental influences over which they have little or no control, coupled with the fact that there is no natural beauty in the immediate country.

For the Chileans themselves I have a high esteem, but in making mention of them in connection with the work at Chuquicamata I realize that I must tread gingerly. The company has done a great deal, far more than it need have done on purely humanitarian grounds. This fact has been driven home on several occasions by company officials, who have made pertinent comparison between living conditions at Chuquicamata today, as compared with conditions that prevailed or prevail in other centres in the country. It is not easy to draw attention to such matters without causing offence; comparisons are odious. That the company has tried to set a high standard is patent; that Chileans have been quick to take offence, where none is meant, is also patent. The Chile Exploration Co. has been trying to make a home for Chileans in a barren part of their own country; it has helped them in every way to become good citizens. It has done this because of a real desire to bring contentment, and because the bringing of contentment is good business, and redounds to the credit of the organizer.

In conclusion, I would like to express an appreciation

SCHOOL FOR CHILEANS

of personal courtesies extended to me at Chuquicamata by Burr Wheeler, the general manager; B. A. Middlemiss, the assistant general manager; B. C. Leadbetter, the mine superintendent; L. W. Kemp, the superintendent of the reduction plant; Dr. W. F. Shaw; L. F. Sussick, of the welfare department; and W. R. Baseden, the company's agent at Antofagasta.

DEPOSITS of antimony exist in many parts of Mexico, and a considerable quantity has been produced, according to the U. S. Geological Survey. Output was increased largely during the period 1915 to 1918. No reliable data as to mine production are available.

Resuscitation of the Octave Gold Mine

By J. Nelson Nevius

After a successful period of operation during which it produced \$2,250,000 worth of gold, the Octave mine succumbed to mismanagement and was abandoned. It lay idle for several years, but recently has been re-developed so successfully as to give every promise of a profitable life for many years to come.

Octave is situated ten miles east of Congress Junction station in Yavapai county, Arizona, about half-way between Phoenix and Prescott at an elevation of 3250 ft. The town is on a patented mining claim and the company thus controls the little community. It is ten miles east of the old Congress mine, reputed to have produced \$12,000,000, which was mined to a depth of more than 4000 ft. on a dip of 30°. The geology and type of veins are identical in the two mines, and it is worthy of mention that there are similar veins in the district well worthy of development. The arroyos close to Octave have made a record as producers of placer gold; Rich Hill, Antelope and Weaver gulches being the main sources of supply. Much of the placer gold is coarse; I have seen a \$207 nugget taken from the Octave property, yet gold is rarely seen in the veins.

The name Octave is said to have originated from the fact that in 1897 eight men associated themselves to organize the Octave Gold Mining Co. A 40-stamp mill was erected, with amalgamation plates, concentration tables, and cyanide plant. Oil-fired boilers supplied steam-power for the mill, compressor, and two single-drum hoists. The plant was operated for several years and the vein was mined over a length of 2000 ft. along its strike and for nearly 2000 ft. on the dip.

In 1905 the property was sold to a Chicago stock-broker. At that time the bottom of the mine showed a strong vein but too low-grade to be profitable, and to the east the vein was cut by the Joker fault, as described later. Whether these unfavorable factors influenced the sale is conjectural, but they were never overcome by the new owners. Thus closed the first chapter.

Then began a period of stock-jobbing. The evidence underground, a mill ore-bin a third full of waste, and the correspondence left at the office, tell the tale of the wrecking of a good-mining enterprise. The climax came after the construction of an electric power-plant at Wickenburg, an 11-mile transmission line to Octave, and a complete electric equipment for operating the mine, the mill, and the town. This equipment is said to have cost \$150,000, but it was used less than two weeks. The company had no ore in the mine and neither cash nor stock in the treasury. Thus ended the second chapter.

Several years ago some of the bondholders engaged me to advise them whether the geologic evidence indicated a reasonable probability of successful re-development. My

report was favorable and resulted in the organization of the present Octave Mines Company, in which all former participants of record were invited to join on equal terms. H. C. Gibbs, of Boston, president, and Donald S. Leas, of Philadelphia, secretary-treasurer, have carried the burden of the financing. Before undertaking the heavy expense involved the company wisely engaged Wilbur H. Grant, of San Francisco, and later Mr. Miller, of New York. Both of these engineers reported favorably.

The new development was undertaken under my direction. The vein was recovered beyond the Joker fault by hand-drilling, and after drifting in good ore for several hundred feet a compressor plant, consisting of a Fairbanks-Morse Y engine and Sullivan angular-compound compressor, was erected, the camp was rehabilitated, and ore development was begun in earnest. The vein was recovered on the 850-ft. level of the Joker shaft, which corresponds to the 250-ft. level of the old mine. Reference to the accompanying map will explain the details. The 850-ft. level disclosed a continuous orebody for 730 ft., then encountered another fault, which had not been passed when work was suspended. Although this fault is a nuisance, it is not serious. The vein will be recovered beyond it, and the outcrop indicates that the vein is continuous for 3000 ft. farther within the company's property. Profitable ore has been found beyond the Joker fault also on the 600-ft. and 1000-ft. levels of the Joker shaft, and, with the exception of the 850-ft. level, all the working faces are now in ore, and further development will place more ore in reserve. The face of the 1000-ft. level shows a vein 52 in. wide assaying \$26.50. Within the boundaries shown on the map there is 40,000 tons of ore assaying \$14 per ton, with a gross value of \$560,000. The cost of the actual development of this ore was about \$55,000. There are 800 ft. of backs above the 600-ft. level to be developed, and if this ore goes no deeper than the bottom of the old mine, it gives 1500 ft. on the dip below the 1000-ft. level yet to explore. The map shows the relations of the new ore to the old workings and suggests the long life that may be expected on this one orebody. Then there is 3000 ft. of ground east of this ore, marked by a strong outcrop, yet to be developed.

The old mine has not been unwatered. Many miners have told me that the vein in the bottom is four to five feet wide, but low-grade. As the Congress mine was operated profitably to twice the depth of the Octave, there is sufficient encouragement to unwater the mine and sink deeper, but this is for the future.

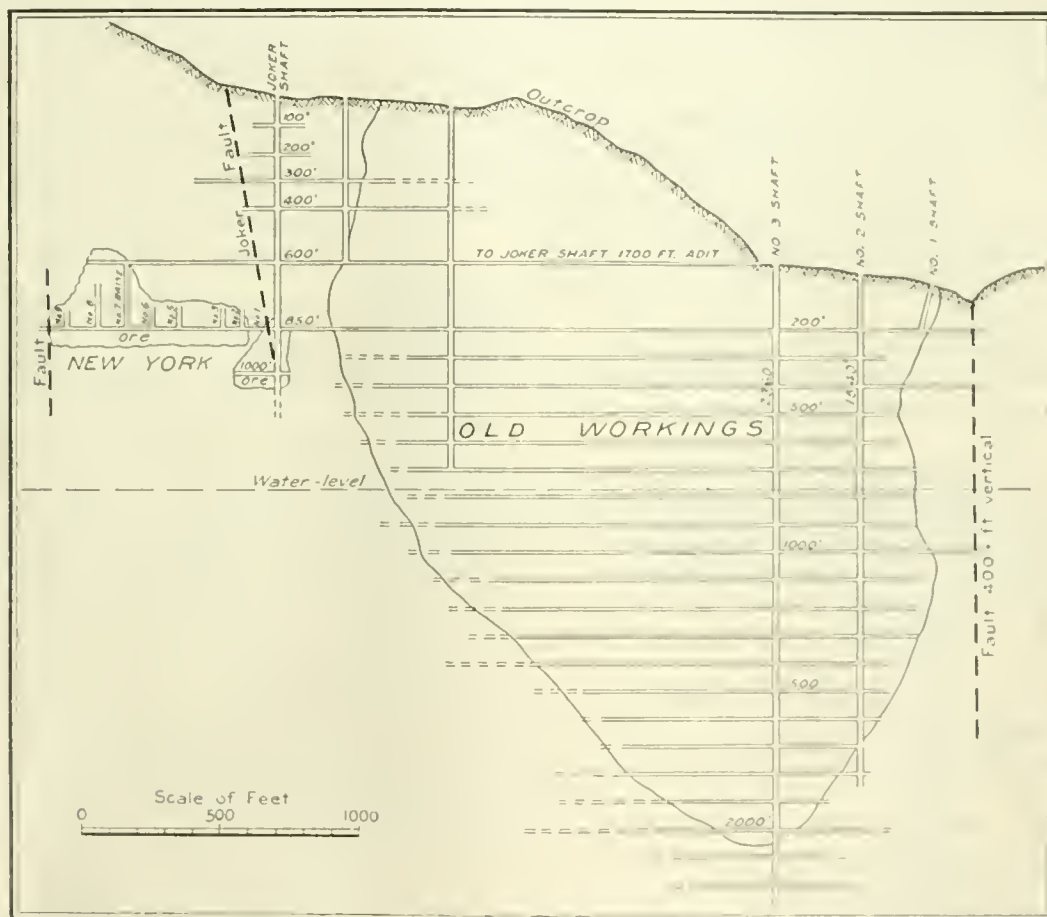

Development had gone far enough to justify a new mill when war conditions made it advisable to suspend operations temporarily. Mill-tests made by Hamilton,

Beauchamp & Woodworth indicate that a recovery of 96% can be made by a simple process. With the return to more normal conditions a new plant will be built using the old mill-building. Meanwhile no damage accrues to the mine by waiting until the bankers discover that gold is essential to our financial stability.

The Octave is an object lesson, showing that a mine may be abandoned before it is exhausted. When I first saw it the mine was a discouraging mess, both underground and on surface. The conditions were such that to the east the prospect was hopeless because the vein is cut by a profound fault at the base of the mountain. Some-

tempt, the displacement being 50 ft. to the right. More recent work has given some evidence of the existence at this point of two parallel veins about 50 ft. apart, and the Joker fault ends—like a tear part-way through a sheet of paper—at about this level. As exposed in the Joker shaft, the vein shows a sudden wave just above the 1000-ft. level, but no faulting occurs there, yet in the upper levels and on the surface the fault is unquestionable.

The Octave vein is one of several similar veins along the base of the mountains, which are composed mainly of a coarse-grained granite, such as encloses the Congress

SECTION OF OCTAVE WORKINGS

one had sunk a shaft said to be nearly 400 ft. deep and failed to get below the loose material of the wash. The bottom of the mine was not accessible because the mine was, and still is, filled with water to about the 800-ft. level. The west limit of the old mine was in the Joker fault immediately beyond the Joker shaft, and the work indicated frantic but unintelligent efforts to recover the vein.

A peculiar situation existed in that the evidence on the surface indicated a displacement of about 200 ft. to the left, where a strong vein shows near the top of the ridge, but the evidence underground equally strongly indicated a displacement to the right. As the effects of faulting were diminishing with depth, the 850-ft. level was selected and the vein was recovered at the first at-

tempt, the displacement being 50 ft. to the right. More recent work has given some evidence of the existence at this point of two parallel veins about 50 ft. apart, and the Joker fault ends—like a tear part-way through a sheet of paper—at about this level. As exposed in the Joker shaft, the vein shows a sudden wave just above the 1000-ft. level, but no faulting occurs there, yet in the upper levels and on the surface the fault is unquestionable. The Octave vein is one of several similar veins along the base of the mountains, which are composed mainly of a coarse-grained granite, such as encloses the Congress

vein strikes north-west and dips south-west at about 30°. In width the quartz varies between nothing and five feet. The average width of the new orebody is scant 30 inches. A thin selvage occurs on both walls, so the ore breaks clear of the walls, and both walls are hard and unshattered, timbering being unnecessary except where faulting has occurred.

The vein is composed of white quartz carrying 4 to 5% of sulphides, pyrite predominating, but galena, sphalerite, and chalcopyrite occur sparingly. About 60% of the gold is free and 40% is in the sulphides. It is noticeable that where the galena increases the gold increases. Although certain differences can be noted, the characteristics of this vein are almost identical with those of the veins at Grass Valley, California. One rarely finds conditions so similar in districts so far apart.

About 10% of the value is in silver, and both precious metals are rather uniformly distributed throughout the vein, assays rarely falling below \$5 or reaching as high as \$40. No coarse gold has ever been found in the Octave vein; and this is peculiar because the local washes yield numerous good-sized nuggets. Only rarely may any fine gold be seen in the ore.

As regards the delineation of the old mine on the accompanying map, the ragged line merely outlines the periphery: it does not mean that the entire area was stoped.

The reasons for recommending re-development constitute probably the most important part of this story and the most difficult to put on paper. Reverting to the time of the original examination, the favorable facts were:

1. Duplication of vein-structure and ore-deposition with those at the Congress mine, which was profitable to twice the depth.
2. Similarity of vein-type and ore-deposition with those of the classic veins of Grass Valley.
3. Continuation of vein-outcrop beyond the Joker fault.
4. An indefinite condition that made the Octave look 'right'.

The unfavorable facts were:

1. A successful company had sold the property, probably considering it about worked out; and a second company had spent much money on it and failed.
2. No chance for ore to the east. Bottom of mine inaccessible and further exploration at depth (2000 ft. on an incline of 30°) would involve very heavy expense.
3. To the west the vein was faulted and surface and underground evidence apparently was contradictory as to displacement.
4. Outcrop beyond the fault reasonably continuous, but almost devoid of pay-ore.
5. Old stopes showed the vein to be narrow and flat, with numerous though not large bodies of ore.

Reduced to print, the above brief does not make a strong case in favor of re-development. There are some things that can be recognized but not described, and I take refuge in No. 4 of the above list of favorable conditions.

Cadmium

There are several cadmium minerals, but none of them occur in quantities large enough to be called ores, states a U. S. Geological Survey bulletin. The cadmium of commerce is derived from zinc minerals and ores, in almost all of which it occurs in minute quantity, the ratio being about 1 of cadmium to 200 of zinc. Cadmium behaves metallurgically almost the same as zinc, and hence constitutes a fraction of 1% of almost all metallic zinc. The sources of cadmium that have been utilized are zinc ores treated by fractional distillation, lead-furnace bag-house fumes (the cadmium content of which is derived from the zinc minerals contained in the charge of lead ore), and residues from the purification vats of electrolytic-zinc plants and lithopone plants. The production of cadmium, either as the metal or as the sulphide, has been reported by the companies in the following list, which shows also the nature of the metallurgic plant in connection with which the cadmium plant is operated:

Producers of Cadmium in the United States in 1920

Company	Associated plant
American Smelting & Refining Co., Denver, Colo.....	Lead smelter
Graselli Chemical Co., Cleveland, Ohio.....	Chemical works
Krebs Pigment & Chemical Co., Newport, Del.....	Lithopone plant
Midland Chemical Co., Argo, Ill.....	Lithopone plant
U. S. Smelting, Refining & Mining Co., Kennett, Cal.....	Electrolytic-zinc plant
U. S. Smelting, Refining & Mining Co., Midvale, Utah.....	Lead smelter

Of these, the plant at Kennett, California, was reported to have made no output in 1920. The lead furnaces at the Globe plant of the American Smelting & Refining Co., at Denver, have been closed for some years, but stocks of cadmiferous residues remain from former operations, and more has been shipped in from other plants of the company. Several other electrolytic-zinc plants and lithopone plants save cadmium-bearing residue and have developed processes for recovering the metal, so that an extension of the uses of cadmium and an increased demand for it would result in additions to the list of producers. Several companies that produce cadmium-bearing residues sell them to the producing companies named above.

A NEW METHOD of determining surface tension is proposed by A. Ferguson in a paper that was read recently before the Faraday Society. Instead of measuring the height to which a column of liquid rises in a capillary-tube, external pressure is applied to force the level of the liquid to the bottom of the tube, this pressure being measured by a delicate manometer. Among the advantages claimed for this method are that it avoids difficulties due to variations in tube diameter and to variations in temperature in the capillary-tube itself; also the capillary-tube may be very short, which facilitates cleaning. The method is rapid in use, and it gives results which are in good agreement with those obtained by the best methods previously known.

According to the U. S. Geological Survey, 1% of the salt in the ocean would cover all the land areas of the globe to a depth of 290 feet.

Baja California and Oil Possibilities

By Victor H. Wilhelm

The area covered in this reconnaissance is mainly in the southern and central parts of the peninsula extending on the Pacific side from Cape San Lucas to Magdalena Bay, and on the Gulf side from the Cape to Santa Rosalia.

Baja California, or Lower California, consists of a narrow strip of broken mountainous land, 775 miles long and varying from 30 to 75 miles wide, and in general trends northwest-southeast. Its coast is characterized by long sweeps of gently curving bays, with intervening points enclosing oval basins, with outlying islands. The interior consists of a series of mountain ranges made up of recent volcanics, and submerged mountain masses that are an extension of the Sierra Nevada uplift.

The climate is remarkably equable, being little warmer than southern California, although much more arid. Large areas on the Pacific side have an annual rainfall of less than two inches, and the mountain areas average less than five inches. The entire area is a desert, with the exception of a few small valleys, where arroyos supply sufficient water for irrigation. The raising of cattle is the main industry, but considerable sugar-cane is grown where irrigation is possible. Most of the corn and beans, the staple food, are imported from the mainland. Pearl-fishing has been an important industry, but the beds have been worked out since the cancellation of the French concession.

The southern portion of the peninsula classifies itself naturally into two districts: (1) the area south of La Paz, on the Gulf, and Todos Santos on the Pacific, consisting mainly of granitic intrusives, gneiss, and schist, bordered on the east by a series of Tertiary and Pleistocene sedimentaries, and (2) the area running north from La Paz to Santa Rosalia, consisting of large deposits of limestone, sandstone, and volcanic tuff, forming mesas, with recent rhyolitic and basaltic flows.

The area situated south of La Paz consists mainly of granitic gneiss, probably of post-Jurassic age, cut by numerous dikes, of irregular size and continuity, the most prominent of which are syenite, diorite, and diabase. In places the original granite has been altered to hornblende, of a schistose character. This area consisted of an island during the Cretaceous period, as the area to the north was submerged during deposition of the mesa sandstone of Upper Cretaceous age. This island was of considerable extent and of an irregular outline.

There has been considerable mining at various times in this district. The mining town of Triunfo, situated 20 miles south of La Paz, is the site of the operations of the Progreso Mining Co., now called the Minas y Montes, of which Blamey Stevens is general manager. The properties of this company have been operating for over 50 years. The ore contains lead and silver, associated with

arsenopyrite, and is of a refractory nature. Two mills have been operated, using hyposulphite and cyanide processes after roasting. The various mines of the company are connected with the town of Triunfo by a narrow-gauge railroad. The mines contain 60 miles of underground workings, having been developed to a depth of 2700 ft. along the dip of a flat vein, averaging 35°. The orebodies consist of two well-defined fissure-veins in the granitic gneiss. One of these veins has been worked

MAP OF BAJA CALIFORNIA

for a distance of seven miles along the outcrop. The other vein, situated near San Antonio, extends continuously for a distance of five miles. The veins average from 3 to 7 ft. in width, and the ore, after sorting, averages 50 oz. of silver per ton. This company has had a total production of over \$16,000,000. The property is now under option to the Boleo company, which is financed by the French Rothschilds. The mines are not being operated, owing to a series of difficulties, the principal of which are the low price of silver, the wrecking of the mills by a local cyclone, and the fact that the properties were confiscated and looted by the Carranza government.

Labor is plentiful, efficient, and cheap, and the climate is healthful. There are numerous other small mines in this district, only one of which is operating on silver ore, and exporting arsenic as a by-product.

In the southern area there is a considerable extent of sedimentaries, bordering the Gulf coast, running from Buena Vista to San Jose del Cabo and extending inland for a distance of 15 miles to the sierras of the Cape region. Along the granitic and rhyolitic peaks are enormous deposits of unclassified and unconsolidated material, which Gabb states are the remains of glacial moraines, but signs of glaciation are totally lacking. These deposits cover a large area surrounding Miraflores and San Bartoleo. The bedded deposits occur almost in the attitude of deposition with a slight western dip due to an uplift along the Gulf coast. The beds present a west-facing escarpment, with steep dips along the edges, rapidly flattening in depth. Three distinct formations, lying conformably upon each other, were observed at this place. The oldest formation, probably of Upper Cretaceous age, consists of coarse indurated sand, in places with a greenish color, due to traces of copper carbonates, and also containing thin beds of crystalline gypsum, and some small seams of brown lignite. Several sulphur springs were observed seeping from this formation. Lying conformably on the gypsum are over 1000 ft. of fine-grained sandstone and clay-shale, including sundry beds of limestone made up of shell formations containing a large species of *ostrea*—probably of Miocene age. Seemingly conformable with the Miocene is a large series of Pleistocene conglomerates and granitic sands, which border the glacial moraines.

Despite the many exposures of tilted strata, there were no evidences of oil seepages, although some specimens of ozokerite have been found along the beach.

After leaving the granitic ranges south of La Paz, the entire character of the country is altered, the older igneous rocks are replaced by enormous deposits of sandstone, limestone, and massive conglomerate, forming mesas, or flat-topped ridges, and the backbone or higher portion of the peninsula follows the Gulf coast. These beds form rugged and precipitous escarpments along the Gulf coast, but dip gently to the Pacific side. Along a belt bordering the igneous rocks, running from La Paz to Todos Santos, the limestone in the sedimentaries has been altered along the contact to a fair grade of marble, which still shows the fossil contents of which it is made. This marble has been quarried for export, at Pescadero, adjacent to Todos Santos.

Traveling north, from the small town of Todos Santos along the Pacific coast, recent marine terraces, probably Quaternary, are observed. These terraces are of considerable extent near Magdalena Bay. At Point Cedros, 60 miles south of Magdalena Bay, the mesa formations of the Pleistocene, dipping westward at a uniform angle of 4°, outcrop along the coast. This formation was made up mainly of shell beds of marine origin, in which the fossil forms are well preserved. A section at this place consists of shell beds, containing *turritellas*, *olivas*, *patel-*

las, and *ostreas*, 60 ft. thick. Upon these beds are sandstone and volcanic tuff, more or less consolidated, underlying beds of volcanic ash, showing spicules of sponge forms. The surficial formation everywhere consists of massive conglomerate, made up of large boulders of eruptive material, loosely consolidated. To the eastward, in the higher mesas, these beds are penetrated and capped by deposits of volcanic origin, mainly trachyte and rhyolite. The Pleistocene is nowhere over 1000 ft. thick, and the volcanic flows average over 200 ft. in thickness. The Cretaceous can be distinguished from the Pleistocene by its unconformity, coarser grain, greater compactness, and the large number of boulders and pebbles embedded in it.

At Point Gasparino, 40 miles south of Todos Santos and 70 miles north of Cape San Lucas, on the Pacific side, there is a considerable accumulation of asphaltum and oil-residue on rocks of igneous origin. This deposit has attracted the attention of local residents for many years. The point of rocks is made up of granitic gneiss, and the oil has probably been liberated from seepages in the ocean to the north, and carried by the prevailing southern current, on the surface of the ocean, to be deposited on the north side of this point. At Point Cedros, on Pleistocene shell-limestone, a similar deposit was observed, but with no indication that the oil originated at this place. The U. S. Coast and Geodetic Survey has noted or received notice of the presence of large areas on the ocean covered with oil, which is probably caught on the projecting points of the coast. At Conejo, 60 miles south of Magdalena Bay, concretionary float limestone impregnated with oil was found at a considerable distance from the beach. There is a large deposit of carbonaceous shale at this place, but the impregnated limestone was not found in place. At Purissima, 40 miles north-east of Magdalena Bay, an oil-well 900 ft. deep was sunk by Mexicans in 1910, but they discovered only a considerable flow of heavily mineralized artesian water.

Inorganic sediments make up nearly the whole of the sedimentary beds in this district: they consist principally of the decomposed remnants of igneous rocks. Folding or flexure of the strata is entirely lacking, the only movement being the result of a gradual uplift along the Gulf coast and a consequent slight dip to the west.

Traveling north from La Paz along the Gulf coast, the line of the peninsula presents a ragged precipitous appearance, with definite west-dipping escarpments. The outlying islands consist mainly of rhyolitic flows, dipping westward conformably with the underlying Pleistocene shell-beds. At San Evaristo, 50 miles north of La Paz, bedded volcanic ash and tuff, impregnated with malachite, were observed. At Carmen island, lying east of Loreto, an oil-seep known to the inhabitants for many years was observed dripping from the overlying rhyolitic flow, probably through a fault or break in the volcanic material. Small boats have observed several other seeps at a distance from the land, such areas being supposed to be calm in the severest storms that sweep the Gulf. A similar seepage and residue of asphaltum has been discovered on the south end of Isle de la Guardia, in the

northern portion of the Gulf, not far from the mouth of the Colorado river. These evidences of the presence of oil undoubtedly come from the mesa sandstone, forced out from the porous formations up the dip by hydrostatic pressure.

The sedimentary formations of Baja California seem to be absolutely lacking in antilines or folds favorable to the accumulation of oil in commercial quantity. The oil probably has escaped for generations out of the open edges of the beds along the Gulf coast, as the formations are nowhere sealed. This would indicate that the oil has escaped as fast as it has accumulated. Diatomaceous shales such as are the source of the oil in southern California are entirely lacking. The prevailing vulcanism, which has prevailed during the sedimentation, is an unfavorable factor. The great extent and porosity of the beds would indicate that the oil has been rapidly replaced by water, and the oil forced out of the tilted edges of the strata. Drilling for oil where such seepages occur, through the sedimentaries back from the dip, would be useless, because no accumulation of oil could be expected.

Hints to Speculators and Investors in Mines

From a Cornish Book Published in 1857

1. Use great caution when a mine is represented as being capable of being commenced without machinery; or as being able to be wrought with an unusually small amount of capital.

2. Refrain from any mine proposed to be wrought by steam machinery with less capital than £5000, unless you are fully satisfied by your own *personal* examination. No mine ought to be undertaken without the possible resource of a surplus capital. Nine out of ten mines which have been cramped for capital have failed.

3. Be cautious when the Purser of the mine is a trader or shopkeeper. Mining capital is useful to extend private trade. Look to the Purser well, lest he look to himself too well; lend to him personally rather than indirectly.

4. Resident shareholders sometimes take shares in a neighboring project, if it will drain their own mine of water accumulated in it. Beware of projects got up by such gentlemen.

5. Avoid mines of which the traders in supplies have an agency, or in which their special friends are strong and numerous.

6. Avoid mines belonging wholly to non-resident shareholders, and which are left to the unchecked control of the Purser and Captain.

7. Look well to the registry and transfer of shares, if entrusted to the Purser alone, by means of entries in the cost-book only.

8. Avoid mines of any metal except tin, the leases of which are incomplete, or have been granted except by the sett and signature of the lord's agent in the cost-book.

9. The repute, skill, and character of the Purser and Captain of the mine you invest in, are quite as important to you as your skill in your own business.

10. Reference to an agent of uncertain character sometimes leads to a depreciation in the concern *you* are thinking of, and a recommendation of the concern *he* is thinking of.

11. What exactly suits the views of a mine agent, may not exactly suit yours.

12. It is far easier to put tin into a mine, than to get tin out of a mine; and it is more likely that you will lose £100 than gain £10.

13. To determine the number of shares you will take in a very promising mine, first consult your wife, then count your children, and lastly, calculate your household expenses.

14. It is just possible that the sample ores you see in London, or some other city, have come from any mine except the one projected, or offered to your consideration. Some samples have been known to serve for several mines.

15. As to foreign concerns, beware of wonderful reports and astonishing specimens. Not long since, some most rich masses of copper were exhibited in London, and a company projected. A keen agent, being sent out to report, found no such wonderful masses of copper, and hinted that more specimens had been *brought* to the spot by the hand of man than the hand of nature.

16. Before you invest, do not look over a list of mines whose returns have been extraordinary; but reckon up the failures. Be sure to be particular about these, as they will most concern you.

17. When you have invested, make up your mind to lose; and then any gains will be clear gains, and pleasant disappointments.

It is natural that an investing country, where, though its mineral deposits are meagre, metallurgical industries are as important as in Belgium, should have widespread interests in foreign mines. The capital of foreign mining companies (apart from coal) incorporated in Belgium may be placed at 73,181,000 francs, states a consular report. These companies exploit or control gold mines in South Africa and Australia, and operate zinc, lead, iron, and copper mines in Spain, Portugal, Sardinia, Tunis, Algeria, and Serbia. Among the largest of these mining companies are the Mines de Fer de Rouina (Algeria), capitalized at 8,750,000 fr., which operated profitably from its founding in 1908 to the outbreak of the War; the Société Minière Belge "La Productora y Coto San Antonio" (capital 7,500,000 fr.), holding lead and silver deposits in Spain, which did not show satisfactory results till 1920; and the Cie. Royale Asturienne des Mines (capital 6,000,000 fr.), operating, aside from Spanish coal mines, calamine and blende deposits in the Provinces of Santander and Guipuzcoa. Belgian capital has been widely distributed in foreign undertakings, the total amount of which may be estimated at 100,000,000 fr. The Banque d'Outremer and Belgian paper manufacturers have organized the Belgo-Canadian Pulp & Paper Co., with a capital of 4,500,000 fr. and an annual production of 35,000 tons of paper.

Our Anomalous Patent Office

By K. P. McElroy

"What's the matter with Kansas?" is an old question that never did receive a satisfactory answer until Kansas became prosperous and contented. Afterward, it needed none because it wasn't asked. Answering, or ducking an answer to, the same question about the Patent Office is becoming monotonous. The Office is prosperous enough, in the sense that it takes in more money than it spends; but it is far from contented. That it is in a bad way is shown sufficiently well by the number of employees leaving or about to leave. The Patent Office has always been, more or less, a sort of brooder or incubator for patent solicitors; and just now it is more so; much more so. It is full of cocoons awaiting butterflyhood. To use army slang, its morale is shot full of holes.

It is a serious and perplexing situation to American inventors and manufacturers to whom a strong and virile Patent Office, playing the game according to the rules, is a business necessity. What we are going to do about it is not evident. The Nolan Bill, so far as it related to the inside of the Patent Office, was treating symptoms and not a disease. Rehabilitation cannot be accomplished by the simple expedient of raising salaries, although it would help. It is unquestionable that the good men in the Office, of whom there are many, should receive salaries commensurate with their merit. But men of education and standing need something more than salary to keep them on the job; they require a certain amount of pride of place and dignity of position. Obviously, if a man is merely paid what he is worth and what he can command elsewhere and there are no other inducements, inertia is all that holds him. The cold fact is that, quite apart from salary, to the man in the Patent Office the outside looks more attractive than the inside. The Nolan Bill in no way cures this.

As I see it, it is to the work of the Smoot-Reavis joint committee, charged with revision and co-ordination of all government activities, that we must look for relief. That that committee will do something to the Patent Office is certain; that it will do much for it, is to be hoped. Also, it ought to be urged; and it is up to those interested in patent matters to do the urging. The committee is free to do what it considers right, for there is here no question of economy, elimination, or reduction. The Patent Office pays its own way; it costs the taxpayer, ordinarily, not one solitary nickel. And it must be big enough and equipped to handle whatever business comes before it.

Intrinsically, the Patent Office is a highly dignified institution, going back to the Constitution for its warrant for existence. It has been the birthplace of many of our great industries, and there is none that does not owe it something. Its records are the records of our national industry. A fire in the old near-white building would

be more terrible to industry than an army with Zeppelins. Its personnel is charged with duties requiring not only a knowledge of every branch of human endeavor, but of the principles of law as laid down in the statutes and countless decisions.

Actually, it is a mere bureau in the Interior Department bracketed with a miscellaneous lot of other bureaus, not to mention St. Elizabeth's Asylum and Howard University. What it is doing in that gallery, or in any executive department, I do not know, because it is in no sense an executive branch of the Government. It executes no orders of the President or of Congress—least of all, any by the Secretary of the Interior. Its employees are 'Examiners'; but Washington is full of Examiners. I remember one time when I was in the Patent Office and we were short-handed, the powers that were, to whom all 'Examiners' looked alike, detailed some from the Pension office to help out—with chaotic results. There is but little dignity in the title; and less official recognition than there ought to be. The head of the Patent Office is a Commissioner; but Washington is full of 'Commissioners' of all sorts—of pensions, of lands, of fishing, of Indians, of education, and what not.

Under the Constitution, the Patent Office is there to promote the progress of science and the useful arts; but it is to do it within the limits of certain statutes for that purpose made and provided. Therefore, its work is a blend or mayonnaise of law with science and technology. In the case of a patent, as with a contract, the wording is as important as the matter; what it covers depends upon what it says and how it says it, and not at all upon what it ought to say or ought to mean. A patent, to quote good old Dr. Squibb's statement, is a "law of the land"; and it is not to be granted without due consideration of all the legalities. When an application is filed, whether the invention be in determining the parallax of the fixed stars, in curing meat, or in sewing shoes, it is first referred to Examiners who are supposed to be expert in the particular art, familiar with everything that has ever been done in it, and prepared to understand the new thing; and to be able to apply their knowledge to it in view of the numerous controlling decisions in patent cases. This is a considerable requirement; but normally the Patent Office 'gets away with it'. The examining branches, of which there are about forty, are presumed to be manned by scientific and technical men of high standing, acquainted, among them all, with every branch of knowledge. The Examiners are the judges (jury maybe would be a better term) of the fact. From them an appeal lies to a Board of Examiners-in-Chief, members of which are appointed by the President with the consent of the Senate. Under the law, they must be persons of "competent legal knowledge and scientific ability". From the Board, a further appeal lies to the Commissioner in person, who, therefore, in this capacity acts as a court of appeals. General Dyrenforth, himself at that time an Assistant Commissioner of Patents, summarized the procedure neatly, albeit somewhat scurrilously, perhaps, in saying: "A case first goes to an Ex-

*Abstracted from the 'Journal of Industrial and Engineering Chemistry'.

aminer who knows the facts but not the law, then to the Examiners-in-Chief, who know the law but not the facts, and then to the Commissioner who knows neither".

In all its functions, the Patent Office acts as a tribunal to try to ascertain fact and law. It settles the question of ownership as regards certain alleged treasure trove between the inventor and the public, or between rival inventors, as the case may be. The Examiners are triers of fact, the Commissioner settles the law, and the Board tries both fact and law. In each and every activity, the Patent Office acts as an adjudicating body; not as an executive body. It is really a court, and should rank as such; not as a bureau of an executive department.

The importance of all this is that much depends, industrially, on the kind and quality of patents we are to grant; on the accurate working of our patent system. Bad patents, of which there are many, are as much of a public nuisance as good patents are of public benefit. All applications for patent should be as carefully scrutinized and examined as human ability will permit, and the interlocking team work on fact and law, provided for by statute in the Patent Office, should be at least as good as that on a baseball nine. Any patent may furnish the basis for litigation, often bitter and prolonged, and the more there is of this, the worse. Well-drawn and proper patents, like well-drawn contracts, seldom get into court; they are respected. A good patent on a good invention seldom needs litigation; the respective rights of the inventor and of the public have been settled in the Patent Office, once for all. On the other hand, a weak patent on something of importance usually does go to court and proves expensive for the owner, the industry, and the public at large. Frequently in such a case, where the patentee is lucky, the courts by judicial interpretation give the patent the form and meaning in which it should have emerged from the Patent Office in the first place. It is better for everybody that a patent, if granted, should be well granted. And to do this, it is necessary that the Office be manned and headed by competent men taking pride in their working together.

What the Smoot-Reavis committee on reorganization should do, in my opinion, is to lift the Patent Office from its lowly place in the Interior Department and make it independent, affiliating it with the judicial branches and not with the executive. I think it should be re-named the 'Court of Patents', and headed by a judge taken from the Federal bench; preferably a good crisp one. The Examiners should be high-class men, looking forward to a career in the Office, and with office conditions made attractive to them—much more attractive than they are now. All this will of course cost more money; but why not? It is not the Government's cash or the taxpayer's cash—it is the money of those doing business with the Patent Office. And those who pay the fees are entitled to get service for their money; service of a grade that they do not receive today.

The increase of filing fees provided for by the Nolan Bill is all right in and of itself, if it helps better the Patent Office. The present fees are not burdensome, nor

would the increase hurt anybody. But what's the use of providing more income to an institution that is already charging more than the value of the services it renders! Put the Patent Office on a better footing and then charge more. It is absurd to take the money of the inventors and use it to run a post graduate kindergarten for patent attorneys.

Alaska has produced about 972 tons of metallic tin, which has nearly all come from the placers of the York district at the west end of Seward Peninsula. Tin deposits, both placers and lodes, were discovered by the U. S. Geological Survey in 1900 and 1902. Developments began in a small way on placer tin in 1902 and the first dredge was installed in 1911. Since then two or three dredges have been employed in tin mining. A number of discoveries of lode tin have been made in the York district. Practically no tin has been produced from lodes, but lode developments have been under way since 1903. The only considerable underground exploration has been at the Lost River mine, where a mill is now under construction. Some placer tin has also been produced incidentally to gold mining in the Hot Springs district of the Tanana valley and in smaller amounts in other Yukon districts. Placer tin has also been found in the gravels of Yentna river, which is tributary to the Susitna. Though there has been systematic search for tin in Alaska during the last two decades, promising deposits have been found only in the York and Hot Springs districts. No new deposits of placer tin have been discovered in the York district in recent years, and there is no certainty that this form of tin mining will be continued there when the deposits now being exploited are exhausted. No tin placers which, under present economic conditions, will warrant exploitation for their tin alone have yet been found in the Yukon districts. When costs of operation are reduced, placer-tin mining may be developed in the Hot Springs and other districts. The distribution of the alluvial tin in this district also justifies the hope that tin-bearing lodes may yet be discovered. Meanwhile, the best hope of the continuation of Alaskan tin mining is based on the lode tin of the York district. The Lost River mine, in this district, is the only property sufficiently developed to justify the belief that it will soon become a producer, yet there are other deposits in the region which deserve prospecting. These facts do not indicate any large potential tin reserves in Alaska, but the wide distribution of the tin deposits gives hope of future discoveries. There is no evidence that the tin output will decrease in the near future, yet a large increase in production must depend on the development of deposits not yet discovered.

THE production of primary zinc from domestic ores in 1918, according to the U. S. Geological Survey, was 492,405 short tons, valued at \$89,618,000, based on the average selling price, as compared with 584,597 short tons, valued at \$119,258,000, based on the average selling price, in 1917—a decrease of 92,192 tons, or nearly 16%, in quantity and of \$29,640,000, or about 25%, in value.

Company Reports

CHILE COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Controls the Chile Exploration Co., with mine and mill at Chuquicamata, and power plant at Tocopilla, Chile.

Operating Officials: Burr Wheeler, general manager; B. Middlemiss, assistant general manager.

Financial: Operating revenue, \$17,711,020.80; operating cost, \$10,205,764.82; operating profit, \$7,505,256.98; other income, \$1,169,867.23; total income, \$8,675,124.21; charges against income, including interest on bonds of Chile Copper Co., \$3,590,280.18; balance of income carried to surplus account, \$5,084,844.03; charges against 1920 surplus, \$4,932,850.04; net surplus from 1920 operations, \$151,993.99; net deficit as at December 31, 1919, \$501,712.28; net deficit as at December 31, 1920, \$349,718.29.

Development: No further prospect drilling has been done beyond that mentioned in the last annual report. The ore-reserves as at December 31, 1920, were: 329,306,106 tons of oxidized ore, containing 1.91%; 151,000,000 tons of mixed ore, containing 2.98%; and 210,000,000 tons of sulphide ore, containing 1.84%; or a total of 690,306,106 tons, with an average copper content of 2.12%.

Mining Operations: Total ground broken during the year amounted to 2,134,665 cu. yd.; 627,595 cu. yd. of waste was removed from the benches, averaging 0.30% copper; total number of churn-drill holes drilled amounted to 764, with a total footage of 34,477 ft.; the total advance in blasting tunnels was 5919 ft.; since the beginning of the underground blasting tunnel development, a total of 93,340 ft. has been driven, of which 38,651 ft. has been blasted, and 54,689 ft. remains. Five new-type 103-C electric-shovels are being erected; when these are in service there will be a total of 9 standard electric-shovels, 1 Type 225-B revolving electric-shovel, and 10 Type 95-B steam-shovels on the property. Six 85-ton Porter side-tank locomotives have been added to the mine rolling stock, making a total of 32. One 1050-cu. ft. motor-driven air-compressor was installed in March, making a total of three of this type in service at the mine.

Milling Operations: 4,243,301 tons was crushed; the oversize on a 0.371-in. square-mesh screen was 13.54%, as compared with 19% for the previous year.

Leaching Operations: 414 charges were treated during the year, the average extraction of copper being 91.9%, as compared with 88.5% for the previous year.

Electrolytic Operations: The new 96-cell circuit was completed in December. The plant is now equipped with 894 cells.

Melting Operations: The third melting furnace was completed and started operations in April. The total production of copper during the year was 55,565 short tons.

General: The power plant at Tocopilla is operated exclusively on fuel oil; from the beginning of operations the company has relied on contracts with producers, who furnished the transportation, and delivered the oil at destination. This has not proved satisfactory, with the result that, during September 1920 a contract was made with British shipyards for the construction of two modern tank ships, each of 70,000 bbl. carrying capacity. One of these should be delivered late this year, and the other a few months afterwards.

In furtherance of the policy of discontinuing plant extensions until the universal disorganization of business conditions has improved sufficiently to give promise of the probable continuous sale of a maximum production from the 15,000-ton plant, the present condition of the work is as follows: (1) Designing work has been discontinued; (2)

the 18,000-k.v.a. turbo-generator set is under construction, the installation not being postponed, as it was needed to safeguard the power requirements of the present plant; (3) further work on leaching plant and sump construction has been discontinued; (4) the 55,000-bbl. fuel-oil tank at Chuquicamata has been installed, as an insurance against accident and to prevent irregular supply; (5) the water reclamation system has been postponed, there being ample water at the present rate of production.

HOWE SOUND COMPANY

Report for the year ended December 31, 1920.

Property: Company owns the Britannia Mining & Smelting Co., which owns the Britannia Power Co. and the Howe Sound Potosi Mining Co., which owns much of the stock of the Chihuahua Mining Company. Mines and mills in British Columbia and Mexico.

Operating Officials: E. J. Donahue, general manager Britannia company; A. L. Eaton, general manager El Potosi company.

Financial: Income, \$7,024,330.14; expenditure, \$5,177,167.00; balance forward, \$109,753.63; dividends, \$396,830; dividend payable January 15, 1921, \$99,207.50.

Development: Britannia company, 7078 ft. together with 5446 ft. of diamond-drilling; El Potosi company, 20,095 ft. of diamond-drilling.

Production: Tonnage handled by the Beach Mill during the year amounted to 710,450; yield amounted to 18,161,854 lb. copper, 6495.58 gold, and 101,505.07 oz. silver. From the Mexican plant there was shipped during the year the following: 120,158 tons of lead carbonates, with 13.95 oz. silver and 4.22% lead; 42,211 tons of lead sulphides, with 19.34 oz. silver and 6.98% lead; and 11,441 tons of iron sulphides, with 23.38 oz. silver per ton.

General: The concentrating mill at Britannia Beach was completely destroyed by fire on the evening of March 19. The power-house and adjacent buildings were saved. The company is protected by insurance and the construction of a new mill will be commenced as soon as plans and specifications can be prepared.

AMPARO MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mills at Etzatlan, Jalisco, Mexico.

Operating Officials: J. H. Howard, general manager; W. Howard, assistant general manager; W. R. Askew, chief engineer; C. F. Joyee, mine superintendent; A. F. Dick-Cleland, superintendent. Exploration company: W. Allison, shaft superintendent; J. M. Brown, assistant mill superintendent.

Financial: Income, \$1,748,381.59; profit on operations, \$231,756.79; net profit to surplus, \$114,416.91.

Production: 149,518 tons was milled, yielding 1,258,985 oz. silver, and 27,176 oz. gold. Operating costs showed a decline of \$2.48 per ton, as compared with 1919.

General: The Merrill-Crowe system of precipitation was adopted during the year and is in successful operation. It is expected that the saving in the consumption of zinc and cyanide in a year will cover the cost of the change. The fineness of the bullion produced is also improved.

INTERNATIONAL NICKEL COMPANY

Report for the year ended March 31, 1921.

Property: Mines and plants in Canada; refineries in New Jersey.

Financial: Total income, \$5,166,581.23; administrative and head-office expense, \$987,731.25; net income, \$4,187,849.98; profit for the year, \$2,029,699.83; dividends, \$534,756.

General: No technical details of the year's operations are given.

The Present Depression and Its Causes

By H. C. Hoover

*There is a feeling of some uneasiness and even of pessimism regarding the future of our foreign trade, in which I do not participate.

Our exports and imports during the last few months have dropped nearly 50% in value from the high-water mark of a year ago. Some of this decrease is due to the fall in prices relatively more than volume; some of it is the temporary world depression and some of it lies deeper.

In these times of troubled minds, we find much conflict of opinion as to the situation and its remedies. Some extreme groups insist that inasmuch as our exports comprise but 10% of our total production, therefore our foreign trade bears only this ratio to our economic life, and that, consequently, our true course is to forget it and to devote ourselves to healing our internal economic wounds. Other extreme groups consider that for our internal situation the only remedy is restoration of our export trade; they would undertake desperate measures to accomplish it. In either case we must not allow the present industrial depression to obscure our view. We have passed through several depressions since the Civil War and we have already turned the corner of this one.

The importance of our foreign trade requires but little defense. I may say in passing that our whole standard of living greatly depends upon our imports and that our exports are the great balance-wheel for our production. Exports are vital to the stabilization of our industries, of price-levels, of wages, and of employment. While our exports do cover but a small proportion of our total production, on the other hand they do comprise a large percentage of the production of certain industries. For instance, we generally export 20% of our wheat, 60% of our cotton, 75% of our copper, not to mention others. Unless we find a market for the surplus production of our great industries, we shall continue to keep some 25 millions of our people in reduced buying power. We might even drive them into poverty—during the many years that would be required to shift the whole basis of our internal production. Nor does a nation become rich by its exports alone—but by its trade.

While many of the causes of the present depression lie within our own borders, yet there may be no recovery from these hard times for many years to come, if we neglect our economic relations abroad. Even if we lower our vision of civilization in this crisis solely to our own selfish economic interest, we are yet mightily concerned in the recuperation of the entire world. The hard times that knock at every cottage door today came from Europe. No tariffs, no embargoes, no navies, no armies can

defend us from these invasions. Our sole defense is the prosperity of our neighbors and our own commercial skill. The recovery of our foreign trade can march only in company with the welfare and prosperity of our customers.

When we analyze the present foreign-trade situation, we find tremendous shifts in economic currents since 1914. Indeed, we find great changes still in progress. If we would guide our policies of production and of trade aright, we must keep these great changes constantly in mind. These profound alterations naturally fall into two divisions: The shift in the world's production and markets and the shift in the world's financial relations. They bear upon each other, and they affect our three primary groups of food, raw material, and manufactured goods differently.

There have been great changes in our own economic situation. We have not alone shifted from a debtor to a creditor nation; our capacity for surplus production in food and manufactures has grown enormously during the War until we have taken front rank of the world in foreign trade.

The direction of our trade has shifted greatly. During the last year about one-half of our whole foreign trade was with Europe, but of our exports to them 80% were foodstuffs and raw material; of our exports to states outside of Europe about 75% were manufactured goods. Europe in turn is our serious competitor in marketing of our manufactured goods to the rest of the world. We have enormously increased our imports of tropical and other commodities that we do not produce.

Since the Great War, the world, outside the fighting states of Europe, has gained mightily in wealth, in standards of living, and in consuming power. Even omitting the United States, it has gained something like 40 millions in population. The countries not directly affected by the War are indeed suffering from the general depression, but this depression with them is only the aftermath of the malevolent forces born of the past war booms. They have none of the deep economic wounds of the fighting states, and they will be quick to recover. During the War the productive capacity of these states, except possibly Japan, had no unusual increase because of their isolation through shortage of shipping.

One of the economic shifts that affects the whole world profoundly is from Russia. Russia bore much the same relation to western Europe before the War that the Mississippi Valley bears to our North-Eastern States. Russia was one of the great food bases of the manufacturing countries of western Europe, exchanging food for their fabricated products. These manufactured goods in turn were to some degree produced from our raw materials.

*An address delivered on July 12 at Boston before the National Shoe and Leather Exposition and Style Show.

Even at best it will be many years before Russia will have recovered. We are today the only great source of enlarged food production. Europe must and will draw from us a great proportion of food-supplies that she formerly drew from Russia. I see no basic reason why we should not continue to export approximately the same large volumes of foodstuffs that we have exported abroad during the past 12 months. This item alone at even present prices would be triple our pre-war food exports, and would represent the equal of more than 60% of our whole pre-war export trade.

Another great but uncertain shift in world forces will arise out of Germany. The reparation payments must have a profound effect upon the whole economy of the world. Germany is to pay outside her borders to the Allies \$500,000,000, plus 26% export-duty, or, say, a minimum of about \$750,000,000 per annum. Germany is left without much gold or foreign property, or foreign business earnings of consequence; therefore, these payments must be made mostly by the sale of manufactured goods outside her borders. But beyond the reparation payments, she must also sell goods abroad in the amounts necessary to buy her imports of food and raw materials. Any calculation based on the pre-war trade of Germany implies an enormous increase—perhaps more than doubling—of her pre-war exports. In view of the export duty and other payments, she must produce these goods for about one-half our production cost in order to take our markets. Such an increase in exports must be manufactured goods, and until the world consumption grows, these must be marketed in displacement of the goods of other industrial nations. We shall certainly feel the effects of this flow of goods that must be produced if she is to make reparation payments. On the other hand, Germany must take more raw material from us for this purpose. In any event, the crowding in the market of German exports will affect her immediate neighbors more than ourselves, for 80% of her market, pre-war as well as in the future, must lie in Europe itself.

The economic changes in the other combatant states in Europe obviously affects us also. The economic wounds given to them all by the War and peace will be long in healing. The sacrifice of skilled labor, of brains, and of property will require a generation to cure. The hates of many newly liberated states must cool slowly, and their many new borders check the free flow of commerce. Many of these states possess masses of people who have suffered from exploitation and tyranny for generations. Their extreme reactions of Bolshevism and socialism and nationalization are slowly dying out. Many governments have been unable to raise sufficient taxes to meet expenditures, and the ceaseless printing of currency carries destructive inflation. All of them except the enemy states bear the burden of greater military establishments than even before the Great War. All this must accumulate to decrease their productive power and to lower their standards of living.

In balance against this loss of productive power, their people over great sections are now coming to a full re-

alization that they must work harder than ever before and that they must export commodities for all that is in them, in order that they may make exchanges for the bare margin of life. Some of them will receive payments from Germany in relief of their tax-burdens. They are mobilizing the skill and intelligence of their people to their economic salvation with the same diligence that they were mobilized in war. The great manufacturing states are straining every device of science and thought to the improvement of their industrial processes, to the simplification of production, to the elimination of waste—that they shall make every reduction in production costs. In reinforcement of their marketing machinery, many of the governments are stimulating the consolidation of banks and of manufacturing concerns. Governmental and government-encouraged combinations are being created to control exports and imports to exploit foreign markets. They are seeking special concessions for development and trade throughout the world. Altogether these policies comprise a militancy in commercial expansion that compares with Elizabethan England.

Any improvement in European production of manufactured goods will favorably affect our market for those raw materials such as cotton and copper, where we possess the final supplies. In considering the demands for such raw materials, we must remember that the manufacturing countries of western Europe have lost for a long time to come any great markets in Russia and Turkey; the population of Europe as a whole has not the consuming capacity for manufactured goods that it had before the War and, therefore, we must expect less than pre-war consumption in the confines of Europe for their re-manufactured raw materials. But on the other hand, they will find, after this depression is passed, that the markets of the rest of the world are larger than before the War. I am confident they will gradually return to pre-war demand for our cotton, copper, etc. Fortunately, our producers have realized this temporary situation and have vigorously reduced their production so that they should eventually realize better prices than at present.

It seems to me that it was inevitable that the balance of the forces at work in Europe would improve their ability in competitive manufactured goods. Their production costs were bound to be lowered, both by better organized industry and by lowered standards of living. Some of them are today, through government subsidies, artificially low and will undoubtedly increase. If we analyze the effect of these forces on the market for our manufactured goods, either in Europe or in our much larger markets outside of Europe, we quickly find two directions in which we occupy a position of some security. The first is in those exports of lower production-costs which are the result of great repetitive production, which has its firm root in our enormous consumption. The second is in that large number of special manufactures in which the inventive genius and skill of our people have been developed beyond any country in the world. Your own industry of shoes and shoe findings is typical.

I believe we will recover and can hold our share of the market for these products after the present world depression.

As to our manufactures, containing a large element of labor cost, in which we do not enjoy special advantages, we must look out and take measures of our own. We can no doubt devise tariff measures that will protect our domestic market. But if we are to hold to our foreign markets in this vast group of our manufactures, and thus keep our people employed, we have several things to attend to. Fundamentally, we must get our production costs down. That lies only along the road of increased efficiency in our whole industrial machine. It means a willingness of our working people to put forth every effort that is in them, consistent with health, proper family life, and good citizenship. The surest road to a continued high wage, and the surest safeguard against unemployment, is to remove every restriction on effort. This must extend from our mines to the railways, to the factories, to the wharf, and to the ship. It means smaller margins of profit. It means that ultimately we must have much lower transportation rates. It means we must have better organized marketing machinery abroad under Americans themselves. It means the establishment of adequate short-time-credit machinery and much more care in foreign-credit risks than our merchants have shown in the last 12 months. It means elimination of the great wastes in industry. For instance, in the Atlantic seaboard area alone, by the development of these great water-powers and through economies by electrification generally, we could profitably save 30,000,000 tons of coal per annum if we had the courage to go at it. It means the Government must remove as quickly as possible those unnecessary domestic burdens upon commerce to which the Government is a party, by the reorganization of our tax system, the settlement of the tariff question, the reduction in Government expenditure through the reorganization of the Federal government, through reduction of armament and through reduction of Shipping Board losses and by the settlement by the Government of the outstanding claims of our railways. It means we must cease trying to drive American ship-owners off the sea with tax-paid shipping losses. We must carefully determine what particular trade-routes we will maintain in development of our commerce over a period of years, and let our merchants know them. It means the Government must provide such information to commerce and industry, from both at home and abroad, as will enlarge its judgment. It means we must extend scientific research into the problems of waste, the perfection of processes, the simplification of methods that are beyond the ability of one manufacturer acting alone, and we must co-operate with industry to perfect these things. I am confident we can hold our markets, our higher standards of living and of wage if we will all put our backs into it.

Overriding all these questions of production and markets is one of credits. Our whole financial relation to the rest of the world has greatly shifted. From a nation

owing some five billions of dollars to the rest of the world for moneys borrowed, the War has reversed our position so that the world, principally Europe, owes us today 13 to 15 billions of dollars, of which about 10 billions is due our Government. Before the War we had to export a surplus over our imports, and beyond this had to contribute, through remittances of immigrants, tourists, shipping, etc., great sums to pay interest upon our debts.

The reason for the piling up of this vast debt is, of course, that we have not only loaned money to the Allies, but have also since the War vastly increased the surplus of our exports, and the movement still continued to accumulate in our favor. Unless we would cease a large part of our war productivity with all the resulting unemployment and losses of such a cessation, we must continue to export in excess of our imports. Eventually the increase in our imports of tropical supplies, minerals, and commodities that we do not ourselves produce, together with the spending of tourists and the investment of surplus capital abroad, etc., should overtake our export balance and establish a proper equilibrium. In the meantime, if we would maintain our economic position, we must continue to give credits to buyers of our goods and if we should demand interest or principal on our established loans we would nullify any benefits of such credits. I may repeat that if today we stop giving more credits and demand payment of interest on debts due our Government, our exports will further decline, and the decline will find its interpretation in more unemployment among our own people and more displacement of our industries.

The natural effect of our continued surplus of exports is that our dollar is at a premium over even the most stable currencies in the world. Thus the cost of producing our commodities is higher than in any other country. This does not so materially affect the export of those commodities of which we hold a final supply, such as the food supplies and our raw materials, or those articles in the manufacture of which we have unique ability. It does, however, partly blockade our exports of manufactured goods in which we directly compete with Europe. Exchange itself is not the cause but the effect. It bears the same relation to trade that the barometer does to the weather. It is but an indication of the movement of commodities and credit. Our high barometer means we need more credits outward or alternatively we must send less goods out or take less goods in.

I may say, in passing, that I am confident that our debtors can eventually carry the debt due us with ease, provided they have the time necessary for the healing of their economic wounds, that they succeed in the reorganization of their fiscal policies so as to balance their government expenditure, and above all, that they secure disarmament and continued peace. Before the War the world carried a debt to a single European nation of twice the size of our foreign claims without knowing it, and with renewed growth of the world's commerce and wealth our debt will be no burden. Our problem is the difficul-

ties of our debtors during the few years until these blessings are attained.

My optimistic view that we will maintain the flow of our goods is based upon the assumption that we can wisely manage these credit problems. There is a general agreement that we must extend credit if we would market our surplus and upbuild our customers during these next few years of readjustment, but as to the methods there are many minds; there are those who would directly try to stabilize exchange back to parity; those who would create securities jointly guaranteed by the principal nations, either through international banks of issue, bonds, or currency; those who would extend credits directly or indirectly from the United States Treasury to buyers of goods, in order to stimulate exports; and also those who have confidence that the processes of business will find their own way out.

Attempts to bring exchange to parity or to create international securities of any kind are open to the objection that they involve an element of inflation and that they practically open the gates of credit from the United States without regard to risk, how its purpose affects us, or whether it really benefits the borrower. Loans from our Government direct to foreign governments or foreign merchants have a hundred objections and disagreeable entanglements which we learned well enough during the War. In all this maze of difficulty and the unsettlement over credits and debts, I would sum up that wisdom consists in knowing what to do next rather than debates upon perfection.

As necessary as the continued establishment of foreign credits are, if we are to maintain our large volume of export-trade, we should not over-estimate the amount needed for legitimate trade for re-finance and for reconstruction purposes. The amount is not so great as popularly supposed and will annually decline. I believe all trading states of consequence in the world can even now finance their imports of food-supplies. The stronger of them can finance their imports of raw materials. We are, indeed, importing very much larger quantities of tropical produce than before the War and our own consumption of these commodities will continue to grow. The margin of credits needed beyond our imports in order to keep commerce alive for the present are, first, comparatively short-term amounts to cover part of our exports of raw materials and the distribution period of our manufactured goods, and, second, constant re-finance of debts or interest already owed to us.

In summary, on the production and marketing side of our commerce, we can say that our food exports should remain on a greatly enlarged scale; that the demand for our raw materials should slowly increase toward pre-war amounts; that in respect to our manufactures we should be able to hold special fields of repetitive production and ingenuity; that we will need to make a fight to hold the markets for manufactured goods where we come more directly into competition with the European manufacturer, but that we can do it if we will work and apply our brains to it. On the financial side of our situation,

I do not believe our world credit situation is unsurmountable or that it requires extraordinary solutions.

I may repeat that we need to realize above all things, that even if we lower our vision of civilization in this crisis solely to that of our own selfish economic interest, we are mightily concerned in the recuperation of the entire world. There is an economic interdependence in the world that recognizes no national boundaries. The greatest jeopardy to the standard of living of our people is the lowered standards of Europe. Now that we have become a great debtor nation, we must learn that this great debt must be wisely directed so that we do not stifle both our own growth and the growth of others.

There are, indeed, many complexities arising out of our great expansion on productive power and our suddenly born creditor position. I do not need to say that we are confronted with a hundred difficulties, that we must be alert to steer our commercial policies against the winds of the world in an economic storm. We are suffering greatly in this immediate world-wide industrial depression. This depression is partly due to the War; it is partly due to our post-war boom, with its speculation, its extravagance, and its slackening of efficiency. The Government can help recovery by removing the obstructions to commerce and industry. But when all is done, the real cure for all depressions is courage and applied intelligence and the return to primary virtues of hard, conscientious toil and economy in living. On every side there is evidence that the vast majority of our whole nation is making again an effort in those directions equalled only by that of 1918, and the day some months ago when we entered this effort we fundamentally turned the corner of this depression.

We are not a nation of machines, and houses, factories, and railways. We are a nation of men, women, and children. Our industrial system and our commerce are simply implements for their comfort and happiness. When we deal with those great problems of business and economics we must be inspired by the knowledge that we are increasing and defending the standards of living of all our people. Upon this soil grow those moral and intellectual forces that make our nation great.

THE most active mining companies in the Belgian Congo are the Société Internationale Forestière et Minière du Congo, familiarly known as the Forminière, in which one-quarter of the capital is American-owned, and the Union Minière du Haut-Katanga, the ownership of which is divided between Belgian and English capital, states a consular report. The former is capitalized at 16,000,000 francs and the latter at 15,000,000. The Forminière specializes in extremely profitable diamond extraction. The Union Minière controls high-grade copper deposits. A mining enterprise independent of the Société Générale is the Géomines (Cie. Géologique et Minière des Ingénieurs et Industriels Belges), founded in 1910 by a combination of Belgian promoters and industrial engineers. Its concessions cover valuable deposits of gold, tin, and coal.

REVIEW OF MINING

NEW FLOTATION PLANT AT THE SMUGGLER UNION MINE IS TREATING 700 TONS PER DAY

The new flotation plant of the Smuggler Union Mining Co. at Pandora, Colorado, recently started, is a \$500,000 fire-proof steel and concrete building, equipped with the latest and best machinery known to the milling science. This plant is making a rich concentrate, which will soon pay for its erection. The capacity of the new plant, when entirely finished and all machinery running smoothly, will be larger than the one destroyed by fire in June 1920, by several hundred tons per day. The output is now about 700 tons daily and the machinery yet to be installed will raise it to 1000 tons each 24 hours.

The new plant uses the flotation process. It was designed by Walter L. Reid, the former superintendent, after repeated tests. The ore milled or finished in the plant will be drawn from three large properties: The Smuggler group of mines and the Humboldt in Marshall basin, and the Black Bear mines in the north fork of Ingram basin. Concentration and amalgamation is being carried on at the same time, as both the Smuggler and Bear veins carry gold, and the concentrates are rich in silver, lead, iron, and copper. The plant, which is designed for the treatment of complex ores, comes as near solving the problem as any mill in the country at this time. With this plant in operation in addition to the Tomboy and Liberty Bell, the ore shipments from Telluride will be larger than at any time in its history.

NEW GOLD DISCOVERY NEAR ANCHORAGE, ALASKA

Deposits of gold quartz reported to assay \$100 per ton have caused a rush to the district 39 miles south of Anchorage. The first find was made at Girdwood, on the Government railroad. Subsequently a dozen goldbearing lodes were uncovered within an area of about 5 by 7 miles. Some of these were exposed in the railroad cuts along Turnagain Arm. Engineers, who made a preliminary investigation, believe that the discovery is one of immense importance, according to dispatches.

BRITISH COLUMBIAN'S PROTEST AGAINST CANADIAN TARIFF REGULATIONS

Disadvantages under which the metal industry of British Columbia is laboring because of the "inconsistencies and injustices" of the present tariff on metals and minerals entering Canada are pointed out in a memorial prepared by the Board of Trade of Trail, B. C., and forwarded to the Canadian Minister of Finance.

Referring to the wire-rod business it is set out that this material now is imported free of duty "when manufactured by the importers in their own plants". If this situation is continued it is argued that the Trail smelting plant, capable of producing 15,000 tons of copper rods per annum, is placed under an unfair handicap. It is asked that rods be protected to the same extent as ingot copper, namely, 1½c. per pound. Without this "there is no chance of the expansion of the refining industry in British Columbia, and Canada will continue to pay foreign plants for refining copper used in making rods for Canadian consumption, as well as for rolling the

copper into rods after refining". The extension of the copper schedule in the tariff to include scrap copper also is sought because for many purposes it is as good as virgin; a great deal of that left in connection with munition manufacture had been dumped into Canada, and that this might be expected to continue in a lesser degree in the future. Scrap zinc and scrap brass, it is contended, should be subjected to a duty for similar reasons.

INCREASED PRODUCTION OF GOLD IN ONTARIO

According to preliminary estimates the gold mines of Northern Ontario produced approximately \$1,350,000 during the month of June. This compares with estimates of a little under \$1,300,000 in May and \$1,084,345 in April. The production for the second quarter of the year, therefore, amounted to around \$3,734,345 and is the highest quarter in the history of gold mining in Ontario. This compares with \$2,953,036 during the first quarter of the year, during which time the mines were handicapped through lack of hydro-electric power. In spite of this difficulty the first quarter of the year, the half-year just closed resulted in an aggregate gold output of approximately \$6,687,381. There is the additional important fact that the second half of the year has commenced with gold being turned out at the rate of at least \$1,350,000 per month, which would indicate a production of \$4,050,000 for the quarter that includes July, August, and September.

RICH PLACER DEPOSITS IN NORTHERN MEXICO

Ralph L. Van der Naillen has returned from Mexico with sundry valuable concessions granted by President Obregon and glowing reports of the prospect for developing and exploiting rich gold-placer deposits along the rivers of northern Mexico. He is quoted as saying that he explored the Sinaloa river for more than 200 miles, finding gravel of "paying" grade so abundant as to tax "human credulity". On the Fuerte river he found gravel that equaled the richest ever found in Nevada and Butte counties in California. Van der Naillen declares that the Mexican government, as regards himself, had acted in the highest good faith throughout his negotiations.

AGREEMENT TO ARBITRATE ENDS STRIKE AT GRASS VALLEY

The strike and lockout of miners in the Empire, North Star, and Idaho-Maryland mines at Grass Valley ended on July 15 when the Mine Workers' League voted to accept arbitration and the miners returned to work. Resumption is proceeding as rapidly as possible. The mines were practically closed on July 1 when the miners refused to accept a reduction of \$1 in the daily wage-scale and only pumpmen and engineers remained at work. The League at that time censured the mine operators for announcing the new wage-scale through the press before giving notice to the workers. A 50c. cut would have been acceptable, the League voted later, and, when the companies refused to accede, a threat was made to withdraw the pumpmen and hoist-

engineers. Both sides had been determined not to recede from their original stands, and it was only after arbitration was agreed upon that the miners decided to return to work. An arbitration board to represent the operators and the more than 600 workers will be named and their award will become retroactive to July 1. The loss of miners' wages due to the strike is estimated between \$60,000 and \$70,000.

ARIZONA

Globe.—Water, to the amount of 660,000 gal. per day, is to be furnished the city of Globe by the Old Dominion Copper Mining & Smelting Co. at a charge of 12½c. per 1000 gal. Eight thousand feet of 8-in. supply main will be built from the mine to connect with the city mains. The city water-system, on which \$400,000 has been spent, has proved inadequate in present drought conditions. Water from the mine is better than that from the city wells.

CALIFORNIA

Auburn.—The shaft of the Rising Sun mine, near Colfax, is to be deepened and exploration at lower levels started. During 1920 a new hoist, compressor, and pumps, together with a 10-stamp mill and two concentrators, were installed. The mill operated for five months, but the ore on the upper levels has been exhausted. New development will be commenced at once.—George Carmack is erecting a drill on his property, formerly known as the Pacific Blue Lead mine. He has been prospecting the claims for two years, and has recently decided that a drill is the most economical machine for continuing the work.

Bridgeport.—An important mining transaction is the transfer of the Success and Success No. 2 claims, under bond and lease, to Elmer M. Green. John H. and C. C. Hayes, who have been prospecting the claim, found considerably high-grade ore, but were unable to finance the opening of the property on a large scale.

Lewiston.—L. Gardella, of Oroville, is making rapid progress in the construction of his dredge which will work the goldbearing ground on the Paulsen ranch, which Gardella recently purchased.

Melones.—In June the Carson Hill Gold Mining Co. milled 15,500 tons of ore, an increase of 300 tons over May and the highest monthly crushing since beginning operations. On the surface just back of the present workings in the Morgan mine, the company is mining, by glory-holing, a deposit which years ago returned over \$3,000,000 in pockets of free gold. It is producing 125 tons of ore per day from this operation, at a cost, including everything, of \$2.50 per ton, and the ore averages between \$4 and \$4.50 per ton.

Quincy.—Harry Barnes has uncovered an 8-ft. vein of high-grade bornite ore at a point 14 ft. below the surface in a prospect shaft on his claim near the Engels mine.—The Reimiller Copper Co. is preparing to do additional prospecting by means of diamond-drills. Since last fall the company has proved the existence of three distinct orebodies in its property north-west of the Engels mine.—Diamond-drilling on the property of the Feather River Copper Co. has disclosed various bodies of high-grade copper ore containing both bornite and chalcopryrite. Ore also has been found in the main working-tunnel, approximately 2000 ft. long. H. E. Bush is manager of the property.

Redding.—An aerial tram is being constructed to connect the Hornet mine of the Mountain Copper Co. with the Southern Pacific railway. The lower terminal of the tram will be at the new town called Mathewson, the name being that of one of the directors of the company. Eventually the Iron Mountain railway, which now carries the ore, will be abandoned. The company is building a first-class highway from the mine to Mathewson, so that cumbrous freight, that

cannot be moved on the tramway, will be hauled by auto-truck. Lloyd C. White is the designer of the tramway. The company has petitioned the Board of Equalization of Shasta county to reduce the valuation placed on its Iron Mountain mine, for purposes of taxation by the county assessor. The Iron Mountain mine is distinct from the Hornet property.

COLORADO

Aspen.—Development of the orebody opened in the Hope tunnel is progressing. A second raise is being driven 35 ft. south of Raise No. 1, and an orebody 5 ft. wide assaying 25 oz. silver and 25% lead is exposed. Native silver is present. A larger force of miners is to be employed; a concrete boarding-house is under construction.

Breckenridge.—A find of silver ore in a vein 18 in. wide has been made at the surface on the June Bug. Three tons taken out by trenching assays around 400 oz. and a 2-in. streak 1000 oz. per ton.—The concentrator at the Pennsylvania mine of the Liberty Leasing Co. at Argentine has resumed. Ore is hauled to the plant by auto-truck.

Cripple Creek.—The June output from the Cripple Creek district, curtailed by cessation of freight-traffic by the railroads during the flood period, totaled 36,381 tons, with average value of \$10.02 per ton and gross bullion-value of \$365,171. Of this tonnage the Golden Cycle mill, that has treated all ores shipped from the district since the shut-down of the Pueblo smelter, handled 22,000 tons with an average value of \$14, total, \$308,000; Portland G. M. Co.'s Independence mill, 13,181 tons, \$4.20, total, \$55,371; and Lincoln M. & R. Co.'s mill, 1200, \$1.50, total, \$1800.

The Queen mine in Eclipse gulch, owned by the Queen Gold Mining Co., controlled by the John T. Milliken estate, is to resume operations. The shaft is to be sunk an additional 250 ft. to the 950-ft. level and arrangements made to cross-cut the ground on the level of the Roosevelt deep-drainage tunnel, at about 1700 feet.

Georgetown.—The Capital Mining & Tunnel Co., while not operating on company account, is planning to start up its compressor plant to furnish air to lessees. One set in Bruce territory has opened up a rich shoot of lead-silver ore, and a shipment sent out last week is estimated to be worth \$100 per ton. The pay-streak is 18 in. thick of nearly solid metal.

Leadville.—Due to the closing down of the Pueblo smelter the Arkansas Valley smelter is arranging to blow-in a fourth furnace.—Activity is reported from the Twin Lakes section. The Fidelity G. M. Co. operating the Fox property at the head of Black Cloud gulch has opened a 6-ft. vein from which the ore is averaging around \$80 per ton, chiefly gold. A streak in the vein samples 10 to 15 oz.; this ore is closely sorted and sacked.—Operations have been resumed on the Livermore in Red Cloud gulch, and on the Texas Creek holdings of the Yale Mining & Utility Co. The Harland mill at Twin Lakes has been purchased by this company and is now being remodeled and new machinery installed.

Silverton.—The Ariadne Corporation, Alfred B. Iles, managing director, has resumed work on the Ariadne in the Cement district, five miles from Silverton. The property has been under continuous development for two years past and silver orebodies are developed. Shipments will commence as soon as a graded trail can be made to the mine. An aerial tram is to be constructed for movement of ores to the shipping point on the railroad.

Ward.—Electric power has been installed at the Ogden mill on the American Gold & Platinum Co.'s property. Tests of the 'Ogden' process are reported to have made high recovery of the fine gold and platinum in the company's ores.

IDAHO

Coeur d'Alene.—In the Sterling Silver property on Big creek the lower cross-cut tunnel has been driven nearly

600 ft., passing through several stringers of quartz carrying silver.—According to Charles G. Taylor, manager for the Giant Ledge Mining Co., half a dozen mines will be added to the list of shippers from the Coeur d'Alene just as soon as the reconstruction of the railroad up Pritchard creek is completed. The reconstruction of the road will reduce the haul from Bear creek considerably. In about two months the Paragon will be ready to operate. It is 16 miles from a railroad, but will be within two miles of the line when rebuilt. The Jack Walte is a shipper in spite of its long haul, which will be eight or ten miles less when the road is built. The Monarch has been hauling its concentrates 15 miles. The railroad will be at its door. The Giant Ledge will in all probability finish its mill this fall and will be ready to commence shipments.

At a meeting of the American Commander Mining & Milling Co., recently held at Wallace, the following board of directors was elected: Patrick Johns, New York; J. A. Glowe and Harry Kingsbury, Mullan; and J. L. McCormack and Herman Marquardt, Wallace. Operations in the tunnel have been suspended while machinery is being installed. Two or three feet of carbonate ore was exposed when work was suspended in a drift from the upper tunnel.

The lessees of the Western Union Mining Co. have shipped ore having a gross value of \$54,454 since November 19, 1920, according to reports recently made by the board of directors.—The Sidney mine on Pine creek in the Coeur d'Alene has started shipping. More than 175 tons of high-grade ore has accumulated during the exploration of the vein for a distance of 240 ft.—It is now believed that the Imperial Mining Co. has found the vein for which it has been searching. The cross-cut was run 500 ft. without striking anything that looked like the vein, although several stringers of good ore were cut. Recently the management went back 200 ft. from the face of the cross-cut and started to drift west on a promising looking stringer. In 15 ft. the stringers widened out to four feet of vein with crystallized lead scattered through it. Assays from some of this ore returned 26.7% lead.

MICHIGAN

Houghton.—Copper continues to move out of the Lake Superior district. One steamer has just taken a cargo of 900,000 lb. of Calumet & Hecla, Copper Range, and Quincy metal, half from each smelter. This shipment included 300,000 lb. of Calumet & Hecla copper for domestic buyers, business previously reported.

At the Quincy smelter preparations are being made for the overhauling and modernizing of No. 3 furnace. It will be enlarged to a capacity equal to that of No. 5, or 150,000 lb., which will give Quincy two of the largest and most modern furnace-units in the district. No. 5 furnace is just about completed. It has been partly in commission for some time. Like No. 5, No. 3 will be served by automatic casting-machines, electric cranes, and trolley dipping system, which will result in a lessening of operating costs and greatly increase Quincy's capacity to meet any unusual demand for metal. Quincy is not smelting as much ore as is being shipped to the smelter and large quantities are being accumulated. Quincy's refined metal stocks are low, the smelter output keeping just a little ahead of demand. Quincy continues to yield a lot of mass copper. No. 2 shaft is still the largest producer of mass. No. 6 and 8 also are notable in this respect.

But little timbering and few repairs have been necessary in the Osceola property since its shut-down. In the North Kearsarge branch electric pumps are now handling the inflow of water from the Wolverine. Three pumps are in operation, one on the 17th level, one on the 31st, and one on the 36th in No. 1 shaft. A number of small pumps formerly in use in No. 3 shaft have been stopped and it is no longer necessary to use No. 1 shaft for bailing purposes. The use

of electric pumps will greatly lessen mine-costs in this branch. Costs took a jump when Wolverine stopped pumping in the lower part of its mine in May of last year, necessitating an opening between the two properties in order that the water might be pumped through North Kearsarge.

Preliminary work on the draining of a dam near No. 2 shaft of the Allouez mine has been started by Calumet & Hecla. The water has been seeping through into the mine, adding to pumping troubles. A ditch, a half mile in length and 10 ft. in depth, also will take care of surface water that has been getting into Ahmeek and Kearsarge. A large dredge employed by Calumet & Hecla in draining territory west of the South Hecla shafts will be used in this work. It is surface water that gives the most trouble and the drainage ditches will result in a considerable reduction of costs. Calumet & Hecla has successfully drained a swamp several miles in extent to the west of the South Hecla branch, taking care of water that formerly found its way into the conglomerate shafts, burdening the pumps and necessitating the operation of ballers.

MONTANA

Butte.—Development on the 2300-ft. level of the Colorado mine by the Davis-Daly company indicates a large body of copper ore assaying 15 to 16% copper. The vein continues to be from five to six feet wide. At its Hibernia mine the company is sinking the main shaft from the 600 to the 800-ft. level.

A two-foot vein of good silver ore is being followed by the Butte & Plutus company on the 400-ft. level. The ore is believed to be part of the Norwich vein system.

Dillon.—According to Henry Auerbach, president of the Silver Spray Mining Co., the necessary capital has been raised for resuming work at the property 20 miles south-east of here. A hoist, compressor, and other necessary machinery will be provided to sink the shaft below the 80-ft. level.

Elkhorn.—Additional men are being employed by the Boston & Montana company in the erection of its 1000-ton mill. The large gyratory crushers that will do the original crushing have arrived at the plant.

NEVADA

Cherry Creek.—Joseph Whitford is operating the North Mountain and Wild West mines under lease from Thomas Oggers and others. Two shipments of ore recently sent to the smelter at Midvale, Utah, netted \$4000. Plans are being made to operate a five-stamp mill.—Herman Bress and Charles Johnson shipped five tons of gold-silver ore assaying \$68 per ton.

Ely.—The Boston & Ely Consolidated Mines Co. is steadily developing copper ore of smelting grade on its property one mile west of town. The main workings of the Boston & Ely company, on Ely Northern ground, consist of a tunnel driven 636 ft. north from the canyon and of about 500 ft. of cross-cuts driven from it in the copper-bearing limonite body which was entered at 420 ft. from the portal. A 420-ft. shaft was sunk 290 ft. to water-level, and four levels driven from it at the 50-, 100-, 200-, and 280-ft. points. A raise above the shaft was driven 150 ft. to the surface. The total development to date amounts to about 2700 ft. The mine is equipped with semi-Diesel compressor, hoists, and other machinery.

In addition to the discoveries on the Boston & Ely on ground originally owned by the Ely Northern company, considerable bodies of zinc, lead, and copper ores are now being developed on ground owned by the Ely Calumet company, operated under a lease by A. D. Meyers and associates. This ground is situated about a mile and a half east of the Ely Northern claims.

The Board of Examiners for hoisting-engineers has

issued first-class licenses to six applicants. The former practice was for the person seeking a license to operate a mine holst, to make written application to the Board of County Commissioners, filing therewith an affidavit as to his past experience. The new law requires him to appear before the Examining Board in person and demonstrate his ability to operate a hoisting-engine.

Goldfield.—The first shipment of high-grade ore from the Donald and Giles lease on the Florence contained 1900 lb. assaying 142½ oz. gold per ton, with a small silver content. The ore is widening slightly as a stope is advanced above the 110-ft. level of the Reilly workings. After more than 15 years the work of Donald and Giles brings to light how Ross Woodward, now leasing in an adjoining block in the same vein, actually shot into the Donald and Giles orebody, which would have led him to the Reilly bonanza, and missed it because he did not sample the ore. Woodward then abandoned the block and it was leased by Reilly, who made a production that was estimated at more than \$500,000 gross. Woodward drifted for 20 ft. parallel to the Donald and Giles shoot and within 18 in. of it. He drilled two "pop holes" into the side of the drift and these holes, it is now revealed, entered the ore, and Woodward could have had a fortune had he panned the broken material.

Hornsilver.—A. I. D'Arcy of Goldfield and San Francisco associates have signed an agreement to buy for a price reported to be \$50,000 the lease of J. W. Dunfee on the Orlean mine, and have acquired Dunfee's option to buy the property for \$10,000. The Orlean contains at a depth of 380 ft. from the surface, or on the 580-ft. level of an inclined shaft, what is considered to be the most important orebody found in southern Nevada since the early days of Goldfield. The shoot, 5 to 15 ft. wide, is 130 ft. long as exposed now and there is no indication of the end. The average value of the ore is more than \$30. The plan of Mr. D'Arcy, it is said, is to block out the ore and erect a mill after this has been done, using the organization of the Columbia Divide in financing the project, and later changing the name to Columbia Hornsilver. The orebody on the 580-ft. level is one of two important shoots exposed in the mine, the other being on the 200-ft. level of a second shaft. This orebody, 100 ft. long, is reported to have an average value of \$20.

Stonewall.—The Yellow Tiger has moved from Goldfield one of the 30,000-gal. water-tanks formerly used by the Goldfield Consolidated. This will be used by the Tiger for the storage of oil for that and other companies in the surrounding region. The cost of Diesel-grade oil can be reduced from 27½ to 10c. per gallon by buying in large quantities, according to Gordon M. Bettles, manager.

Virginia City.—A transformer-house at the Belcher mine in Gold Hill was destroyed by fire recently. The fire will delay work on the Belcher mine of the United Comstock Mines Co. The Belcher shaft is one of the four through which the United Comstock company is operating and the delay will come through the shortage of electricity until repairs are completed.

UTAH

Alta.—According to M. R. Evans, manager of the Columbus-Rexall company, during the two weeks period ending July 9, 63 carloads of ore were sent to the Midvale smelter. The first lot, consisting of 141 tons, gave net smelter returns of \$4005. All of this ore was mined during the past winter, and stored at the property. Physical conditions in the mine are satisfactory. —At the Wasatch Mining Co.'s property 25 men are employed. —The South Hecla Mining Co. is now shipping an average of 50 tons of silver-lead ore per day, according to George H. Watson, manager.

Eureka.—Most of the mines in this district closed for three days—July 3, 4, and 5—to give their employees a holiday. Shipments for the week ending July 9 totaled 156 carloads, or approximately 6260 tons. The Tintic Standard shipped 47 cars; Chief Consolidated, 36; Grand Central, 12; Iron King, 9; Eagle & Blue Bell, 8; Victoria, 7; Iron Blossom, 7; Swansea, 8; Colorado, 8; Dragon, 6; Eureka Hill, 2; Mammoth, 1; Yankee, 1. During the same period the Tintic Milling Co. received 28 cars of ore from the Horn Silver mine at Frisco, Utah.

During the current year the mines in this district will be called upon to pay over one-half of the total taxes of Juab county. The valuation of real estate, personal property, etc., is \$8,176,114, while the valuation placed on the mining companies, which includes their net proceeds, totals \$8,727,181, making the total assessment for the county \$16,903,295.

A well-equipped surface plant has been installed at the Diamond Queen property, consisting of a 60-hp. boiler, an Ingersoll-Rand compressor, and a hoist. A bunk-house, boarding-house, and office building have been completed. The shaft is now at a depth of 180 ft.; it will be sunk to 500 ft. according to Richard Campbell who is in charge of the work.

E. J. Raddatz, general manager for the Tintic Standard company, announces that two new roasters are to be installed at the company's mill in Warm creek. A tonnage of 140 tons is being handled by the seven roasters now in operation at the mill. The two new roasters will make possible the treatment of 190 tons. This can mean only one thing—that excellent work is being done at the plant. About 14 oz. silver, 3½% lead, 2% copper, and some gold is contained in the ore now being sent to the mill. A shipment of 18,700 oz. of silver bullion was sent to the mint recently from the mill, and since then two shipments of bullion have been sent to the Salt Lake smelters for refining, on account of the repair work being done at the mill refinery. Each of these lots contained about 22,000 ounces.

Tooele.—Announcement is made that work will be resumed at the Buckhorn mine, about 50 miles west of here, in the Dugway mountains. The directors feel confident that the source of the rich gold-silver ore found on the surface years ago by Sam Gilson will be discovered. It is stated that the ore shipped from this property by Gilson and his associates during the summer of 1891 was some of the richest ever discovered in Utah. The ore was principally a chloride of silver, with some free gold found in the matrix. Shipments made at the time are said to have averaged from \$200 to \$1100 per ton. On account of its inaccessibility, the property has remained idle all of these years.

WASHINGTON

Northport.—Success is attending the efforts of Harris & Coring in their development of the Gus Mackl zinc deposits. The shaft has been sunk 180 ft., disclosing a continuous vein. Several carload shipments have been made and a concentrator is being installed for the separation of the lead and zinc. Mackl discovered zinc-carbonate ore on his farm by accident in the course of plowing. The vein has a maximum width of 7 to 8 ft. and at the surface its chief metallic content is zinc. Lead has appeared in increasing volume as depth was attained. The ore is reported to contain 40 to 50% zinc, some lead, and four to five ounces of silver per ton. The property was acquired a year ago on a bond and lease for \$30,000.

Republic.—The Lone Pine and Surprise mines, at Republic, owned by the Day Brothers, shipped 15 carloads of ore, or about 450 tons, in June, and 30 tons is being mined daily. The San Poli mine, in the same district, is shipping 50 tons of ore per day.—It is reported that the Day Interests are to develop their properties to a greater extent

than ever before and that they will erect a plant for the treatment of their own ores. There also is talk that a custom-plant is to be built for the district.

BRITISH COLUMBIA

Alice Arm.—The Consolidated Homestake Mining & Development Co. has started to develop the Homestake group, on the upper Klitsault river. A body of low-grade ore, carrying copper, gold, and silver, has been exposed on the surface, and it is purposed to develop this at depth. The work is in charge of C. H. Gerhadt, who is now establishing a camp on the property. This property was bonded some years ago to the Granby company; drilling and other development work was done, but at that time the Dolly Varden railway had not been built, and the Granby company officials considered that the development did not warrant purchase, owing to the lack of transportation facilities. Like the

ducer of this district will not be reopened this year unless there is a marked improvement in the prices of silver, lead, and zinc.

MEXICO

Durango. John A. King has filed on the old La Aguilarena gold-silver mine which comprises twelve claims in the Santiago Papasquiaro district. P. de la Peña and associates are erecting a reduction plant near the station of Patos for treating the ores of the mines in that vicinity. It will be completed and ready for operation within a few weeks. — General Miguel Leveaga of this city has recently taken over the San Andrian mines; he is preparing to develop them. — A. R. Hunter has taken possession of the San Juan silver mines in the Santa Maria mountains at Velardena and is putting them in shape for production.

Mexico City.—According to an official government report,

Guanajuato, Mexico

Dolly Varden, to make a profitable mine under normal metal-price conditions, a concentrating plant will be necessary.

Gerrard.—The Provincial government is building a wagon road through Fire Valley for the purpose of opening the promising mining district in the neighborhood of Lightning Peak. At the Waterloo mine, in this district, some high-grade silver-lead ore has been developed.

Kitchener.—The tunnel at the Sullivan Larson group is being pushed forward, and it is expected that the orebody will be cut within the next two months. — A pump driven by gasoline engine has been placed in the shaft at the Leadville group, on Goat river and Leadville creek. The mine is said to be developing well. — Work has been started on the C. P. Hill claims, in the mountains near here; development is in charge of G. A. M. Young and W. R. Muir.

New Hazelton.—W. G. Norrie Lowenthal of the Delta Copper Co. says that the company will make no attempt at production during the existing conditions of the copper market, but the development of the mine is to be continued, principally by diamond-drilling. A drill for the purpose was taken to the mine last September. — It is understood that the Silver Standard mine, which has been the principal pro-

the production of different minerals in Mexico for the twelve months ending June 30, in kilogrammes (2½ lb.), was: gold, 23,370; silver, 2,068,938; copper, 46,056,900; lead, 121,434,066; zinc, 14,363,057; mercury, 77,229; antimony, 1,572,376; graphite, 2,911,529; tungsten, 34,917; tin, 1588; arsenic, 1,198,806; and manganese, 838,624. The average monthly production of gold is placed at 1965 oz., and that of silver at 170,824 ounces.

One of the remarkable phases of the mining situation in Mexico at this time is that there are nearly 30,000 mines subject to forfeiture by the Government for non-payment of taxes. Forfeitures of this kind are being constantly made and many valuable properties have been acquired by new denouncements for a 'mere song'. It is shown by the records of the Bureau of Mines that there are approximately 70,000 mines in Mexico, including developed and undeveloped properties. Many of these mines were owned by Americans and other foreigners who were forced to seek safety by leaving the country during the revolutionary period. It is only recently that many of them have ventured to return and resume work upon their respective holdings. In many instances the owners of promising prospects have been unable

financially to meet the tax assessments against their mines and have been compelled to witness their forfeiture.

Saltillo.—Antonio Mazatan, of this city, is exploring the Parrena group of mines situated near the village of Parras in the Atajo mountains. It is practically an undeveloped district where some high-grade lead-zinc ores have recently been discovered.

ONTARIO

Cobalt.—At the annual meeting of the Mining Corporation of Canada, on June 29, J. P. Watson, president, stated that the new orebodies discovered on the Buffalo property would make a valuable addition to the ore-reserves, now estimated at 1,350,000 oz., and, added to those of the other properties, brought the total up to 2,181,923 oz. as of December 31. The policy of the directors was to go ahead at full speed so long as operations were profitable, but they would not sell silver at a sacrifice nor submit to inefficient labor at excessive wages. The Flin Flon copper property in Manitoba, in which the Corporation had acquired a controlling interest, contained 16,000,000 tons of assured ore, and additional possible and probable ore amounting to 9,000,000 tons.

Goudreau.—The Murphy gold claims have been sold to Toronto interests represented by A. R. Porter. Operations have been begun with J. Diampre, former manager of the Croesus mine, in charge. Stripping is being done and a shaft will be sunk immediately.

Kirkland Lake.—The Bidgood is drifting on the 300-ft. level and is in ere. Extensive lateral work will be done to ascertain the extent of mineralization before continuing the shaft to deeper levels.—The annual report of the Kirkland Lake for the year ended May 31 showed an operating profit of \$34,990, as compared with \$24,499 for the previous year. The production amounted to \$277,007, as against \$107,071.—A long diamond-drill hole has been run at the 400-ft. level to find the position of a vein showing at the surface and several hundred feet south of the main vein.

Porcupine.—At the McIntyre the No. 7 vein has been intersected by a cross-cut driven at the 1375-ft. level, which has passed through 20 ft. of \$30 ore.—As an indication of the greatly increased efficiency of labor it is stated that the Hollinger Consolidated is now mining and milling about 2½ tons of ore daily for each man on the payroll, as compared to 1½ tons when efficiency was at its lowest.—The Dome Mines is making further experiments with cyanide, and is at present using the low-grade product of the American Cyanamid Co., of Niagara Falls, in place of the high-grade article imported from Scotland.

Obituary

Albert L. Waters died on May 29 at Chun Ping, in China, where he was in charge of a lead-mining enterprise controlled by Chas. E. Richardson & Co., Ltd., of Swatow.

Warren B. Shackelford, one of the most widely known mining operators of the Joplin district, died recently at St. Luke's Hospital in Chicago following an operation. He went to Webb City during the boom of 1898-'99, where he became associated with the late Charles Read in the Bunker Hill mine at Oronogo. Later he became interested in the Snowbird mine at Carthage, and still later was made manager of the Good properties north of Webb City. He was associated with the S. Y. Ramage lead and zinc mines, north of Carterville, serving as general manager for that company. In 1915 he became general manager for three mining firms, Admiralty Zinc Co., Queen Astor Mining Co., and the Sinden Zinc Co., all of which are situated in the Oklahoma field. He was the first man in the district to use water drills to lessen the dust and improve working conditions underground.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

R. W. French is here.

Deane P. Mitchell is in Spain.

J. L. Bruce has returned from Denver to Butte.

J. Power Hutchins is residing in Madrid, Spain.

R. L. Chase is examining mines near Lake City, Colorado.

J. R. Finlay, of New York, is residing at Redlands, California.

G. F. Carr, of Long Beach, California, has moved to Tonopah, Nevada.

L. Vaughan has opened an office at Kroh, in upper Perak, Malay States.

Wilbur H. Grant has returned to San Francisco from Zacatecas, Mexico.

John Graves, Jr., mining engineer of Salt Lake City, is at Kansas City, Missouri.

Douglas Clark has moved from Iquique, Chile, to Stanford University, California.

Edward McDonald has returned to Berkeley, California, from Durango, Mexico.

Douglas Lay has been appointed manager of the Le Roi No. 2, at Rossland, B. C.

J. W. Finch visited the Rand and the Congo on his return from China to New York.

Herbert Laycock has returned to San Juancito, Honduras, from Berkeley, California.

F. G. Cottrell and **Van. H. Manning** are in Europe, engaged in scientific investigations.

C. W. Purington expects to be in Boston shortly, and later will come to San Francisco.

Walter G. Perkins has returned to his former London address at 62 London Wall, E.C.

Charles D. Kaeding has gone to Nevada where he will visit the Simon and Candelaria mines.

Reusslaer Toll is superintending the Blue Mountain gold mine, in Kern county, California.

G. C. Martin, of the U. S. Geological Survey, is studying Yukon and Koyukuk river-basins.

G. W. Schilling has returned to California from Seward, Alaska, and is now at Hollywood.

Courtenay De Kalb has been at Houston, Texas, and is now inspecting mines in central Georgia.

C. E. Challin, New York representative of the General Engineering Co., left for Bolivia on July 13.

Vernon S. Rood, general manager for the Utah Apex Mining Co., at Bingham, is on a trip to the Yellowstone Park.

Sealey W. Mudd and his son, **Harvey S. Mudd**, have moved their offices to 1203 Pacific Mutual Life building, Los Angeles.

K. Tawara, Professor in the College of Engineering, Metallurgical Department, of the Imperial University at Tokyo, is at the Fairmont hotel.

J. M. Callow, president and general manager of the General Engineering Co., has returned to Salt Lake City after spending six weeks in New York.

R. C. Gemmell spent several days in San Francisco recently. **R. G. Lucas**, attorney for the Utah Copper Co. at Salt Lake City, accompanied Mr. Gemmell.

P. G. Beckett, general manager for the Phelps Dodge Corporation, at Bisbee, Arizona, is in New York. He visited the Yellowstone Park and Salt Lake City on his way.

O. B. Hofstrand, metallurgical engineer, has returned to Salt Lake City after having completed an extensive investigation of the Tintic Milling Co.'s plant and process at Silver City, Utah.

THE METAL MARKET

METAL PRICES

San Francisco, July 19

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	8
Copper, electrolytic, cents per pound.....	13 60—13 50
Lead, pig, cents per pound.....	4 65—5 65
Platinum, pure, per ounce.....	\$70
Platinum, 10% iridium, per ounce.....	\$88
Quicksilver, per flask of 75 lb.....	\$47.50
Spelter, cents per pound.....	6 50
Zinc-dust, cents per pound.....	9

EASTERN METAL MARKET

(By wire from New York)

July 18.—Copper is inactive and slightly weak. Lead is easier but prices are unchanged. Zinc is quiet and easier.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

WE MUST WORK OUT OUR OWN SALVATION

Instead of waiting for some mysterious set of forces to restore good times, the people of the United States have settled down to the grim and sober business of working out their own salvation, writes Archer Wall Douglas, chairman of the Committee on Statistics and Standards of the Chamber of Commerce of the United States in his monthly review of business conditions in the August number of *The Nation's Business*.

While the return to better times is certain to be slow, he says there can be no doubt as to the final recovery. The story of the present business depression," says Mr. Douglas, "is very similar to other depressions which have occurred during the past half century. The beginning of the end of speculation and over-expansion came with restriction of credit that put a sudden crimp in the volume of business and started prices downward on their long journey of decline. Then followed the slowing down in industry, the miasma of much unemployment, and all the attendant evils of hard times. After the first shock, there were a flood of forecasts of an early return to former conditions and the passing of those ills which afflicted the country. Invariably the prophecies came to grief.

"One of the earmarks of past depressions was the fantastic schemes advanced to prevent the return of such eras. These schemes included the stabilization of prices and doing something to the currency so that its purchasing power would always be the same. And there are those among us who take these theories seriously today just as our forebears did in their day. We have at least one consolation in this generation, that out of the welter of past misfortunes we have learned the lesson of sound financial system as embodied in the Federal Reserve Bank."

ADVICE FOR THE INVESTOR

Two of the most effective arguments of the get-rich-quick promoter have been outlined in this column, says a writer in the *New York Evening Post*. The first is the one which impresses the prospective victim with the necessity for immediate action and makes many small savers bind themselves first and investigate afterward. The second consists of a promise of excessive dividends and the apparent honoring of that promise by payments of capital, part of the money paid in by the second batch of victims furnishing dividends for the first batch, and so on, until the law steps in and cuts the chain. The third argument in the order of effectiveness is one used on prospective buyers who do not fall on the first attack. It sets up shining examples of how money invested in the original stock of a corporation now at the top of the ladder, has multiplied from 10 to 100 times. If it is an oil stock that is being offered, the Standard Oil Co. of New Jersey is set up as an example of what has happened and what is likely to happen again. If it is a company which the promoters intend to have manufacture some specialty, the tremendous increase in the value of stocks like Eastman Kodak, Gillette Safety Razor, or Welsbach Mantle is used as bait. A new finance corporation usually points to some top-notch corporation which has realized wonderful success through years of sound management. To the unwary this in general is a powerful argument. An investor possessing even an ordinary sense of conservatism will be likely to inquire whether there is anything in common between the untired beginner and the seasoned veteran other than a common business.

MONEY AND EXCHANGE

Foreign quotations on July 19 are as follows:	
Sterling, dollars, Cable	3 59 1/2
" Demand	3 60 1/2
Francs, cents, Cable	7 85
" Demand	7 87
Lire, cents, Cable	4 58
" Demand	1 35

Eastern Metal Market

New York, July 13.

There have been no important changes in the prices of non-ferrous metals during the week.

Buying of copper continues light and prices continue about the same, with fewer sellers willing to quote below 13 cents.

With the exception of one day, when 300 to 400 tons of tin was sold, there has been no activity during the week.

Lead prices are firm despite the small demand.

Improvement in the zinc market awaits betterment in the brass and galvanized-sheet industries.

IRON AND STEEL

Less rather than more buying has followed the formal posting of new steel price-lists last week, and steel-works operations have not improved, says 'The Iron Age'. Buyers do not question that prices are generally below cost, but they need little steel and await the effect of adjustments in labor and freight-rates.

Further wage-reductions by independent steel companies will go into effect July 16. The rate for common labor is reduced from 37 to 30c. per hour, making the total reduction from the peak about 35%. The Steel Corporation, by abolishing the eight-hour basic day, comes to 37c. per hour for common labor. There are predictions of a 25-cent rate before the downward movement is stopped, as against 19c. before the War. In one Eastern mill town as low as 20c. is now being paid.

The independent sheet and tin-plate mills made a settlement at Columbus, Ohio, on July 9, with the union workers which means a 10% lower labor cost. The Western bar-iron scale is yet to be fixed. Two independent sheet-makers who signed the scale last year are expected to operate on the open-shop plan in the future.

While offers of Belgian and German steel in the United States at low prices are still reported, sales do not result, all buying being at so low an ebb. In Canada likewise offers of Continental steel have been ignored, though at \$10 per ton below American prices.

COPPER

Producers of copper continue to maintain a fairly firm position notwithstanding the light demand. It is probable that the number of sellers who are willing to shade 13c. is narrowing. The leading producers are adhering to this price and are turning away inquiries from buyers who are hunting for the bargain prices. Smaller producers, who are taking the little business that is offered, quote 12.62½c. for prompt shipment and 12.75c. for July. Buyers are bidding 12.50c. for early shipment, but apparently without complete success, it being difficult to shade 12.62½c. Export demand has slumped slightly, the British exchange situation having affected purchases from that origin, while German buyers for the moment seem to have their wants supplied. Germany has been a consistent buyer in lots usually of 100 to 200 tons for some months.

TIN

Except for slight activity on Monday, the market has been quiet throughout the week. On that day 300 to 400 tons was sold, mostly for shipment from the Straits Settlements from June to September. Prices on these transactions ranged from 28 to 28.25c. per pound. Some of the tonnage was for consumers and the remainder was bought by dealers. Otherwise, the market has been featureless. The tin-plate industry continues dull and until there is an improvement there the tin market is likely to continue weak and dull. Prices have softened slightly during the week both here and

in London. Practically the only transactions are in Straits tin. Banca is little heard of, and apparently is finding its way to the Continent. No. 1 Chinese tin, 99%, for shipment from England is offered at around 27.25c. per pound.

LEAD

Lead has been a little firmer than a week ago, 4.35c., St. Louis, having ruled during the last week as compared with a previous price of 4.30c. At 4.35c., St. Louis, and 4.40c., New York, the leading interest has the market pretty much to itself as none of the independent producers is willing to sell at these figures; they are asking 4.62½c. and will sell only small quantities even at this price. Demand is reported as improving, the storage-battery companies being in the market for a fair tonnage.

ZINC

The slight upward trend in price noted last week was maintained until the beginning of this week, when the market turned soft again, the metal being obtainable at 4.30c., St. Louis, or 4.80c., New York, as compared with 4.35c. and 4.85c., which ruled last week and a part of the week before. Business continues dull, and it is not expected that there will be any sound improvement until the sheet-mills experience a better demand for galvanized sheets. The brass industry, a large user normally, also continues dull.

ANTIMONY

The market is slightly easier today, quotations of 4.65c. having been made on spot carload lots, f.o.b. New York, duty paid. Buying is at low ebb.

ALUMINUM

The leading producer continues its quotation of 28c. for virgin pure metal, 98 to 99%, f.o.b. producer's plant, while the same grade of foreign origin is available at 22.50 to 23c., New York.

ORES

The prospect of a tariff on tungsten ore has stiffened prices somewhat. There was an inquiry a few days ago for 300 tons, on which buyers expected quotations of \$3 to \$3.25 per unit, but some sellers are holding for as much as \$4.50. In the absence of business the market price is not well defined and whether purchases could be made under \$4.50 has not been determined.

Ferro-tungsten is quoted at 48 to 50c. per pound of contained tungsten in lump form, guaranteed as to quality, but some grades can be purchased as low as 40 cents.

Molybdenum: A nominal quotation is 50c. per pound of MoS₂ in regular concentrate, usually 85%, but some sellers are holding for 60 to 65c. for this grade.

Manganese Ore: With stocks of ferro-manganese exceeding requirements and ferro-manganese furnaces almost all out of blast, there is no demand for manganese ore, prices of which are slightly weaker. High-grade foreign ore is now obtainable at 22c. per unit. The impression prevails in the trade that the proposed duty of 1c. per unit will not stand in that form when the bill is finally passed.

Manganese-Iron Alloys: The demand for ferro-manganese is confined to an occasional carload lot, quotations from selling agents for domestic producers ranging from \$70 to \$75 per ton, delivered east of the Mississippi river. British selling agents nominally quote \$75, Atlantic seaboard, but would doubtless meet competition if real business were offered to them. Spliegelisen is likewise weak and featureless. Quotations varying from \$26 to \$30 are reported, and there is no doubt that the lower figure could be done if any business of importance were offered.

T. A. RICKARD, . . . Editor

CONSIDERABLE interest was shown a few months ago in a new flotation process with which the name of Luckenbach was associated. In the department allotted to 'Industrial Progress', which is set aside for interesting information contributed by manufacturers and their agents, we print a statement sent to us by Mr. Roger Luckenbach himself. Whether a pine-pitch solution evades existing patents is a matter of opinion, legal more than metallurgical.

HOLDERS of U. S. Steel Corporation common stock at the closing of the books for the June dividend numbered 105,310. This was the largest on record and showed a gain of 934 since March. The owners of preferred stock in the same enterprise numbered 81,614 at the end of May, so that, exclusive of duplications, the U. S. Steel Corporation has about 165,000 shareholders. This is an interesting example of the way in which a wide public interest is created for the stock of an industrial enterprise, and it suggests a recruiting of capitalists from the ranks of labor.

THE visit of the U. S. battleship 'Tennessee' to San Francisco recently served to draw attention to the success that has attended the extension of the application of the electric motor; for this ship was the first battleship to be designed specifically for steam-electric propulsion, being equipped with Westinghouse machinery for this purpose. The turbo-generators deliver a 3400-volt current, each unit, with exciter, condensers, and other auxiliary apparatus, occupying a water-tight compartment. The four propeller-motors are each of 8375 horse-power, and are also contained in water-tight compartments. The 'Tennessee' is a magnificent craft, 624 feet long, and of 33,000 tons displacement. The extraordinary steadiness of the vessel is indicated by the fact that a pool-table is provided for the use of the crew. The combination of oil-burning boilers and electrically operated machinery is an evidence of progress in marine engineering.

SPEAKING of the papers published by the Institute and the needless expansion of its activities in that direction, we instance several papers, in pamphlet form, received recently. One deals with 'Transition Phenomena in Amalgams'. This refers to dental amalgams and should have appeared in the transaction of a dentist's

society. It has no place in a mining and metallurgical publication. 'The Geology of the Namma Coal Field, Burma', is unlikely to interest many of our members; the printing of it is merely a courtesy to the author. 'Underground Mine Development, Its Definition and Valuation' is a note, occupying seven pages, that might be published suitably in the technical press, but is unsuitable for the Transactions. Even Mr. H. V. Winchell's timely and interesting sketch of geologic conditions at El Oro and Pachuca is more suitable for the technical press, where it might elicit useful discussion, than in a reference library such as the bound volumes of Transactions.

RELIABLE statistics have been lacking, since the beginning of the War, of the production, consumption, and commercial movements of many of the non-ferrous metals. This has now been remedied by the issuance of a year-book by the American Bureau of Metal Statistics, of which Mr. W. R. Ingalls is Director. It is explained that during the four years of the War, as well as during the year or so that followed, statistical records were neglected, with the result that serious gaps were noticeable in statements that attempted to show the world's production of copper, lead, and zinc. The Bureau has succeeded in obtaining most of the information that was lacking, thus permitting a relatively complete series of tables to be issued. State departments that issue statistics of national importance are usually prompt, but few governments give the necessary information; our own, we are told, was unable to furnish essential data; figures obtained from this source were sometimes in serious error. The publication of a year-book of such statistics will draw attention to the need for accuracy.

CHARLES G. DAWES, Federal Director of the Budget, has proved himself to be unusually versatile, resourceful, and aggressive, but we suspect that the task before him now is the hardest he has ever undertaken. Three weeks after assuming office he reported a possible gross reduction of some \$115,000,000 in the expenses of running the Governmental departments during the present year. However, it is one thing to point out where savings can and ought to be made, as Mr. Dawes seems to have done, and quite a different thing actually to detach from the Government payroll enough employees to account for a saving of \$115,000,-

000 or any considerable part of that sum. For every score (or thereabouts) of Civil Service employees there must be a Federal appointee; and for every appointee there must be a Senator or a Representative, who, for one of divers, but none the less potent, reasons, is vitally interested in perpetuating the status of such appointee as a servant of Uncle Sam. Moreover, it is probable that, although the heads of bureaus may be heartily in favor of economy and retrenchment as matters of principle, each might consider the suggestion of a curtailment of his essential activities as preposterous. We are inclined to prefer the balance-sheet at the end of the year, instead of the budget at the beginning of it, as an index to the economical conduct of our Government, particularly in view of the prevailing custom of squaring accounts by means of the Deficiency Appropriation Bill. Nevertheless public sentiment is unusually strong in favor of economy, and Mr. Dawes is not afraid of offending, or averse from fighting, strong 'influences'; so we may be pleasantly surprised. We hope so.

AT LAST the worm has turned! It is a long worm that has no turning. Our contemporary in New York, declining at first to join us in a frank criticism of the Institute's exuberance as a publisher, has now endorsed our criticism, and in a most effective manner. We demur, however, to two items: the comparison of the Institute magazine with 'The Mining Magazine', for in one regard if not in several, the publication in London deserves respect, namely, for its précis of technology, which is a credit to technical journalism. We demur to "there is some data"; if the editor in New York had profited by the lessons given in 'Technical Writing' instead of permitting the publication of a mean review of that little book, such a blunder would not have appeared on the editorial page of our contemporary. However, that is by the way. We are amused to learn that the 'Engineering and Mining Journal' offered to act as an organ of publicity for the Institute, that is, to combine with the Institute in publishing much of the piffle that appears now in the Institute magazine. One practical suggestion, however, is offered: it is that the Institute charge \$1.50 per annum for its magazine to those who wish to receive it. That is a good idea; for then the Institute would not be debited with the cost of those copies of the magazine—about two-thirds, we venture to surmise—that go into the waste-basket, and its unfair competition with the technical press would be abated, although not entirely stopped.

THE prospectus of the Santa Monica-Bakersfield Oil Company has been sent to us, by a reader, because it contains sundry oddities. For instance, it asserts that 62% of oil enterprises succeed, whereas only 50% of the drug stores and 33% of the groceries are successful. What is the criterion of success in the oil business? Is it the winning of oil at a profit large enough to amortize the capital investment, plus, say, 15% on the principal, or is it the persuading of the public to sub-

scribe for stock the face value of which is never redeemed? In the case of the company mentioned, the seeking of oil is supplementary to the working of sundry claims containing veins of gold and silver, principally silver, concerning which two interesting statements are made: the first is that "silver is now stabilized in value at \$1 per ounce", and the second that "silver ore increases in value by depth". As to the first statement, we agree that the price for silver of domestic production is safe at \$1 for about three years, but that does not warrant the unqualified assertion just quoted. As to the second, that is a nursery tale. *Credat Judaeus Apella*. In Orange county, where the company's oil-land is situated, "there exists a vast sea of oil!" The mark of exclamation is not ours; it appears in the prospectus. Another "geological indication" is based upon the supposed fact that "the Miocene, Pliocene, and Eocene strata are the acknowledged oil-bearers"; therefore, of course, if you have on your land any strata belonging to these three sub-divisions of geologic time you are sure of finding oil in them. The prospectus appeals to "the thrifty man or woman" and asks him or her to become "a business colleague" with the gentlemen who have this affair in hand. We believe they are honest, but ignorant.

A RECENT yarn in 'The San Francisco Examiner' is headed thus: "Sinaloa Placer Gold Deposits so Rich as to Tax Human Credulity". The article says that Mr. Ralph L. Van der Naillen of Oakland has returned from Mexico with a collection of gold nuggets, ranging from half an ounce to four pounds in weight, these being typical of what can be found readily along the Yaqui, Mayo, Puerta, and Sinaloa rivers in northern Mexico, on thousands of square miles of placer ground for which he, Mr. Van der Naillen, has secured concessions from the Mexican government and on which he "contented himself with saying, gold in paying quantities existed everywhere". "Everywhere" is comprehensive. So is this: "Coarser gold, too, he found in abundance on the Puerta river, where one of the vastest deposits of pay gravel exists that heretofore has been found anywhere on earth". He asserts that he found "wonderful deposits of ancient gravels such as early explorers saw in Nevada and Butte counties, California, but extending over a far greater area, and as far as sinking shafts to bedrock, drilling, panning, and other exploratory work disclosed, these gravels are even richer than the product of those placers which served to build up San Francisco from a slumbering Mexican outpost to the metropolis of the Pacific". How much of this ebullition may be attributed to the imagination of the reporter who interviewed Mr. Van der Naillen and how much to that gentleman himself we do not know. If the interview had taken place in Mexico one might suspect the vivifying effect of the well known distillate from the plant known as the agave, but this possibility should be precluded by the fact that the meeting took place within the scope of the 18th Amendment. Two features of Mr. Van der Naillen's adventures arouse particular curiosity. We learn that

"even the adobe walls of the hovels in which the Indian population dwell, when pulverized with a hammer and washed, disclose a long pay-streak in the pan". Why were the huts demolished when clay similar to that from which the bricks were made must have been abundant? But the most interesting part of the account from a technical standpoint has to do with the examination of the craws of a number of chickens provided for dinner. It seems that Mr. Van der Naillen's cook was not to be outdone by the others in the party in his earnestness to find gold. He was rewarded on one occasion by finding, in the gizzards of a number of fowls, quartz sand and coarse flakes of gold "readily visible to the naked eye", and in quantity sufficient to fill a "small homeopathic vial about one-quarter full". Now if the sand in the yard where the chickens ran had been so rich it doubtless would have attracted the keen attention of the gold-seekers; so that it is reasonable to assume that the fowls had in some manner effected an excellent concentration. The question arises whether these particular birds were endowed with a genius for selecting only goldbearing quartz in the course of their daily scratching, or whether their gizzards had some strange preferential affinity for the valuable particles which they retained while the valueless quartz was being discarded as 'tailing'. Fortunately Mr. Van der Naillen declined to furnish any figures on the probable value of the gold in the ground comprising his concession, for, as the interviewer remarks, "such a calculation would stagger human reason". How very thoughtful! and so like the 'Examiner' and its scribblers.

PREVENTION is better than cure: by isolating the unfit, the frequency of industrial disease and poisoning would be reduced, and some occupations now regarded as dangerous might be rendered safe. We drew attention to this recently in discussing miner's phthisis, and the need for the enforcement of a regulation that tuberculous men should not be permitted to work underground. This is also the opinion of Sir Kenneth Goadby, as expressed in a paper read recently before the Royal Society of Arts. Modern research, we are told, has shown that the white corpuscles of the blood are the chief destroyers of living germs and poisons, and that diminished resistance to poisons is accompanied by a decrease in their number. In his researches on the composition of the blood, Sir Kenneth found that, in all chronic infections, an alteration in the proportion of white cells to red cells may be detected, this change occurring before the outward signs of ill health are apparent; diminution in the number of white-blood cells is accompanied by diminished resistance to such poisons as lead and mercury, making persons in such a condition particularly susceptible. He recommends therefore that tests (blood pressure and blood counts) be made on persons entering such occupations; and he urges that trade-unions encourage the formation of special health committees, not for providing medicine for the sick, but for conserving their capital, health.

Volatilization of Metals

In this issue we publish an article, by Mr. Thomas Varley, the superintendent of the Intermountain experiment station of the Bureau of Mines, and Mr. C. C. Stevenson, a metallurgical research Fellow at the University of Utah, on the volatilization of metals in ore. This paper gives an account of the work that has been done to date, covering the volatilization phase of a process that may become of commercial importance. There seems to have been no difficulty in separating the metal or metals from the gangue; the trouble has been to obtain a product without incurring prohibitive losses between volatilization and realization.

The earliest investigator in this most interesting field of metallurgical research was Mr. Stuart Croasdale, who published, in 1903, the results of tests at Denver on complex silver and gold ores, particularly in connection with those that contained copper. This particular problem, by the way, is one that is engaging the attention of a number of mining companies. There is, for instance, an immense deposit of comparatively low-grade silver ore in the Cerro de Paseo mine, in Peru; copper is also present in an undesirable quantity; there is too little in the ore to justify smelting and too much to predict a favorable result from ordinary cyanidation. Research and experimentation are being carried out on the property, the work being in the capable hands of Mr. Rudolf Gahl, whose conclusions will be of considerable economic significance to the Cerro de Paseo company. Mr. Croasdale's original tests were made by placing the mixture of crushed ore and salt in a clay roasting-dish, and by heating it in a muffle. It was found that nearly 98% of the precious metal could be volatilized in an hour. The best results were obtained when the amount of salt added was equivalent to 4% of the sulphur in the ore, which was ground, according to requirements, to pass a screen that varied from 20 to 60 mesh. The temperature was maintained at about 1000° C. For practical operation a cylindrical revolving furnace was recommended. It was found that volatilization was efficient only with excess of air, and only when the roasting was accompanied by constant rabbling. For the collection of the fume, Mr. Croasdale tried cotton and woolen bags, scrubbing-towers, and burlap filters, aided by pressure or suction. Great difficulty was experienced in the collection of the copper chloride, the failure in this respect leading to a lack of confidence in the possibilities of the process. In 1913, however, Mr. Ben Howe reported the successful volatilization of gold from a complex ore in Western Australia; during the same year the writer of these notes duplicated the results on a small scale, but on an ore of almost identical character in Africa. Mr. Howe's plant, which showed an appreciation of most of the principal recommendations in Mr. Croasdale's earlier work, was complete, and gave excellent results, although the scope of the operations was restricted by shortage of funds. A rotary brick-lined furnace was used, the ore being heated by means of an oil-burner. The charge, containing 5% of salt, was fed

into the volatilizer by means of a screw-conveyor; the fume passed into a dust-chamber, and then through traps of different types, water being used to assist in the removal of the metal from the gas. In these tests there was no question about the successful volatilization of the gold; but, so far as actual saving was concerned, the process was viewed with a considerable amount of scepticism. Subsequent developments have proved that this was justified.

Increased attention was directed to the process in 1913 by the successful experimental work of Dr. F. G. Cottrell in connection with the electrical precipitation of dust and fume. In the utilization of Dr. Cottrell's discovery would seem to lie the hope of the commercial success of the volatilization process. Mr. Croasdale's work, however, not only opened a promising avenue for industrial research, but indicated a greater need for care in the use of salt during the various stages of gold-ore treatment. The ease with which gold could be 'lost' was not generally recognized; it was always looked upon as a particularly stable element. Discrepancies and variations between the results of different assayers and between theoretical estimates and actual yields were attributed to many causes, but volatilization was seldom considered as worthy of consideration. Following an appreciation of the effect of the addition of salt before roasting, it was considered in many quarters a wise precaution to omit the use of a salt cover, or the admixture of salt with the charge, in assaying precious-metal ores.

The ultimate efficiency in the treatment of gold ores is usually judged by the amount of metal that is left in the residue. At one large plant at Kalgoorlie, for example, a concentrate was roasted, prior to fine grinding and cyanide treatment; and it was found that the previous admixture of salt led to a poorer residue. The indicated extraction without the use of salt was from 80 to 90%; with the salt it rose to 97%, as shown by loss in residue. Although the amount of salt that was added (four pounds per ton) was small, it is not unlikely that some volatilization took place during roasting, and this tended to swell the 'unaccountable' loss that often accompanied cyanidation in the earlier days of the process.

In reviewing the subject we are struck with the apathy that followed the pioneer work of Mr. Croasdale in this interesting branch of metallurgy. The best proof of the soundness of his early investigations is that most of his suggestions and conclusions, all of which were of fundamental importance, have been favored by adoption at the hands of later sponsors. The rotary type of furnace has been found to give the best results; the benefit of a scheme of treatment that ensures rapid oxidation is also appreciated. The article on another page will serve to draw further attention to the subject. The facilities at the Bureau of Mines experiment station, for the carrying out of work on the realization as well as on the volatilization stage of the process, are such that important data should be forthcoming from the special investigators who have been entrusted with the experimentation. The treatment of refractory ores presents insistent problems;

doubtless, in this work of the Bureau, knowledge of immense scientific and economic value will become available for adaptation in other phases of metallurgical work.

Conditions in Germany

First-hand information is always valuable. For this reason the following impressions of conditions in Germany today will, we feel, be read with interest; they are those of Mr. H. E. Skougor, whose professional connection with Chuquicamata will be recalled, and who returned recently from a trip to Europe in company with Mr. E. P. Mathewson. We learn that there is little difference between the Germany of today and the Germany of 1913. Its cities are clean and orderly. The Germans are working hard and conscientiously, which, as Mr. Skougor remarks, is not the case in many other countries. The restraints and the economies of wartime are still in evidence. White bread is almost unobtainable, even in the best hotels; sugar and butter are classed as luxuries, and little of either is seen; the Germans are buying no cotton, with the result that paper table-napkins and paper table-cloths are being used exclusively; only one out of about ten lamps on the streets are lit at night. Such, he says, are a few of Germany's efforts to economize; the period of readjustment will be all the shorter, far shorter than is generally supposed. Furthermore, a stable Russia is considered as one of the essentials to success in Germany, and better results may be achieved through pressure on the part of Germany than through the diplomacy of the Allies. Germany has procrastinated about the payment of her debts, but that, in Mr. Skougor's opinion, is a national characteristic. The delay has been due in part to the fact that Germany may not have selected the best talent for the presentation of her case, also because of the aloofness of the United States and the lack of unity among the Allies. It is maintained that a definite stand must be taken and adhered to. Germany is unable to withstand aggressive action; the Germans want to know how long Poland will be allowed to disturb their frontiers, and also if they are to be permitted to retain their holdings in Silesia and in the Ruhr district. It is suggested that when Germany knows the conditions she has to face in the immediate future she will be able to organize her industries on such a basis that the debts will be paid. Can the United States, having attained financial sovereignty, afford to maintain her old-time policy of isolation? Germany, remarks Mr. Skougor, is today pinning her hopes on the Premier of Great Britain, Mr. Lloyd George, who is viewed in Germany as being far-sighted and broad-minded to a degree that sets him above contemporary statesmen. Our informant deplores the fact that there are so many empty vessels in the harbors of the world, that factories are inactive or working half-time, and that men are idle. Unity of action is needed, together with the application of the laws of economics, influenced with as little as possible of passion and temperamental bias.

DISCUSSION

Standardizing Steel for Mining and Milling

The Editor:

Sir—Science is classified knowledge. In order to classify the existing knowledge of any subject, a detailed and exact study must be made. The laws that govern cause and effect must be interpreted, and the varying effects of the many factors entering into combinations must be co-ordinated and classified.

The wide variation in mining and milling processes, dependent on the character of rocks and ores handled, makes it difficult to standardize materials that are made of steel, so that they will be adaptable to all equipment and to all conditions. In reviewing the attempts and efforts to establish standards I note a lack of co-operation between the mining men producing the ores, between the millmen treating the ores, and the steel-men supplying the materials for the equipment used. The mining engineer has the problem of digging the ore; the mill-metallurgist and engineer, the problem of crushing the ore and of recovering the valuable minerals and metals; and the steel metallurgist, the problem of supplying material that will most efficiently and adequately accomplish the results sought for by the other two.

Frequent references have been made in the mining journals to the performance of steels used in mining and milling operations. Numerous experiences have been cited of failures under certain conditions, and successes under other conditions. Those conditions have included the kind of rock handled, the type of machine used, the skill of the operator, and often the kind of steel used, and the treatment of it, either by the manufacturer or the user. Experiences have covered all types of machinery, such as stamp-mills, crushers, rolls, balls, liners, dredges, and smelting equipment. Writers have considered failure of material, such as abnormal breakage, premature wear, and non-adaptability. Often a part made of identical material failed with one operator, whereas, with another, success was achieved.

It must be realized, primarily, that the manufacture of materials into a product, and the process using that product, are two opposite phases of the situation. The manufacturer of steel to be used for a machine, or part of a machine, is concerned with the treatment and the performance of his product, in the use for which he sells it. A manufacturer of drill-steel is interested in the treatment and the performance of that steel for rock-drills; a manufacturer of lips for dredge-buckets is concerned with the treatment and utilization of his steel in that product. But the user of drills and drilling ma-

chines is essentially concerned with the drilling of rock, for which he buys drill-steel and drills. And, likewise, the user of bucket-lips is essentially concerned with the digging of earth, rock, and gravel, for which he buys lips. Also the manufacturer of the drill-steel is not informed in detail of the operation and performance of drilling machines and the drilling of rock. And again, the manufacturer of bucket-lips is not generally fully informed as to the details of digging machinery, of the factors and vicissitudes attending such operations. Often, however, special men are put in the field to obtain such information for the manufacturer; it may be stated that the mining engineer is not a steel metallurgist, nor is the steel metallurgist a mining engineer.

The question then arises: how may the deficiency be remedied, so that each may combine the special and classified knowledge of his particular science, for the benefit of the other? Will the mining engineer and mill metallurgist devote his time and study to the problems of steel manufacture, or will the steel metallurgist devote his time to a study of the conditions that exist in the mining and milling processes?

No dogmatic opinion is expressed, but I offer a proposal for the solution of the problem. The steel metallurgist can better go to the mines and mills and study the conditions affecting the use of steel materials, than can the mining engineer and mill-metallurgist go to the steel mills and learn steel making and the treatment of steel. This opinion seems valid for many reasons. The steel metallurgist is essentially a material-supply man. His processes have, for their origin, the utilization of materials—steel and iron. His studies and experience have taught him the results of combinations of iron with carbon, with manganese, with silicon, with nickel, with chromium, with vanadium, and with other steel-improving metals. By subsequent treatments he understands how those properties may be intensified and modified. He appreciates the application of the characteristics of various steels, and the selection of the steel most adaptable to certain conditions is his problem. With his knowledge, the steel metallurgist will be enabled to assist, and to take the initiative in benefiting the material-standards problem in mining and milling.

The steel metallurgist is, primarily, the best man to study the problem. But it must not be inferred that the operator's experience with materials is not of great value. "The proof of the pudding is in the eating", and no benefit would accrue unless the opinion of the operator was taken into consideration. But as the material problem is essentially the manufacturers' burden,

why put it on the mine and mill operator? In many instances the staff on the property studies the problems of steel and its treatment, and gains a superficial knowledge of the subject that is often more harmful than beneficial.

With all respect to the brains and capabilities of the mining engineer, the mill-metallurgist, and the metallurgist of the non-ferrous metals, and in defence of the steel metallurgist, the following remarks are made. In many milling, and smelting operations, steels of the alloy grades are used in large quantity and in many shapes and sizes. Since alloy steels have been used so extensively for mining and milling machinery, the salesmen of the steel companies have been giving a sort of correspondence education-course on steels, their properties, treatment, and use. This is a good move in the right direction, for it familiarizes the buyer with the product of the seller; it also benefits the buyer because of clear co-operation between the steel-maker and the steel-user. But this educational work has often produced different results. Many operators so educated, superficially, succumb to a malady that arises from the fact that "a little knowledge is a dangerous thing"; they soon pass out of the learning class, and themselves become experts (?). Then opinions are expressed, often to the detriment of the manufacturer's product. For frequently one operator's unfavorable report on a steel product is not justifiable, for the user of the product is often more to blame than the manufacturer. On the other hand, it must be admitted that an operator's observations and opinions have saved the steel-maker from much grief.

The steel metallurgist is a specialist, and his knowledge cannot be acquired to the same extent by one who is a specialist in another field. Therefore, why not call in the steel metallurgist, put the problem of material performance up to him, take him to the mines, the mills, and the smelters, and co-operate with him on the ground? This procedure should appear reasonable and logical; it should give results, for it places the work in the proper hands, and utilizes the brains of those who understand the material being considered. Selection of the proper steel for use requires careful study, equal to the manufacture and treatment of it; for the one can only be the complement of the other.

An abstract ('M. & S. P.', March 12, 1921, page 361, *et seq.*) from I. M. M. Bulletin 196, stated that the Mines Selection Committee had reported the tests on 38 drill-steels, and had reached certain conclusions. Conclusion number one said: "There is no practical difference in open-hearth, Swedish-bessemer, electric or crucible-steel, provided they are of the same composition". These conclusions, of course, were obtained on drills, made from the respective steels. I would like to inquire as to the manner in which these steels were treated as drills, to give results that showed "no practical difference" in their performance as drills. Were all the conditions of the tests identical for the four grades of steels tested? A drill to be of any efficient use must be heat-treated to develop properties required in such use. It

would be reasonable to infer that the steel was mishandled, or that the correlation of the results was inaccurate.

A Swedish- or British-bessemer steel, having the same composition as a basic open-hearth steel, will not give the same results in a test specimen. A difference would be a definite advantage or disadvantage. What appears to me as an inconsistency is the fact that no one of the four steels showed any "practical" advantage or difference over another; the Swedish-bessemer and the open-hearth steels showed the same value in drills.

In commenting on the Mines Selection Committee's report, E. A. Wright states: "With regard to these various deductions I am in agreement with the first statement. Provided that steels are of exactly identical composition, there is no valid reason why steel made in the acid open-hearth furnace should not be equally efficient as steel produced in the crucible".

In criticism of this statement, I beg to submit a few valid reasons why Mr. Wright's statement is incorrect.

1. Crucible steel is homogeneous. Its manufacture in small quantity assures this quality.

2. Acid open-hearth and all open-hearth steel is impregnated with occluded gases and oxidized products, which decrease the ductility and the tenacity of the steel.

3. The fatigue-efficiency of crucible-steel is greater than that of acid open-hearth steel, and also the efficiency of the steel for hardening purposes.

4. Homogeneity promotes efficiency, by the uniformity of the crucible product.

5. Tool-steel quality cannot be produced in the acid open-hearth furnace. The commercial size of the open hearth precludes this.

6. The care and selection in crucible melting-stock guarantees a purer and more homogenous product.

These are valid reasons for the higher efficiency of crucible-steels over open-hearth steels, acid and basic. Efficiency, undoubtedly, refers to performance in service; but such performance depends on the treatment in the first stages of manufacture. In actual use and practice, the compared properties of the two steels exhibit superior performance for the crucible product over the open-hearth product.

Mr. Wright then continues: "From the financial point of view, steels made in the open-hearth furnace are rarely if ever as pure as the electric or crucible product, and the latter class of material therefore naturally commands a considerably higher price". Why? Simply because of the purity and consequent uniformity of the crucible product, and the absence of interfering foreign substances, which affect the properties of the steel. Mr. Wright has answered his own question. The less the amount of counter-effectives in steel, the more pronounced is the effect of those elements that are intentionally put there.

In standardizing a material for a certain use, some system must be adopted. No material can give satisfying service and performance unless it be intelligently handled, with a knowledge of its properties and the require-

ments of its uses and applications. For many of the articles written on the subject it would be simple to infer that the purchase of the materials has been conducted with only a superficial and indirect knowledge of the requirements. The treatment of the material, and its adaptability for the use for which it was purchased, have not been in harmony. In many cases, no doubt, the proper material was purchased, but its subsequent treatment was not properly conducted. In this respect the heat-treatment of steels is referred to. In many plants this subject is not given the consideration it deserves, and less knowledge of the subject is exhibited than in any other phase of the materials problem. Standardization must be adopted for the equipment that is needed to treat and handle the material in a proper manner.

The human side of the problem must not be ignored. Why not standardize the men to do the work, also? Why put the millman, the mining engineer, and any of the staff of the mine or the mill on the steel-materials problem? To adapt material and equipment to a job, and do it efficiently and economically, by correlating the many tangible factors of the problem, means to standardize. Then why not properly adapt the problem to the man best qualified to handle it? Every small plant would not require a steel metallurgist, nor could many afford it. Neither does every mine employ a mining engineer; nor every mill, a metallurgical engineer. The work can easily be divided among many mines and mills in a district or territory.

Comment is invited on the solution of the problem, as to how the mine and mill operator can best get the proper materials to carry on his operations. It is not possible nor probable that one specification will cover all uses of the same material. Nor will any one treatment serve to condition the material for all kinds of service and performance. The problem is specific, not general. It must be studied from the standpoint of the existing conditions in any specific instance; where duplication of those conditions exists elsewhere, the problem becomes simplified. Cut-and-try methods are discouraging and wasteful. The problem has certain governing laws, causes, and effects; the classified knowledge of the steel metallurgist's science, combined with the operator's experience, will solve it. The co-operation must be close; the steel metallurgist must study the problem at mine and mill.

The Copper-Selling Drive

The Editor:

Sir—The predicament in which the copper industry found itself at the close of the War, with over-production, compared with normal requirements and an immense surplus on hand, has been the subject of no little discussion, several conferences, and, last but not least, the consummation of a financing corporation of \$40,000,000 to aid Europe in buying cheap copper from the American producer.

Apparently, there is little purchasing activity in the domestic market, although copper is at an abnormally low price, in fact, too low for profitable mining. Several questions arise as we view this state of affairs; for example, why does not the home manufacturer take advantage of the present low price and lay in a stock? Why, with the large number of idle operatives, does the manufacturer not take advantage of the situation and operate on the fabrication of standard articles of copper? (Perhaps these are foolish questions?) Does he lack the capital wherewith to purchase such stock, to operate as suggested? If so, would it not pay him to borrow and take advantage of the present low price? Why does he not borrow? Is it because of the current discount-rates, of banking interest-rates? Are these so nicely adjusted that such an undertaking would be unprofitable? Whatever is the matter, the American manufacturer also seems to need assistance to enable him to purchase some of this cheap copper, and, incidentally, help to 'reduce the surplus'.

What would a graph look like covering the rise and fall of copper prices, and the tonnage shipments made to Europe, in parallel and over the 25-year period prior to the War? It would furnish an interesting study. Off-hand, and on recollection, I venture the statement that such a graph would disclose a contemporaneous decline in copper prices with a rise in foreign shipments. In other words, the American copper producer sells all his cheap copper to Europe, and the high-priced metal to the home consumer.

America, charitably recognizing the situation in Europe and the inability of the manufacturers there to buy, also admitting that it is to America's interest to see Europe on her feet, accommodately sells our cheap copper to Europe, and helps her to buy it, notwithstanding the fact that the European manufacturer seems to be doing very well, thank you, or better than the home manufacturer. The difference between the several past occasions and the present is that now Europe is unable to buy our cheap copper, so we are to help them out. This cheap copper they will manufacture with their cheap labor, and, when the American manufacturer gets so that he can buy some of the high-priced copper (when we have unloaded the surplus on Europe) and begins to manufacture it under American wages, Europe will be ready to unload an abundance of this same cheap copper, in manufactured form, on the American market. Where, then, will the American manufacturer be? Protected by a high tariff, or, shall we, also charitably, absorb this surplus? Where will the American consumer get off?

For the sake of argument, let us assume that the American manufacturer had a \$40,000,000 corporation formed to help him buy up this surplus, that he bought up some of this cheap copper, that he put some of the idle operatives to work, that these operatives, able to buy, indirectly stimulate other industries, that the manufacturer could then dispose of this manufactured cheap copper to American consumers creating a demand for what was formerly a luxury, would he not 'reduce the surplus',

employ now idle labor, favor the American consumer, and, incidentally, be able to compete with the cheaply manufactured foreign article made from cheap American copper?

Charity begins at home. Financing the sale of below-cost copper to Europe and with the other hand throttling the home manufacturer is a short-sighted policy. America has been repeatedly the dupe of the European manufacturers in their copper transactions. In this case, it looks as though the American copper producer is the 'easy mark' of European interests. There is not only the handing over of all our cheap copper, with our own factories idle, but the back-fire of cheaply manufactured articles, made from cheap copper to flood this market just when the home manufacturer is beginning to get on his feet after the long period of depression. That was bad enough in the past, but the present paradox, financing Europe to help her to a gift of cheap copper, is the limit.

Coloring of Glass

The Editor:

Sir—Referring to the inquiry by Francis Drake in your issue of June 11, for the cause of the violet coloration of some glass: I fear, from your light comment, that the success of your recent article on 'hoochite', which went the rounds of the newspapers, causes you to attribute too much importance to the effect of inclusions of 'hoochite'. While this mineral is new, the reactions of its principal constituent have been carefully studied for many years, and it can be said with assurance that it does not combine with glass, and that the range of its adsorption isotherm is so small that not even the odor can be permanently held.

Common bottle-glass is made from sand containing iron. If this is permitted to exist in the 'ous' condition it imparts a marked green color to the glass, whereas in the 'ic' (not 'hie') condition it colors the glass a faint yellow, less vivid and considered less objectionable. It is the practice therefore in the manufacture of such glass to introduce a little manganese as an oxidizing agent, but upon continued exposure to light the excess manganese oxidizes, producing a marked violet or purple color.

The most interesting thing about this phenomenon is that it shows that chemical reactions continue in what appears to be an inert mass. I had a set of Warner lenses on my car which were slightly yellowish green when new. Within four years these became a decided violet. Thorpe's 'Dictionary of Applied Chemistry', under 'Glass', explains the action fully, but as the action takes place in the dry it offers no hope as an indicator.

It is hoped that this will discourage neither editor nor correspondents in their search for a reaction which will indicate the presence of 'hoochite' or its emanations. On account of the severe attack upon its outcrops it is generally necessary to employ indirect methods in prospecting for it, except of course in the large cities, where

its exploitation is in the hands of the police. With the modern prospector, familiar with the methods of detecting radio-activity by means of a photographic plate, we may still hope.

Austinville, Virginia, June 23.

Revision of the Mining Law

The Editor:

Sir—I notice copy of the 'Proposed Revision of the Mining Law' in your issue of the 18th instant. I have not the time to read the "proposal", which I will do later, but as one who has had much to do with prospecting and prospectors during the past 20 years, incidentally spending a good many thousands of dollars in the business, I want to record my emphatic objection to Section 5. It evidently has been drawn by some professor whose mining experience has been gained in the class-room, and not in the field. It may be drawn to assist needy surveyors.

As every one should know, the prospector does not do his work on Market street, where the sections, and survey-corners are easily ascertained, but in remote and usually almost inaccessible regions, where not one man in twenty knows where one established Government corner may be found, to say nothing of those that might be needed for the particular discovery made by the prospector. I have been interested, directly and indirectly, in hundreds of mining locations during the past 20 years, and can say that in not to exceed 5% of them did we know the description by section, and often scarcely by township, and I think with the aid of my Brunton I can 'run down' a corner with average success. Many of the corners have been destroyed by fire and otherwise, where they were set in the first place, and it often takes a very competent surveyor to identify them. It was in recognition of this fact that the wise men, Senator Stewart and others, framed the law as we now have it—to my mind a very good law, and one that the professors should not be permitted to destroy just to save them from the necessity of exposing their partisanship in apex suits.

Lodes do not conform themselves to section corners. The prospector does not want 'forties' or 160-acre tracts, but "300 ft. on each side of said lode line", running on the strike of the lode; and he is looking for pay-ore in place, not for 160-acre tracts that may be valuable for timber purposes; and he does not want to hold large tracts of land for five years without a discovery, as this proposed law would permit.

Metallurgical Methods at Rio Tinto

The Editor:

Sir—I beg to call your attention to a slight typographical error in your issue of July 9. In reference to the heap at Bisbee, it should read "containing 1.3% copper", not 13%. As it is an obvious error, it may not be necessary to publish any correction, still I thought I might call your attention to it.

JOSEPH IRVING.

Jerome, Arizona, July 18.

UPPER CAMP OF THE ENGELS COPPER CO.

Operations of the Engels Copper Mining Company—I

By Arthur B. Parsons

HISTORY. The saying that good mines are not found in places desirable for human habitation, like all other proverbs, is emphasized by exceptions. Among these are the Engels mine and the Superior mine, two miles below it, that together comprise the property of the Engels Copper Mining Co. in the northern part of Plumas county, California. These mines are about 25 miles north of Paxton, a station on the main line of the Western Pacific; they are reached by a branch line known as the Indian Valley railroad. Paxton is named after Elmer E. Paxton, who was responsible for the exploitation of the property on a large scale and is now general manager for the company, whereas the mine itself gets its name from Henry Engels, the father of the brothers now connected with the enterprise, who was the first to discover copper ore in the locality. This was about 40 years ago, before the Western Pacific was built; at that time the nearest railroad point was Reno, 150 miles distant, on the Southern Pacific. The present terminal of the Indian Valley railroad near the Superior mine and the company's 1200-ton mill and flotation plant is called Engels, whereas the post-office a few hundred yards farther up the canyon has been officially designated Engelmine by Uncle Sam. Two names for a town of 500 people seems as superfluous as it is confusing; one of them ought to be dropped. In the interests of efficiency and economy it would seem that the Post-Office Department might gracefully yield, thereby saving a syllable and much ink.

I have digressed somewhat from my declaration that Engels is an agreeable place in which to live. It is situated at an elevation of about 4200 ft. on an eastern spur of the Sierra Nevada; the air is dry and exhilarat-

ing, and, although snow is frequently deep during the winter, the cold is never excessive. The drinking-water is the finest that can be imagined; it comes from a torrential stream, called Lights creek, that runs through the settlement. The mountains are rugged and the sides are covered with pine, fir, and cedar, this district being part of the Plumas National Forest. Incidentally, the company owns its own saw-mill and cuts its own lumber and mine-timbers. Indian valley is broad and unusually fertile, so that the best of farm and dairy products and meat are obtainable in Engels at moderate cost. The fishing is fine, quail abound, and deer hunters during the season seldom leave disappointed. Assuming that this establishes the first part of my statement as to the attractions of Engels, I trust the remainder of the article to satisfy the reader that the mines are good ones.

The history of the enterprise is unusual in that the man whose hard work and perseverance did most to reveal the presence of the orebodies in the early days is one of the important stockholders in the established company. I refer to William Engels, better known as 'Bill', who is said to have spent 25 years on Lights creek in exploring and prospecting the copper outcrops and in proving the ore. The senior Henry Engels owned and operated a copper and brass foundry in San Francisco during the late 'seventies; his raw material came from the Lake Superior region, and cost him 35 to 40 cents per pound. The story is that he first went into the Plumas County 'copper belt' because of his interest in the metal from a manufacturer's standpoint. Later he financed the work of his sons, Bill Engels making the first discovery of real importance at a point about two

miles up a small branch of Lights creek where the Engels mine and Upper Camp are now situated. Development of this vein continued for some years before sufficient work had been done to prove that the property had real merit. The next step was to finance the undertaking. For this purpose the brothers organized the Engels Copper Mining Co. in 1901 and raised capital for the erection of a 100-ton blast-furnace plant in which it was proposed to smelt medium-grade carbonate ores.

The smelter, situated about a mile below the mine, was finished; an aerial bucket-tramway was erected to deliver the ore to it; and everything was in readiness to commence operations. At this juncture the Government forestry officials stepped in and notified the company that the operation of the plant would not be permitted. Just what their reasons were I have not been able to ascertain, but at any rate the smelter was on the forest reserve and the authority was competent to prevent any smelting operations.

In the meantime the Western Pacific railroad had been completed, thereby bringing rail transportation within 26 miles of the district. Developments in the mine had been encouraging, so the company determined to build a concentrator, helping to finance its construction by shipping high-grade ore to the smelters in Utah. This ore was hauled by team and motor-truck to Keddies, the nearest railroad station, with which Engels is connected by a fairly good highway.

It was at this juncture that Mr. Paxton, who had been financially interested in the company for some time, personally undertook the direction of the enterprise. He and his associates, one of whom was F. Klamp, now vice-president of the company, raised sufficient capital to build a mill with an initial capacity of 200 tons per day (this was subsequently increased to 600 tons); to install a hydro-electric power-plant; and to provide other necessary improvements. Since that time Mr. Paxton has been constantly at the head of the administration and to him is due great credit for the financial success of the enterprise.

Just then flotation was attracting serious attention for the first time in this country, and tests made by the Minerals Separation people indicated that good results could be obtained on ore from the Engels mine. Accordingly, it was decided to adopt the process and to install Minerals Separation machines. The plant, one of the first to utilize flotation and the very first to depend on flotation exclusively for concentration, was completed during 1914. It was operated successfully until shortly after the starting of the new plant early in 1918. The company has always been a licensee of Minerals Separation; its royalty rate of 12c. per ton of ore treated is about the average charged to users treating approximately 1000 tons per day. It is neither excessively high nor is it as low as that of the companies that concentrate large tonnages.

Hauling the concentrate to Keddies by truck was expensive; moreover the future growth of the mine seemed to be assured; accordingly surveys were made for a

branch railroad to connect with the Western Pacific. The best route intersected the main line at a point four miles west of Keddies, where a new station was established. This was called Paxton. The construction, financed by the Engels company, which now owns practically all of the stock of the Indian Valley railroad, was rushed during the winter of 1916-1917; the line was completed to Engels in June 1917, although for many months concentrate had been relayed by truck to the completed portion of the road as progress was made. The proceeds from the sale of this concentrate supplied much of the capital needed for construction.

The next step was the construction of a larger and more efficient concentrator. A site was chosen on the steep hillside just south of the portals of the adits through which the Superior mine was worked and two miles below the Engels mine. The firm of Bradley, Bruff & Labarthe, of San Francisco, was engaged to design the plant, the construction of which required the greater part of 1917, being completed early in the following year. During 1915 Edmund Jussen was in charge of operations with John Reinmiller as his assistant. When Mr. Jussen retired, Mr. Reinmiller became superintendent, a position which he retained until the summer of 1919. During the War the enterprise prospered. In addition to paying the following dividends,

1916	\$133,451
1917	295,253
1918	269,978

the company spent \$1,052,622 of profit in improvements to its mining and milling plants, the operating profit from June 1914 to December 31, 1918, being \$1,751,306. This record is still more creditable when it is pointed out that no deferred development account was set up, the cost of all such work being charged directly to operation. However, following the collapse of the copper market in 1919 it became apparent to Mr. Paxton that more efficient and economical operation would be necessary if the enterprise were to weather the dull times ahead.

In June 1919 Robert A. Kinzie, of San Francisco, was retained in the capacity of operating engineer. The plan was that the operating organization should be directly responsible to Mr. Kinzie and that he should be more intimately identified with the affairs of the company than a consulting engineer, while at the same time he would be free to undertake work for other clients. Mr. Kinzie selected W. R. Lindsay as superintendent, and Mr. Lindsay resides on the property. This arrangement has proved highly satisfactory, as the results of operations will indicate.

The company at the present time owns 157 lode claims with an area of 3245 acres; of the total, 23 claims covering 457 acres are patented. It also owns 900 acres of ranch-land acquired primarily for tailing-sites. The following summary of the capital expenditure as of January 1, 1921, is of interest.

Mine development	\$140,216.41
Mine property	972,292.30
General equipment	1,465,060.01
Broken ore in stores	440,337.07
General supplies	267,252.27

Cash and accounts receivable	118,523.97
Indian Valley R. R. stock	392,500.00
U. S. bonds	40,000.00
Concentrates	38,735.08
Advance expenses	41,822.70
Total	\$3,910,745.81

The following paragraph from the annual report of 1920 should be noted in connection with the second item above: "No charge has been made covering depletion of orebodies for the year 1920. The original valuation of \$802,255.57 for the mines, set up when operations were begun in 1914, has never been changed and the depletion heretofore charged has practically exhausted this account. In other words, the book-value of our entire mining property, after deducting the present depletion re-

Ore-Reserve in Tons, December 31, 1920

Engels Mine	
Blocked ore:	
In place	1,075,807
Broken ore in stopes	273,554
Total	1,349,361
Probable ore	350,000
Total blocked and probable ore	1,699,361

Superior Mine	
Blocked ore:	
In place	363,000
Broken ore in stopes	108,020
Total	471,020
Probable ore	100,000
Total blocked and probable ore	571,020
Total	2,271,200

The following data show the cost of production during

SECTION OF THE UPPER OR ENGELS MINE. THE NEW ADIT WILL TAP THE WORKINGS 490 FT. BELOW NO. 7 LEVEL.

serve of \$589,060.84, amounts to only \$213,194.73. In view of the large amount of ore now proved and developed, this account will be re-appraised, and pending such action no further charge to depletion reserve will be made". It is obvious that the 'book value' does not represent actual worth.

The production by years, commencing with 1915, is given as follows:

Year	Ore shipped or milled, tons	Copper in ore or concentrate, lb.
1915	59,714	2,893,133
1916	138,712	4,312,408
1917	157,423	5,940,741
1918	266,636	9,419,957
1919	285,113	8,600,000
1920	239,612	8,571,569

The following statement of ore-reserves, as estimated by Mr. Kinzie on January 1, 1921, is extremely conservative; it does not include any ore indicated by diamond-drilling.

1920. The record is excellent when the general high cost of operation is considered in conjunction with the comparatively low grade of the ore (2.21% copper) and the small tonnage (averaging only 657 tons per day) of the output.

	Total cost	Cost per pound of copper, cents
Concentrate on cars at Engels	\$1,077,837.03	12.57
Freight and smelting charges, \$196,107.62		
Credit—gold and silver..... 145,266.07	351,141.55	4.10
Operating and marketing cost	\$1,428,979.48	16.67
Add depreciation and insurance reserve	111,851.64	1.30
Net cost copper production..	\$1,540,831.12	17.97

A material reduction in the cost per pound has been made since January 1; for May the figure corresponding to 16.67c. in the table was only 13.47c.

GEOLOGY. The country-rock is massive diorite or quartz-diorite comparatively dark and of medium texture. The orebodies are lenses or masses of altered

diorite in which the copperbearing minerals are found in veinlets or as disseminated grains. The gangue includes hornblende, chlorite, sericite, epidote, and calcite. Siderite is prevalent and magnetite is generally distributed in the ore. Some tetrahedrite probably accounts for the presence of several ounces of silver in the concentrate. The principal copper minerals are bornite and chalcopyrite, presumably of contemporaneous origin; chalcocite and covellite, from secondary enrichment; also malachite and chrysocolla. The last two are found only in the oxidized zone near the surface and are not of importance. Pyrite is conspicuous by its absence.

Certain questions as to the genesis of the ore in the Engels mine were the basis of a friendly controversy years ago between W. H. Turner and A. P. Rodgers* on one side and L. C. Graton and D. H. McLaughlin† on the other. Turner and Rodgers contended (a) that the sulphides were deposited during late stages of the magmatic period, and (b) that the chalcocite resulted from the action of ascending hot alkaline waters, thus producing "what may be called ascending (secondary) enrichment". Graton and McLaughlin demurred to both of these conclusions. They contended that, instead of being initial constituents of the dioritic rock, the copperbearing minerals "were introduced after the rock had solidified and had suffered notable dynamic and chemical changes"; also that all of the chalcocite and most of the covellite was accounted for by the normal and generally accepted process of secondary enrichment accomplished by descending surface waters. The importance of this last point is obvious: as pointed out by Graton and McLaughlin, in consequence of this general assumption "operations and plans, whether mining, metallurgical, or financial, are based more or less directly on the expectation that at some depth, commonly not very great, below the surface" deposits of chalcocite ore will be exhausted. If, on the other hand, it can be proved that in certain mines the formation of chalcocite by secondary enrichment has been independent of surface influences, but, instead, "is the result of agencies from deep-seated sources", or, stated otherwise, has resulted from the action of rising or ascending waters, there is need for a decided revision of our ideas concerning this important mineral from which comes so large a part of the world's supply of copper.

Turner and Rodgers entertained their theory for some time before they finally presented the Engels deposit as the best example and as the definite proof; they advanced much plausible detailed mineralogic evidence in support of their view. However, recent disclosures on the lowest levels, of the mines, entirely independent of any inductive reasoning, seem to prove conclusively that Turner and Rodgers were wrong. This evidence is simply the finding in the main orebody of large quantities of bornite with an entire absence of associated chalcocite. This controversy and the apparent conclusion have an interest out of proportion to the importance of these compara-

tively small orebodies for the reason that if 'ascending secondary enrichment' were to be recognized in one deposit, the same phenomenon might reasonably be expected elsewhere.

The principal differences between the orebodies in the Superior mine and those in the Engels are as follows: At the Superior a more clearly defined lode from 12 to 20 ft. thick and with a dip of from 30° to 45° as compared, at the Engels, with an approximately vertical mass, roughly 750 ft. long and from 25 to 125 ft. wide, in which the ore merges irregularly into the country-rock. Chalcocite and magnetite are less in evidence in the Superior ore; the copperbearing minerals are more inclined to appear as filling in small veins or fractures than as scattered grains.

MINING. Operations at the Engels mine are conducted through two adits and a vertical shaft, known as No. 2, sunk near the portal of 'shaft-level' adit. The 6th-level adit is 240 ft. below the shaft-level and enters the hill at a point 1700 ft. from the shaft; at its portal is the rock-breaker plant and the loading terminal of a 10,000-ft. aerial tramway that carries all the ore down the canyon to the mill. The ground around No. 1 shaft and those portions of the old ore-zone entered by adits known as the 1st, 2nd, and 3rd levels are now caved; a large glory-hole marks the locality of the caved workings. This is indicated clearly on the accompanying longitudinal vertical projection, which, however, does not show the portion of the 6th level that leads from the shaft to the portal. Ore is being mined from stopes above both the 4th and the shaft levels, but 50% of the output during 1920 came from the main stope above the 6th level, and this proportion will be largely increased during the present year; also stoping will be commenced on the 7th level.

The present arrangement is to hoist ore from the 7th level through No. 2 shaft to a pocket above the 6th, where it is to be re-loaded for electric haulage to the portal. Within the next two years a new adit, 7000 ft. long, will be driven to tap the orebody at a point 490 ft. below the present 7th level. This plan has been under consideration since 1917, but the high cost of operation, the difficulty of obtaining miners, and other obstacles have delayed the work. The portal of the new adit will be down the canyon near the site of the old smelter, the plan being to continue the mine tracks as a surface electric tramway to deliver the ore directly into the mill-bins, thereby avoiding the use of any aerial tram. Other apparent advantages are the draining of the mine to a level 700 ft. lower than the present adit, thereby doing away with pumping; improved ventilation for the entire mine; and the deep exploration of a large area of ground hitherto prospected on the surface only.

A considerable tonnage of good ore in the upper levels can never be obtained. It appears that much of the caving was permitted deliberately; this was done on the theory that the dilution of 2% ore with a large proportion of material that assayed from 0.2% to 1.0% would still leave a mixture that could be mined and milled profitably. It was the intention to draw the entire caved block from chutes on the shaft-level. Apparently those

*'Economic Geology', Vol. IX, No. 4.

†'Economic Geology', Vol. XII, No. 1; Vol. XIII, No. 2.

who preceded Mr. Kenzie in charge were deceived as to the copper content of the low-grade material and as to the quantity that was to be used as a diluent.

Operations at the Superior mine are carried on through two adits at elevations 200 ft. apart and a vertical three-compartment shaft at the collar of which is erected a steel head-frame 108 ft. high, built by the Mortensen Construction Co., of San Francisco. Five-ton steel skips hoisted through this main shaft dump directly into the coarse-ore bin at the head of the new mill, joining the ore delivered by the aerial tramway from the Engels mine. If this shaft were continued vertically beyond the lower of the present adits the distance to the orebodies on the deeper levels would be excessive; accordingly it is planned to commence an incline from the existing sump

drawn off to make room for the stoping operations to be continued. The machine drills are then set up on top of the broken ore, and the drilling, blasting, and drawing-off of one third the ore broken is repeated. This work is continued until the stope has been carried up to the next higher level and completed. The stope so finished now contains two-thirds of the ore broken during the period of stoping, and one third of the ore broken has been drawn off and milled. As soon as the stope is finished, all of the broken ore it contains can be drawn off and utilized. The advantage of this method of stoping is its cheapness, as all timbering and staging are eliminated, and deep drilling and heavy blasting can be used. Its disadvantage is that two thirds of the ore broken in the stopes is not available for the mills until the stopes are

completed. In the case of the Engels mine, where the vertical distance between the No. 6 and shaft-level is 240 ft., it means that two-thirds of the ore broken in the No. 6 level stopes will not be available for from two to three years from the time of starting the work of stoping. It also means that two-thirds of the cost of mining has to be carried in suspense until such time as the ore becomes available. If the development work in a mine has been properly planned and carried out, there should be at least three working levels. On the upper ones, the stopes will have been completed and the work of drawing the broken ore is under way. On the next lower level the development work should have been completed and

FIG. 2. FINGER-CHUTE USED IN THE ENGELS MINE

into the hill. A diamond-drill hole 800 ft. long from the end of the main or upper tunnel has revealed the presence of promising ground beyond the present face, which is 1000 ft. from the portal.

SHRINKAGE STOPING. The ground is remarkably firm and solid, and the backs hold well without timber. This characteristic, together with the fact that the orebodies are from 25 to 75 ft. thick, with nearly vertical sides, offers ideal conditions for shrinkage stoping, the system that has always been used in mining the larger blocks of ore in the Engels mine. In his first annual report (1919) Mr. Kinzie gives a concise general description of shrinkage stoping that is worthy of reproduction. He says: "By this method, the orebody to be mined is first undercut throughout its entire area, with the exception of that portion reserved for pillars. The ore thus broken is entirely drawn out through chutes connecting through the bottom of the stope with the level. The work of stoping is then carried on by drilling and blasting the ore from the back of the stopes. After the ore is blasted from the solid backs, the broken ore occupies one-third more space, and as a result one-third of the broken ore has to be

stoping started; and on the bottom level the work of driving drifts, cross-cuts, etc., to determine the size and value of the orebodies and preparing for future stopes, should be in progress."

Certain changes made in the method from time to time and the reasons therefor may be of interest. The original method of loading ears was by hand-shoveling from the floor of small chambers off-set from the main drift. This method, of course, was expensive but had the advantage of making unnecessary any considerable pillar above the drift-level. Some timber was saved, but this was not an important consideration in a locality where the trees had only to be cut to supply excellent timber. For the stopes above the 6th level, loading-chutes of 4-in. plank were built; these were fitted with chute-mouths and arc-gates, and four feet above were placed grizzlies of old rail. This formed the floor of a bulldozing-chamber where large rocks were block-holed with 'jackhammers'; the stope funneled into the chamber. The objections to this method were: (a) loading through the arc-gates was slow and (b) a sheet-pillar averaging 35 ft. in height above the floor of the drift was necessarily left. New chutes on the

6th and 7th levels are not provided with bulldozing-chambers; instead, the stoped ore is allowed to fill the entire space behind specially built finger-chutes similar to those used at the Treadwell mine in Alaska. See Fig. 2. Some block-holing will be necessary in the stopes as mining progresses but the scheme will obviate the first difficulties mentioned as applying to the former method, and will permit a saving of 15 to 20 ft. in the height of the sheet-pillar.

Formerly no vertical pillars were left in the stopes, but cribbed manways at intervals of 50 ft. were raised as the stopes advanced to afford access for the miners. In the upper levels where the 'lift' was only about 60 ft., as between the 5th and 3rd, it was possible to keep these manways open until the block had been mined; when the attempt was made to carry out the same plan in mining the ore between the 6th level and the shaft-level the maintenance of cribbed manways in the broken ore was found to be not only impracticable but virtually impossible, and they were necessarily abandoned after a height of 80 ft. was reached. None will be started on the 7th level. Mr. Kinzie also decided to divide the main 6th-level stope, then about 500 ft. long, into four blocks by leaving 20-ft. pillars alternating with stopes 120 ft. long. This can be seen in Fig. 1; the pillars start from the vertical height reached in June 1919.

The 6th-level stopes are not to be completed to the floor of the shaft-level; on the contrary, there is to be left a sheet-pillar, which, including the ground immediately above the level, will be 50 ft. thick. The necessity for leaving this pillar arises from the condition of the upper levels as already described. Were it not for the dilution of barren and low-grade rock it would be desirable to let the caved ore in the upper workings follow down through the lower stopes. Under the circumstances the flow must be stopped somewhere, and the sheet-pillar at the shaft-level is designed to effect this purpose.

The interval between levels considered to be most advantageous is 200 ft., which accordingly is the lift from the 7th to the 6th level. Here the stopes will be started according to the ideal plan. The finger-chutes are to be placed at intervals of from 15 to 25 ft. on opposite sides of the level-drift. Pillars 20 ft. wide will alternate with 120-ft. stopes; in every second pillar will be a permanent manway-raise driven through to the level above. At vertical intervals of 20 to 25 ft. the manway-drift will connect with, and afford communication to, adjacent stopes. At one point, where the orebody is unusually wide, foot-wall and hanging-wall working-drifts will parallel each other for some distance, finally making a junction and continuing as one drift.

One third of the ore broken is drawn as the stope advances, two thirds remaining to be removed subsequently. Approximately 300,000 tons of broken ore will be available in the 6th-level stope, the raising of which is now nearing completion, whereas 150,000 tons will have been removed and milled during the ore-breaking period. Arched backs are carried to minimize the possibility of caving. Holes are drilled horizontally with drills

mounted on vertical columns, with a view to obtaining the maximum efficiency in drilling and breaking. The importance of a clean back from the standpoint of safety should be emphasized; it is a fixed policy of the company to take every reasonable precaution against injury of its employees. Square sets are used occasionally in some of the old stopes on the upper levels but it would not be accurate to say that systematic square-set mining is done.

In the Superior mine, shrinkage methods are not generally suitable on account of the comparative flatness of the walls; the slope is approximately 45°. The orebodies are only from 10 to 20 ft. thick and accordingly they can be mined successfully by overhand breast-stoping. A few stulls are used and occasionally a pillar is left to afford additional support, although the back is exceptionally solid and causes little trouble. Wall-pillars as well as post-pillars can generally be left conveniently in places where the ore is comparatively poor. In one stope foot-wall chutes have been raised from auxiliary drifts on the haulage level, parallel to and 25 to 35 ft. from the main drift, in order to draw the ore, which does not 'run' at the flat angle of the foot-wall. Drifts and long raises in barren rock, however, are expensive and as the stopes become higher steel scrapers are to be used to move the ore into the chutes. These will be operated by a tugger-hoist and light cable so arranged that the hoist can be utilized to pull the scraper back, up the stope.

UNDERGROUND EQUIPMENT. Both storage-battery and trolley locomotives are used underground; the former are employed in gathering ears and the latter for haulage in the main adit on the 6th level. The trolley-locomotives are a 4-ton Baldwin-Westinghouse and a 3-ton General Electric machine each capable of pulling trains of 15 to 20 cars. The storage-battery machines are unable to duplicate the performance of the trolley-locomotives but have the advantage of the flexibility required in the work for which they are used. This division of labor has much to commend it. Side-dumping steel cars of the eradle type have been improved by substituting a solid wooden base bound with wide strap-iron for the original fabricated structural-steel base. The constant bumping of the cars as the trains were pulled or pushed resulted in the cracking of the steel, whereas the solid wood seemed to absorb the shock without injury. All the cars are now supplied with wooden bases made at the mine.

The following is a list of the explosives used: in the stopes, 25% gelatine; for raising and other development work, 40% gelatine with some 60%; Coast Manufacturing Co.'s Bear brand fuse for dry holes and triple-tape fuse, water-proofed at the cap-joint with P. & B. paint, for wet holes; No. 6 caps for plugging and block-holing; No. 8 caps in the stopes; and Ideal delay-action electric exploders, supplied by the California Cap Co., for development work. No firing-box is used for the exploders, the current being taken from the electric-light circuit.

Herules tamping-bags are used; these are made of the same paper as is used to wrap dynamite instead of the flimsy wrapping paper of which they were formerly made. They are easy to fill with clay or tailing; they are

not liable to break, and, according to Mr. Lindsay, the miners are actually using them, with a consequent material saving of powder. Many superintendents have experienced difficulty in getting their miners to use tamping material; I believe that the use of these tough paper containers ought to lessen the difficulty. During 1920 a total of 337,700 lb. of powder was consumed in breaking 327,491 tons of ore, or 1.03 lb. per ton. The cost of powder averaged \$0.20 per pound delivered at Engels, making the cost per ton of ore broken \$0.206. Including waste broken, the consumption of powder was 0.97 lb. per ton of rock. The cost of caps and fuse was \$0.053 per ton of ore.

A variety of rock-drills has been in use, but it has been decided to standardize by discarding all but three types of drill, these being of Ingersoll-Rand manufacture. They are the new '448' drill for all work where bars or columns are employed; 'L40', a self-rotating hammer-drill using hollow steel and water, for raising; and 'jack-hammers' for block-holing. The only 'dry' drills except jackhammers now in use are a few 'CC11' stopers, but these will be scrapped in keeping with the company's policy of making working conditions as safe and healthful as possible. The following data show the results of machine-drilling during the year 1920 in the two mines:

	*Average number machine-shifts			Holes drilled per machine shift	Average depth of hole	†Average number ft drilled per machine-shift	Tons of rock broken per machine-shift		
	Mining	Development	Total				Mining	Development	Total
Engels mine:									
4th level	5.61	2.86	8.47	11.6	5.7	10.2
Shaft level	2.65	1.61	4.26	8.8	10.4	9.4
6th level	21.83	4.62	26.45	31.9	5.2	26.0
7th level and shaft	1.89	1.89	10.3	10.3
Totals and averages	30.09	10.98	41.07	6.1	5.3	32.1	25.0	7.5	10.5
Superior mine:									
1st level	12.42	3.04	15.46	19.8	6.0	16.9
2nd level	1.70	2.07	3.77	12.8	7.3	9.7
Totals and averages	14.12	5.11	19.23	5.8	5.1	29.8	18.9	6.5	15.3

*Including pluggers. †Not including pluggers.

It is interesting to note that, whereas the table shows 31.9 tons broken per machine-shift on the 6th level during 1920, the average for the last five months of the year was 40.8 tons. Increased individual efficiency of the miners and better systematization throughout the mine are assigned by Mr. Lindsay as the reasons for this improvement.

The consumption of drill-steel, including pieces lost and discarded, during 1920 amounted to 65,480 lb., or 0.2 lb. per ton of ore broken. The average price delivered at Engels was \$0.19 per pound, making the cost of steel \$0.038 per ton of ore broken. This was equivalent to a cost of \$0.57 per machine-shift for drill-steel. These figures may seem high, but in making any comparison with results obtained elsewhere the hardness and toughness of the rock at Engels should be taken into account.

SURFACE EQUIPMENT. The main hoist at the Engels shaft was made by the Nordberg Manufacturing Co. It is a double-drum machine actuated by a 150-hp. General Electric alternating-current motor, operating at 2200 volts and a speed of 500 r.p.m. It is connected to the hoist through a flexible coupling and herringbone gears. The clutch and brakes are operated by air. A novel chain-driven ball-governor automatically limits the speed

of hoisting. It may be adjusted for any desired rope-speed; if this be exceeded the brakes are automatically set with a suddenness that is uncomfortable to anyone riding on the cage, an occurrence that a good hoist-engineer avoids carefully. The hoist cannot over-wind. One unusual thing about the hoist is worthy of mention for the reason that it calls attention to a mistake that has been made at more than one mine. The drums of the hoist have been shortened by inserting wooden fillers at the outside end. The purpose is to decrease the horizontal displacement of the ropes from alignment with the sheave-wheels, thereby lessening the wear on the strands caused by rubbing on the rims of the wheels. The mistake was this: When the plant was erected the hoist was placed only about 50 ft. from the collar of the shaft, although there was no good reason why the hoist-house could not have been 150 to 250 ft. farther away, thereby lessening the angle at which the rope approaches the sheave, when at the extreme positions on the drum. This would have added materially to the life of the ropes with consequent economy in operations.

A Lidgerwood hoist, designed to operate by water-wheel at the Harvard mine at Jamestown, California, has been re-built for use at the Superior shaft. It is connected through two Falk herringbone-gears, running in

oil, and an intermediate counter-shaft to a 250-hp. 440-volt General Electric induction motor. A feature of the re-built hoist is the arrangement of the brakes. In addition to hand-brakes on the drums, two post-brakes are provided; of these one is on the motor-shaft, which overhangs the bearing, and the other is on the counter-shaft. This arrangement effectively relieves the transmission machinery of the strain that otherwise would be thrown upon it and makes the operation smooth and readily controlled.

Adjoining the Engels hoist-room is the steel-sharpening shop, equipped throughout with Ingersoll-Rand machines, including a fuel-oil furnace, one No. 5 Leyner sharpener, and a punch for use with hollow steel. One man and a helper sharpen, cool, re-heat, and temper 500 pieces per shift under average conditions. At the Superior mine two No. 4 sharpeners are substituted for the No. 5; otherwise the shops are alike.

The compressor plants, one at each mine, are interesting from the fact that each contains an Imperial Type 10 Ingersoll-Rand machine that originally supplied air for the driving of the McAdoo tubes under the Hudson river. Each compressor has a capacity of 2300 cu. ft. per minute; the cylinders are 28 and 17 in. by 24 in.; and

each is connected to a 400-hp. motor by a 40-in. three-ply Reliance leather belt made by the Chicago Belting Co. The use of these high-priced leather belts, costing in the neighborhood of \$1000 each, is interesting for the reason that it illustrates the ultimate economy of incurring high initial cost if it promises long life, steady operation, and low maintenance. The compressor at the Engels mine at Upper Camp ran 24 hours per day continuously for eight months without being shut-down even temporarily, I am informed. Both Imperial Type 10 compressors are run by Allis-Chalmers synchronous motors. In the Engels plant are a motor-driven 750-ft. Sullivan compressor, Class WJ3, and an old steam-compressor that has been connected to run by motor. This machine was made by the Ingersoll-Rand company and saw service for a short time at the Mare Island Navy Yard; nevertheless it still supplies its rated capacity of 1000 cu. ft. per minute quite satisfactorily. At the Superior plant a small angle-type Sullivan compressor serves as an auxiliary.

As already stated, the ore issues from the Engels mine through the 6th-level adit; electric locomotives pull the mine-cars over the storage-bin of the rock-breaking plant where it passes through in a Blake-type jaw-crusher with a maximum opening of five inches. The run-of-mine product contains a great many chunks that weigh from 100 to 200 lb. so that it is essential that the material be broken before it can be loaded into the buckets of the aerial tram that carries it down to the concentrator. The rock-breaking plant is interesting and efficient; it will be described in a second article, dealing with the milling operations.

The tramway was erected by the Riblet Tramway Co. of Spokane, Washington, during the winter of 1917-1918, when the new mill was built. It is 10,000 ft. long and the loading-station is 700 ft. higher than the top of the mill-bins into which the buckets discharge. The track-cables are of the locked-coil type, the present cable being supplied by the American Steel Products Co.; the cable carrying the loaded buckets is $1\frac{3}{8}$ in. diam., whereas the track for the up-going buckets is $\frac{5}{8}$ in. The running or traction cable now in use is $\frac{5}{8}$ in. diam. Thirty-two towers support the cable and two intermediate tension-stations divide the track-cables into three approximately equal segments. There are 48 buckets, each with a capacity of 1100 lb. of ore; at normal speed the tram can deliver 500 to 600 tons of ore per day. The track-cable that was purchased at the time the tramway was projected suffered the fate of much other material in that the Government commandeered it after shipment had actually been made. Mr. Paxton, with characteristic resourcefulness, negotiated the purchase of a quantity of second-hand cable that had been used at a mining property in Arizona. Recently, this has been replaced by new cable.

The original traction cable was only $\frac{1}{2}$ in. diam. as compared with $\frac{5}{8}$ in. now used. This was too light for the work and frequent breaks resulted; the buckets would then collect in groups at points where the track-cable sagged. The task of repairing the cable and restoring

operation was not only costly, in that it required a large force of men, but it delayed haulage and frequently caused temporary shut-downs of the mill.

Trouble has always been experienced with the grips by which the buckets are attached to the running-cable, although the profile of the line is comparatively smooth and is not excessively steep. The original grips, designed for a $\frac{1}{2}$ -in. cable, failed to remain securely locked and slipped badly; this slipping, and the consequent wear, naturally aggravated the tendency of the cable to break. It was thought possible that the trouble from slipping would be overcome by substituting the larger cable and correspondingly larger grips, but even then the automatic locking device did not seem to function adequately. In an effort to remedy this trouble an extension was devised for the locking-arm at each of the terminals, whereby a longer, harder, and smoother pressure was applied to the grip-lever, by means of a long gently curving strip of boiler-plate forced down by sundry improvised springs. Marked improvement is noted but O. B. Camp, master mechanic for the company, is convinced that his own difficulties would be lessened and more regular operation obtained if he had a tramway in which the buckets were permanently attached by means of a clip to the traction-cable. It may be remarked that, though unusual, a number of such trams have been built, and operated successfully. The advantages are the impossibility of unlocking or slipping of the grips; and the uniform balance that results from having the buckets exactly spaced at all times. The disadvantage lies in the necessity for providing a moving chute for loading the buckets as they pass through the terminal without stopping. Any hitch or delay in the mechanism may result in the departure of an empty or a half-filled bucket. On the whole a properly designed grip is probably more desirable. It is not fair to condemn the Riblet grip because it gives trouble in this particular tram, for the reason that similar grips are working satisfactorily elsewhere. Just what the conditions are that cause the difficulty at Engels are not known.

Prior to September 1920 the per-ton mining costs were based on the quantity of ore milled. Starting with that month the basis was changed to 'tons of ore broken'. The following analysis of the cost covers, therefore, the last four months of 1920 only. During that period 142,402 tons of ore was mined and 86,021 tons was milled, leaving a net increase of stoped ore amounting to 56,382 tons. The figures, based on 142,403 tons, are as follows:

Item	Cost per ton		
	Labor	Supplies	Total
Machine drilling	\$0.5524	\$0.1673	\$0.7197
Shoveling and tramming.....	0.3793	0.0227	0.4020
Explosives	0.0197	0.2077	0.2274
Timbering	0.0867	0.0112	0.1279
Track and pipe	0.0189	0.0245	0.0434
Carbide and candles	0.0089	0.0089
Assaying	0.0122	0.0089	0.0211
Engineering	0.0112	0.0019	0.0131
General	0.0083	0.0035	0.0118
Loss on boarding house	0.1304	0.1304
Total	\$1.0887	\$0.6170	\$1.7057

(To be Concluded)

Chloride Volatilization Process

By Thomas Varley and C. C. Stevenson

*The chloride volatilization process is still in the experimental stage. The process has not been sufficiently developed to permit us to state definitely what place it will occupy in the metallurgical industry; the theory upon which it operates has received the attention of prominent metallurgists for the past twenty years, but the results of much of the experimental work done have not been published. The object of this paper is to bring the salient features of the process to the attention of the

posits from the chloridizing roast, recognized the possibility of making volatilization a major instead of a minor feature of the roast. He then made tests on a number of ores from different localities, the result of which showed the general application of the process. The main difficulty, as stated by Croasdale, was the lack of a suitable means for recovering the fume from the furnace gases. In 1913, Cottrell† announced his invention of the electrostatic precipitator, which solved the problem of separat-

LABORATORY KILN, WITH CHLORIDE INJECTOR AND BURNER

SCREW-FEEDER FOR LABORATORY KILN

industry, for the purpose of furnishing information and to encourage comment. A bulletin covering the work done at the Intermountain experiment station of the U. S. Bureau of Mines, at Salt Lake City, Utah, is in course of preparation.

The chloridizing roast is usually accompanied by appreciable losses, due to the volatilization of the metals as chlorides, these losses often running as high as 30%, depending upon the temperature, the character of the ores, and the associated gangue material. It was not until 1891 that Croasdale,† by observing flue and stack de-

ing the solids from the furnace gases. About 1915 O. C. Ralston, of the U. S. Bureau of Mines, began an investigation of the chloride volatilization process as a possible means of ore-treatment. Since that time the Intermountain station of the Bureau, in co-operation with the department of metallurgical research of the University of Utah, has gone extensively into the problem.

POSSIBILITIES OF THE PROCESS. The process is adapted to the treatment of oxidized, semi-oxidized, and carbonate ores of copper, lead, and silver, which are difficult to treat by gravity concentration or flotation.

*Abstracted from Serial No. 2247, U. S. Bureau of Mines.

†E. & M. J., Aug. 29, 1903.

‡M. & S. P., March 29, 1913; also Trans. A. I. M. E., Sept. 1918.

Gold that is present in ores has been readily volatilized. Zinc does not volatilize if an oxidizing condition is maintained. Excellent results have been obtained on zinc concentrate containing silver and lead; practically all the silver and lead have been volatilized, but little zinc. Experiments have shown that this is probably one of the best methods of making a clean-cut separation of lead and zinc. No great amount of work has been done on sulphide ores, the need of such a method for the oxidized and carbonate ores is more pressing. Experiments, however, carried out on sulphides are encouraging. When the sulphur content is more than about 5%, a preliminary roast is usually necessary.

METHODS OF EXPERIMENTATION. The ores are analyzed for their chemical and mineralogical constituents, the latter by the microscope in order to identify and determine the physical condition of the minerals. The chemical analysis reveals the various amounts of metals present, and the microscopic analysis shows in what minerals the metals occur—it is possible to determine accurately the size of crushing necessary to liberate from the gangue the greatest amount of mineral that can be recovered economically. The compactness or porosity of the ores in which the minerals occur is an important factor, the compact ores usually require finer crushing. After the degree to which the ore must be crushed has been determined, it is necessary to calculate, from assays and analyses, the amount of chloridizing salts that must be added to the charge, to ensure the presence of sufficient chlorine to unite with the metals and to effect complete chloridation and volatilization.

MUFFLE-TESTS. The assay muffle is usually used for this preliminary determination. Temperature varies with different ores, but when silver is present about 1050° C. is usually required; 100 gm. of crushed ore is mixed with a certain percentage of salt or calcium chloride. A number of such charges, contained in 5-in. or 6-in. roasting dishes, are then placed in the heated furnace. Several tests are made in which the varying factors are time of roast, temperature of furnace, fineness of crushing of ores, and amounts of salt and calcium chloride. The residues after roasting are weighed and assayed, and from these results the percentage of volatilization is calculated. In these experiments none of the fumes evolved can be caught.

ELECTRIC-TUBE TESTS. Tests are made by means of a horizontal electric furnace; a small boat containing the mixed charges is placed in a silica or porcelain tube, and then the tube is placed in the furnace. It is possible to pass air through the tube at any desired rate and also to collect the fumes and measure the gases.

LABORATORY VOLATILIZATION-PLANT. The plant consists of a rotary kiln, dust-chambers, a double-unit electrostatic-precipitator, and a Stevenson chloride-injector, constituting a complete miniature chloride-volatilization plant. The kiln has three speeds, either one, two, or three r.p.m. The speed affects capacity, ore transit rate, and dusting. The ore-feeder is equipped with eight different speeds, which permit variation in the rate of feeding the

ore from about 1½ to 12 lb. per hour. The rate of feed affects the capacity and length of time that the ore is in the furnace. The velocity of the gases is regulated by means of slide dampers arranged in the channels that convey the gas. The gas velocity affects the dusting, grade of fume produced, and the concentration of the chloridizing atmosphere in the furnace. The chloride injector has 48 different speeds, which will feed from 2½ to about 20 oz. of chloridizing reagents per hour. This large variation makes it possible to supply almost any desired quantity of chloridizing reagents to the ore in the heated zone of the furnace.

The treaters are constructed in two separate units of four and two pipes, respectively. These units may be used separately or collectively, which is equivalent to using either a two-, four-, or six-tube treater. The number of tubes used affects the velocity of the gas in the treaters and the clearance. The furnace is fired with a blow-torch, using artificial illuminating gas under low pressure, or oil and air at about 20-lb. pressure. The control of the temperature is satisfactory, any desired heat up to 1250°C. being maintained without difficulty.

Tests are made in the small laboratory plant both for research investigations and as preliminaries to the large-kiln tests. From 10 to 25-lb. samples are desirable for these experiments. The ore, with part of the chloridizing reagents, is fed into the upper end of the furnace by means of a mechanical ore-feeder; the remaining portion of the chloridizing reagents is injected directly onto the charge in the front or heated end of the furnace.

The large-kiln tests are usually preceded by a number of preliminary small-kiln tests, in order to determine a set of conditions that are most effective for the ore to be treated. From 200 to 2000 lb. of ore is usually employed in making these final tests. The following results are typical:

	Per cent volatilized Small kiln		Per cent volatilized Large kiln	
	Silver	Lead	Silver	Lead
Carbonate silver-lead ore.....	93	94	90	88
Oxidized silver-lead ore.....	85	94	90	92

The first tests made in the small furnace were conducted for the purpose of improving the extraction of silver from an ore of approximately the following analysis: 7.4% lead, and 6.80 oz. silver per ton. Previous work had been done on this ore, resulting in good extraction of the lead, but the result on silver was unsatisfactory, 60 to 65% being the best obtainable. The usual method of making volatilization tests is to mix the ore with the chloridizing reagent or reagents, and to feed the mixture by a screw-feeder or other suitable means into the cool end of the furnace. The rotation of the kiln and the slope of the frame on which the furnace is mounted causes the charge to migrate downward toward the front and heated end. When the charge becomes heated a reaction takes place between the metal-bearing minerals and the chloridizing reagent, which effects a chloridization of the metals with a subsequent evaporation of the metal haloid.

CHEMICAL REACTIONS. There seems to be a difference of opinion as to the most probable chemical reactions that

take place. It is our opinion that different reactions are involved, depending on the chloridizing conditions brought about in the furnace. The three following equations show the reactions that are most likely to take place, assuming silver as the metal to be chloridized and volatilized.

No. 1 (According to Croasdale):

In the presence of sulphates, this reaction would in all probability take place during some stage of the roast.

Experiments have shown that silver, lead, and other metals can be chloridized and volatilized in the absence of sulphur. This reaction, represented by Equation 2, would take place to some degree, provided that the temperature were high enough and all the salt had not volatilized as sodium chloride before the charge could reach the temperature necessary to promote the reaction; *R* represents the metal volatilized.

No. 2:

It is doubtful whether this reaction would take place if the sodium oxide had nothing with which to combine. It is known that sodium oxide is difficult to form; however, if silicates in the gangue are available for combining with sodium oxide, to form a sodium silicate, it is possible to get a reaction with part of the salt. The following reaction represents the chloridizing of most of the metals present in an oxidized ore.

No. 3:

On the assumption that the equations given are correct—even to the complete chloridization of all the silver in the ore at some time during the thermal treatment—there remains a condition that would be likely to prevent complete volatilization of the silver. Is the metal volatilized immediately upon being chloridized or is a certain time required for the metal haloid to evaporate? The action of the chloridizing roast preparatory to leaching is sufficient evidence that the chlorides are formed at relatively low temperatures and without being completely evaporated.

The following reaction could be expected to occur with at least part of the metal haloid at increased temperature.

As the charge passes through the furnace, the temperature continues to increase, and part of the salt rapidly volatilizes as sodium chloride, while the remainder enters into the chloridizing reactions. The result is that the metallic chloride, which does not evaporate rapidly in the zones of lower temperature, is conveyed into the hotter regions, where the chloridizing atmosphere becomes lean. It would not require a strong imagination to conceive a decomposition or reversal of reaction, in which the metal would be left with the calcine as a non-volatile compound or element. Experiments have shown that the silver re-

maining in the calcine from a high-temperature roast (1000° C.) is not present as chloride.

It may be that some of the silver compounds occurring in the complex oxidized ores are not chloridized at the low temperature. If this were the case, it could logically be assumed that the chloridizing reagent or reagents might be volatilized or decomposed and dissipated before the silver would be in an available state to be chloridized.

COTTRELL APPARATUS

From this reasoning, it appears that the most logical method of volatilizing metals from an ore would be to place the charge, consisting of ore and part of the chloridizing reagents, in the furnace, to permit the charge to become heated to the proper temperature and then to supply the remaining portion of the haloid salt to the heated charge in the zone of high temperature. This method of supplying the chloridizing reagent would produce a highly chloridizing atmosphere directly where it is needed.

The following is the record of the first test made, wherein the chloridizing reagents were supplied to the

charge in the front and heated end. This test was made for the purpose of chloridizing and volatilizing the lead and silver in an oxidized zinc ore, leaving high-grade zinc calcine. The charge was fed into the feed end of the furnace by means of a screw-conveyor. In addition, 4% of hydrated calcium chloride was fed by hand at regular intervals to the charge in the fire-box, instead of introducing it with the charge. The temperature was 1010°C. Steam was passed into the fire-box. Good oxidizing conditions were provided. Dense fumes were evolved, especially when the portions of chloridizing agent were supplied to the charge in the fire-box. The following assays show the result:

	Assay of material			Per cent volatilized	
	Silver oz.	Lead %	Zinc %	Silver	Lead
Original ore (10 lb.)	0.8	7.4	32.6
Calcine before addition of CaCl_2	1.32	1.58	...	74.3	73.0
Calcine after addition of 4% of CaCl_2 , $2\text{H}_2\text{O}$	0.68	0.63	44.86	90.3	92.0

These results are conclusive, and show definitely the advantage of adding part of the chloridizing reagent at the hottest point in the furnace, thereby giving a strong concentration of chlorine vapors at the critical temperature and time at which the chemical reactions take place.

fusion of salts that are later decomposed at the high temperatures. The evaporation of moisture from the ore causes precipitation of the soluble salts and the deposition of suspended matter, both of which act as a binder, and crust the particles of ore together.

The low-temperature fusion of sundry salts—either those contained in the ore, those supplied as chloridizing reagents, or the salts formed from the reactions—serves as a binding medium and causes some trouble in the feed end. Baking forms rings of crusted ore in the feed end of the furnace, which continue to build up on the lining until the ore flows back into the dust-chamber. Baking is not a serious difficulty. The crust is easily broken and a heavy drag or rabble properly placed will prevent its formation.

The rate of ore-travel should be as slow as possible in order to reduce dust-losses and prevent a high insoluble content in the fume. A linear travel of about 15 ft. per minute in a commercial kiln is usually sufficient to mix the charge and maintain the desired capacity. The gas velocity should not exceed the speed necessary to carry away the combustion gases and fume. High velocity causes a high dust loss, low-grade fume, and a dilute

SUMMARY OF RESULTS ON VARIOUS TESTS

Ore	Head Assays						Reagents		Per cent Volatilized		
	Gold oz.	Silver oz.	Lead %	Zinc %	Insoluble %	Sulphur %	NaCl %	CaCl_2 , $2\text{H}_2\text{O}$, %	Gold %	Silver %	Lead %
Oxidized zinc concentrate	...	6.80	7.40	32.6	13.6	...	6	6	...	85	80
Oxidized silver-lead ore, Utah	0.07	9.39	15.7	1.25	62.0	4.47	10	10	...	80	89
Silver-lead ore, California	...	9.66	1.07	1.83	50.0	4.92	5	10	...	80	...
Oxidized silver-lead ore, Nevada	0.03	3.56	5.35	5	10	70	87	80
Oxidized silver-lead ore, South America	...	12.0	1.60	...	77.2	0.86	5	7	...	75	80

SINTERING. Sintering is the result of a semi-fusion of the charge that may be caused in several ways. Most frequently the gangue in the ore is so composed as to be self-fluxing; when heated it begins to fuse at a moderately low temperature. A variation of this type of ore would be one composed principally of non-fluxing gangue material, but accompanied by ingredients in the form of dust that would flux the main gangue minerals. Gossan, composed of limonite, hematite, and other iron minerals, would be an example. Sintering is promoted by the chloridizing reagents, common salt being especially active. The salt, upon decomposing, liberates its chlorine and combines possibly as a silicate or sulphate, both of which are fusible at the temperatures required to volatilize silver chloride. Most sulphide ores tend to sinter, which results in sealing the metal within the ore particles and protects it from the chloridizing gases, thus causing low extraction. This objectionable feature is usually overcome by the use of some inert nonfusible material such as limestone. The addition of 5 to 15% of lime-rock will prevent sintering in some of the worst ores. The use of calcium oxide would be still better, because there would be no carbon dioxide to dilute the gases.

BAKING. In making preliminary muffle- or tube-tests, baking and sintering should not be confused. Baking is the result of a crust-forming action in the charge, taking place in the region of lower temperature in the furnace. Two causes are responsible for most of the baking that occurs: the evaporation of moisture, and the temporary

chloridizing atmosphere over the charge in the furnace. A velocity of 10 to 20 ft. per second is usually sufficient in a properly designed kiln. The necessary temperature required for chloridizing and volatilizing the metals from an ore depends entirely on the metals to be volatilized. Copper and lead will volatilize at much lower temperatures than gold and silver. However, a temperature of 1000°C. should completely volatilize all the metals except zinc, providing the charge does not sinter. The time required to evaporate the metal haloids depends on the temperature and concentration of the chloridizing atmosphere. Forty to sixty minutes, under proper temperature and chloridizing conditions, should be sufficient.

SUGAR OF ANTIMONY is used in making furniture polish, and the chloride (SbCl_3) is used in the preparation of fireproof preservatives of wood, paper, and textile fabrics, such as creosote, pitch, tar, and asphalt, states a U. S. Geological Survey bulletin. Antimonate of lead, containing an excess of lead oxide, known as Naples yellow, is used in oil paints and in the glass and ceramic industries. Tartar emetic and antimony fluoride are employed as mordants in dyeing. Tartar emetic and antimony trioxide are employed medicinally. Antimonial lead carrying 12 to 13% of antimony is employed in the manufacture of bullets. Antimony sulphide is almost universally used as a constituent of primers in shells and cartridges, and to produce on explosion a dense white smoke, which is of service in range finding.

Repairing a Wood-Stave Pipe-Line

By G. A. Joslin

In 1919 the Ramshorn Mines Co., operating at Bayhorse, in Custer county, Idaho, replaced the old power-plant used in the 'nineties with a modern hydro-electric equipment, which furnishes power for mine and mill. The old open flume, which contoured the steep hillside from dam to head of penstock, gave way to an 18-in. pipe-line laid on the flume grade; at the end of the grade-line pipe a standpipe was placed and a new penstock laid down the hillside to the power-house. All the pipe was machine-banded wood-stave of the inserted-joint type. The drop from dam to head of penstock is 68 ft. and from this point to the power-house is 354 feet.

in plan. Wood-stave pipe once laid and set should not be disturbed. The first problem therefore was to find a way of inserting fittings without moving the two pipes. The standpipe being of short length, 180 ft., and easily moved entire, did not affect first considerations. Drawings were made showing the positions of the pipes as they entered the wooden box. A standard long-radius elbow connected to the end of the penstock was laid out and a special tee designed so that the centre-line of its outlet fell in a plane with the centre-line of the penstock, the outlet being designed long enough to take up the offset distance between the two pipes and permit the

The original plans called for a cast-iron tee at the junction of the grade-line pipe, standpipe, and penstock, but on the advice of the construction superintendent a reinforced-concrete junction-box was substituted. Construction was carried on with all of the wastefulness, carelessness, and inefficiency of labor for which we blame the War. As a result the concrete box failed late in the fall of 1919. Winter was coming on, time was short, so a wooden box tied together with rails and rods was constructed hastily. This held satisfactorily for a year, but during the winter of 1920-21 was the cause of increasing trouble and was recently replaced by a cast-iron tee and elbows.

Had the grade-line pipe and the penstock been in the same plane and at right angles to each other at their intersection, any standard cast-iron tee would have sufficed, but the penstock came out at the bottom of the box, whereas the grade-line pipe entered at the top, and the two pipes intersected at an obtuse angle when viewed

centre-line of the run of the tee to be a continuation of the centre-line of the grade-line pipe. One run of the tee was designed to connect with the grade-line pipe, the other run with the standpipe, which was laid up the hill on the natural slope to a point of approximately the same elevation as the intake end of the grade-line pipe at the dam, and the outlet to connect with the elbow of the penstock. By being able to turn this elbow about the axis of the penstock and the tee about the axis of the grade-line pipe it was possible to bring the flange of the outlet and the flange of the elbow together without moving the two pipes. The design, of course, required cutting the pipes at the correct distance from the outlet of the tee and from the flange of the elbow to admit the hub-flanges used to connect wood-stave with standard pipe-fittings.

Because of the difficulty of obtaining exact measurements of the pipes as they entered the wooden box, the drawing was not considered sufficiently accurate to use

in marking off the points where the pipes were to be cut. To cut off an inch too much would be serious. To obviate the necessity of lifting the heavy cast-iron fittings into place for a try and cut, wooden forms were made of elbow and tee, and a form for each hub-connector identical with the cast-iron hub as to flange end but having on the hub end a jacob staff to slide into the open pipes. As soon as the wooden junction-box had been dismantled, the wooden forms were placed in position, the staffs of each hub-connector form extended into the pipes, allowance made for the length of the cast-iron hubs, and the pipes marked and cut. The heavy cast-iron fittings were then assembled and slipped into place as simply as a final Euclidean equation. The standpipe was then moved slightly and by means of a second long-radius elbow attached to the run end of the tee opposite the grade-line pipe. The whole job, including the wrecking of the wooden junction-box with due regard to salvage of material, was completed in 36 hours.

I believe it is worth mentioning here that most tee connections on similar installations between grade-line pipe, standpipe, and penstock are incorrectly made; that is, the outlet of the tee is usually connected to the grade-line pipe, one run to the standpipe and the other to the penstock. The function of the standpipe, of course, is to relieve the line of sudden surges—great increase of pressure—due to a sudden closure of the gate at the power-house or other causes that check the movement of the column of water. If the run of the tee connect with the standpipe and with the penstock the full force of the grade pipe-line water is thrust against the wall of the tee. If the run of the tee connect the grade-line pipe and standpipe in a straight line the moving water can rush smoothly into the standpipe entrance—finding relief up the pipe—and take the momentum effect from the penstock. This, I believe, is a well-known principle in steam-engineering used in placing air-chambers in pump-lines and it is rather odd that it is so often disregarded in laying water-pipe for power purposes.

Manganese in Spain

*Manganese ores occur in the provinces of Ciudad-Réal, Gerona, Huelva, Mureia, Oviedo, Sevilla, and Ternel. According to official statistics, 837,000 tons of such ores was mined in Spain during the years 1881-1909, nearly all of this coming from the Huelva carbonate deposits, although work on these was almost suspended for the first ten years of that period. The annual production exceeded 100,000 tons during the period 1897-1900, but afterward declined irregularly, averaging only 7229 long tons for 1909-1911, but amounting to 17,120 tons in 1912. As a result of new discoveries and more intensive work during the war period, the yearly output has shown a considerable increase since 1916. Spanish manganese ore is commonly sold on the basis of its percentage content of manganese dioxide. In addition

to the production of manganese ore there has been a considerable output in the Cartagena region, province of Mureia, of manganiferous iron ore containing from 10 to 20% of manganese and 20 to 25% of iron, the mineral occurring in association with hematite. It is used only when the content of silica is not in excess of 10%, most of the production going to England.

PROVINCE OF HUELVA. The manganiferous deposits of this province have been described by Hoyer.[†] They are situated on the northern slopes of the Sierra Morena, being in the form of lenticular masses conformably interbedded among clay-slates and porphyroids, and belonging in part at least to the Culm formation. The length of these masses is sometimes over 3000 ft., but seldom more than 500 ft.; the breadth sometimes exceeds 300 ft., but averaging about 100 ft. For the most part the lenses consist of banded or massive compact rhodochrosite and rhodonite, associated with which are ferruginous silicates and chert. The carbonate and silicate ores are oxidized to pyrolusite and psilomelane for an average depth of about 65 ft. below the surface. The carbonate ores contain from 28 to 45% of manganese, 3 to 7% of iron, and 5 to 15% of silica; the silicate ores contain 39 to 45% of manganese and 20 to 22% of silica. Mining operations started in 1858, but were almost suspended between 1881 and 1891.

PROVINCE OF CIUDAD-RÉAL. An occurrence of bedded manganese ore in the Miocene rocks of the plateau of La Serena, near Val de Peñas, has been described.[‡] The ore consists in greater part of psilomelane, and is stated to contain from 40 to 60% of manganese, 1 to 20% of silica, 0.098 to 0.272% of phosphorus, 3% of oxide of iron and alumina, and 0.14 to 0.37% of cobalt. The deposit, which has an average thickness of about 4 ft., has hitherto been worked only in open-cuts.

PROVINCE OF TERUEL. Deposits of silicate ore, said to contain 33% of manganese and 30 to 37% of silica, were discovered in this province a few years ago, and ore therefrom has been shipped to Belgium and Luxembourg for smelting with aluminous iron-ores.

PROVINCE OF OVIEDO. At Covadonga a group of mines is being exploited by the Asturiana Mines, Ltd. The ores produced are (a) manganese ore, (b) iron ore, and (c) manganiferous iron-ore. The deposits occur as a capping on limestone, the ore being covered to varying depths by an overburden of boulder clay. The ore is won either by open-cast working after the removal of the clay, or by mining, the method depending on the thickness of the overburden. The product is washed, and the resulting minerals are passed over a picking-belt, the manganese ore and the iron ore being separated by hand. The remainder of the mineral, which is too small for hand-picking, is a mixture of pieces of iron ore and manganese ore, and is classed as manganiferous ore. Statistics of production are not available.

REVIEW OF MINING

BILL FOR REVISION OF THE MINING LAW PRESENTED IN CONGRESS

S. S. Arentz, Representative from Nevada, has introduced a bill providing for revision, amendment, and codification of the mining laws. The bill is practically identical with the draft prepared by a committee of engineers appointed by the Bureau of Mines in 1917 and headed by W. R. Ingalls. The bill consolidates and codifies existing mining laws and embraces amendments conforming to the wishes of the industry. A summary of the draft presented to the House Mines and Mining Committee appeared in the 'Mining and Scientific Press' of June 18.

KENNECOTT COPPER IS PRODUCING 5,000,000 LB. PER MONTH

The Kennecott Copper Co. has curtailed production, but not to the extent that other producers have. The output last month was 4,867,520 lb., making 69,758,760 lb. for the first six months. If the output approximates on the average only 5,000,000 lb. per month throughout the rest of the year, Kennecott should produce 100,000,000 lb. of metal in 1921. Last year's production was 117,017,340 lb. Kennecott can turn out its metal at less than 11c. per pound, a low cost that few big producers can equal, aside from Miami and Cerro de Pasco, and can, therefore, make some profit even with copper under 13c. per pound. Stagnation in the metal market prompted the corporation to omit the usual quarterly distribution of 50c. per share earlier in the year. Dividends are not expected to be resumed until the corporation is able to increase operations and produce funds sufficient for that purpose. Ahead of the 2,787,000 shares of Kennecott outstanding there are \$15,000,000 7% bonds which were issued in 1920 to provide additional working capital. This calls for an interest charge of \$1,050,000 annually. Kennecott is getting at the annual rate of \$1,233,008 from its investment of 616,504 shares of Utah Copper, more than enough to cover the interest on its bonds. Even if Utah decides to again conserve its cash and reduce the 50c. quarterly dividend on its shares at the next meeting, Kennecott ought to earn more than enough this year to pay all charges and interest.

COMPARATIVE FIGURES ON COPPER PRODUCTION

The following statistics appear in the 'Boston News Bureau'. Though not entirely accurate they are interest-

ing in that they are indicative of the present condition of the copper mining industry.

RULING ON MINE-DEPLETION CALCULATIONS

The Internal Revenue Bureau at Washington has issued the following decision in regard to the re-valuation of mineral deposits: "Held, that the M Company is not entitled to a new valuation for depletion in a known mine; that a discovery cannot be made of any 'probable' or 'prospective' ores which had been or could have been included in the previous valuation, and that the regulations do not recognize a discovery for the purpose of depletion as the result of improved processes of treatment of ores making commercially valuable ores which were theretofore valueless. It is further held that if bodies of zinc ore not theretofore known to exist were discovered within the meaning of the regulations, the fact that the explorations were stimulated by recent improvements in metallurgy which made them commercially valuable for the first time would not bar a claim for discovery, and that if the original valuations of the M Company were based upon estimates of recoverable units, which included only the ores in sight and blocked out, the properties may be re-valued as of the basic date in accordance with the provisions of the present regulations and the depletion rate determined accordingly."

STAR V. FEDERAL LITIGATION MAY BE SETTLED

A compromise of pending differences between the Star and Federal Mining companies, operating in the Coeur d'Alene district of Idaho, for settlement of the damages awarded by a recent decree of the United States Circuit Court of Appeals to the Star company for infringement of its rights, is probable, according to reports. Under the decree of the court, the principles of the Star's claims against the Federal were sustained, and the case remanded to the lower court for determination of the amount of damages. Color is lent to the rumor that a settlement is near by the presence at Wallace of William Wynass, general auditor of the Federal Mining & Smelting Co. Mr. Wynass arrived at Wallace last week, and it is understood that he now has under consideration for checking a proposition for determination of the amount of damages, submitted by the Star people. F. W. Bradley, president of the Bunker Hill company, whose interests are involved in the Star side of the controversy, is also at Wallace. That the Federal will accept

Company	War maximum		Present operations

*Monthly. †Annually.

in full the terms proposed by the Star is not believed, but it is thought that by accepting some of them, and leaving other matters still in controversy to the determination of a master in chancery, an end is in sight to the protracted and costly litigation which for several years has involved these two properties.

The Star brought suit in the early part of 1917, alleging trespass on the part of the Federal and removal of ores from Star ground. The case was tried before Federal Judge Dietrich of the United States court, sitting in Wallace, and he handed down a decision in favor of the Federal. The plaintiff company appealed. In May 1920 the higher court reversed Judge Dietrich and sent the case back to him for determination of the amount of damages to be paid by the Federal to the Star.

THE WORK OF THE BUREAU OF MINES IN ALASKA

For the purpose of fostering a more rapid and better development of the mining industry in Alaska, the U. S. Bureau of Mines is re-organizing its work in that Territory. D. A. Lyon, supervisor of stations, and George S. Rice, chief mining engineer, for the Bureau, are now in Alaska on a tour of inspection to determine in what manner the Bureau of Mines can best assist the mining industry. It is proposed to divide the Territory into four districts, each being in direct charge of a Bureau engineer. For the purpose of proper correlation of the work, especially as to keeping its main purpose in view and providing service for particular mining camps which may be isolated or lie on the border between two districts, a supervising mining engineer will be in general charge of the four district-engineers. Owing to lack of funds, one of the district engineers will for the present discharge the duty of supervision. The Bureau of Mines experiment station at Fairbanks will be continued as a headquarters and clearing-house for district-engineers.

District 1 has been assigned to Bert W. Dyer, who will also continue to discharge his duties of Federal Mine Inspector of Alaska. This district embraces the south coast, in the Copper River basin and, for the present, the Katalla oil-fields and south-eastern Alaska.

J. A. Davis will continue to serve as superintendent of the Fairbanks station and, in addition, will be in charge of District 2, which consists of the territory tributary to the Government railroad from Seward to Fairbanks.

District 3 consists of interior Alaska, comprising the Yukon and Tanana basins. This district has been assigned to K. T. Sparks, assistant mining engineer. District 4 is the Seward Peninsula. No assignment of an engineer for this district has been made as yet. It is believed, however, that the best way to assist the mining industry in this district lies in the development of a practical and economical method of cold-water thawing. Charles Janin, consulting engineer for the Bureau, is now compiling and studying the results of experiments made by the various companies, preparatory to investigation by the Bureau.

PRESENT SMELTING OPERATIONS IN MEXICO

According to an official of the American Smelting & Refining Co., who has been making a tour of the plants of that company in Mexico, the smelting situation has improved. He said that five of the six furnaces of the smelter at Chihuahua are now in operation and that the sixth will be blown-in in a few days; one of the ten furnaces of the smelter at Aguas Calientes is in operation; two of the four furnaces of the smelter at Matehuala are in operation and preparations are being made to blow-in the third furnace. None of the furnaces of the company's smelters at Monterrey and Asarco are in operation and it is not known when these plants will be re-opened. This will depend altogether upon the condition of the metal market. The company is obtaining much of the ore for the Matehuala

smelter from its Dolores mines. The ore supply for the smelter at Chihuahua comes from the mines at Santa Eulalia and from Parral, the latter being in the form of concentrate. The American Smelting & Refining Co. has entered into a new contract with the National Railways of Mexico for the handling of its freight traffic. It is stated that the practice of operating private freight trains is to be abolished or at least materially modified.

ALABAMA

University.—The School of Mines of the University of Alabama offers five fellowships in mining and metallurgical research in co-operative work with the U. S. Bureau of Mines. The fellowships are open to graduates of universities and engineering schools who have the proper qualifications to undertake research investigation. The value of each fellowship for 1921-1922 is \$540 per year of nine months, beginning October 1. Fellowship holders will be required to register as graduate students and to become candidates for the degree of Master of Science in Mining Engineering or Metallurgical Engineering unless an equivalent degree has previously been received. The fellowships have been established primarily for the purpose of undertaking the solution of various problems being studied by the U. S. Bureau of Mines that are of especial importance to the State of Alabama and the Southern States.

ALASKA

Hyder.—The new concentrator at the Premier mine has been started, and is being brought gradually up to capacity. This is the first unit of a larger plant; it has a capacity of 100 tons per day. There is ample feed for it in the way of cullings from rich ore that has been shipped to Tacoma.——Messrs. McKenzie and McCallum, of Victoria, are establishing three tent camps at different points up the mountain on the M. C. group. Surface ore carries visible gold and silver.

ARIZONA

Katherine.—Development work in the Katherine Extension shaft, placed near the line of the Katherine mine, is progressing under favorable conditions for the early discovery of pay-ore. A station has been cut at a depth of 250 ft., a depth which corresponds closely to the 200-ft. level in the Katherine shaft, and a cross-cut is now being driven to contact with the north-east continuation of the Katherine fissure. The Katherine Extension management plans to drift along the fissure to find the lenses of rich ore.

CALIFORNIA

Bangor.—The old adits and drifts in the Blue Lead and Catskill mines are being cleaned out preparatory to operation by a corporation of which F. F. Ford is president. The land overlying the old channels is said to be suitable for raising citrus and deciduous fruits. A unique plan for combining the business of farming with mining is being tried.

Grass Valley.—Following the agreement reached between the mine operators and the Mine Workers Protective League, whereby a board of arbitration is to settle the wage controversy, operations are rapidly returning to normal. At the Empire mine a full force of miners is at work; it is not the intention to resume work at the Pennsylvania mine for the present. The North Star mine is gradually increasing its production. At the Idaho Maryland the water-level is now reaching the lowest point following a long period of unwatering and repairing. Allan P. Matthew, an attorney of San Francisco, has been selected by the mine operators and W. H. Southcott, Mayor of Grass Valley, has been named by the workers to serve on the board of arbitration. These two will select a third member.——A drift on the 100-ft. level from the new shaft of the South Star mine has broken into the old shaft sunk fifty years ago. According to records,

the old shaft was in good ore, and A. J. Johnson, who is now re-opening the mine, expects to unwater the workings.

Redding.—The Shasta Zinc & Copper Co. has found that the zinc oxide produced at its smelter at Bully Hill is not quite pure enough. So the product is treated in a refining or re-smelting plant. It was hoped that the bag-house would turn out pure zinc oxide. Six hundred tons of zinc oxide is on hand. This is produced at the rate of 30 tons per day. A small refining plant—a pilot plant—has been treating two tons of oxide per day. This finds ready market. A larger plant is under construction—one that will refine the daily smelter product of 30 tons. This new plant will be completed in about two months.

Edmund Jussen of Berkeley has recently taken a bond from F. M. Archer on the old Chicago silver mine near Igo and has set a force of men at work on development. The Chicago was a famous producer before silver was demonetized. Archer in the last few months has found some ore

tension of the Vulcan tunnel on Collier mountain, in the Snake River mining district. The company own a large acreage of placer and lode claims; ore produced from shallow workings on the lode claims has been shipped. The ore closely sorted assayed \$265.70 gold and 40 oz. silver per ton. A vein 20 to 40 ft. wide has been opened in the tunnel, and, excluding the richer stratum, the remaining rock is reported to be of from \$7 to \$12 grade.

Cripple Creek. Mineral hill in the western end of the district has a producer in the Engineer's Luck, a fractional claim. Thompson & Mack, who opened ore on the Ella W., have repeated and are mining ore from a strong vein in the brecciated area that will assay at about one ounce of gold per ton. A 30-ton shipment was sent down to the Golden Cycle mill recently.—A caved stope above the second level of the Damon shaft of the United Gold Mines Co., on Ironclad hill, is producing. Syart Cox and associates, lessees, have installed an electric hoist and are raising and

Hyder, Alaska. The Port for the Premier Mine in British Columbia

and has opened the mine and made it ready for active development.

Sutter Creek.—A new hoist has been hauled to the Central Eureka mine. Concrete for the foundations is being poured. A 4½-ft. vein of good quartz ore has been found in the south drift on the 3900-ft. level near the line between the Central and South Eureka properties. The Central Eureka has the South Eureka ground under option.—The work of dismantling the surface plant at the old Eureka mine has been completed. Pumps have been pulled and the track removed, and the mine will be allowed to fill with water.

Tuolumne.—The Phoenix Mining Co. has been organized by James Leary and B. A. Whitaker, assisted by Henry Manning and other Oakland capitalists. The Phoenix mine, formerly known as the Empire, situated across the north fork of the Tuolumne river, will be developed. A gas-engine will be used to unwater the 200-ft. shaft, which it is planned to sink another 100 ft. before cross-cutting.

COLORADO

Apex.—Timbering found necessary in the Barriek tunnel has delayed development of the vein recently opened by the Saco De Oro company.—The Evergreen Mines Co. has called the annual stockholders meeting for election of directors, to be held in Denver, August 16.

Breckenridge.—The Vulcan Tunnel Syndicate, recently organized by Denver and Summit county men, plans ex-

shipping about 50 tons daily that averages about \$15 per ton. Samples assay from \$8 to \$40 per ton.—The Buena Vista workings, Isabella Mines Co., are again active under lease. A shipment was made recently.

Silverton.—Holdings of the Allerton Mining Co. in the Gladstone district have been acquired by the Golden Consolidated Mines Co.; preliminary work has been completed and development will be undertaken.—Supplies have been sent to the Toltec mine and a large force has been engaged for development.

IDAHO

Coeur d'Alene.—Development has been resumed by the Washington Mining Co. on its property in the Coeur d'Alene. It is surrounded by the Ajax, Ambergris, Happy Day, and C. & R. properties. The lower tunnel, 870 ft. long, is within about 50 ft. of the point vertically under the orebody in the upper tunnel. Operations have been resumed on the Waverly mine, in the Florence district. The property includes a well equipped mill that is ready for operation.

Ore shipments from the Sidney property on Pine creek to the Bunker Hill smelter have been made recently. The ore will average 50 oz. silver and 47% lead. More than 100 tons have been mined since the new organization took over the mine.

The Bunker Hill smelter at Bradley shipped 60,000 oz. of silver to the mint at San Francisco recently. The plant is handling about 100 tons of ore daily in one furnace. Besides the Bunker Hill mines, the Hecla, Caledonia, Sierra

Nevada, and Sidney companies and lessees at the Last Chance and on Big Creek are supplying ore.

Hailey.—The Bunker Hill & Sullivan company has completed the installation of a compressor on its property and is advancing the Crego-Bullion tunnel. This tunnel has a length of 2000 ft. and will be extended 500 to 1000 ft., it is said.—Ore bodies of promise are reported to have been found on the Utah-Bellevue and at the south end of the Minnie Moore. The work on the Utah-Bellevue disclosed a body of ore 41 ft. wide, mainly of milling grade. The ore contains silver and lead, and some zinc. The recently discovered orebody on the Minnie Moore is 46 ft. wide and its chief metal content is silver and lead. The scene of the disclosure is a large open-cut made many years ago.

Lenia.—The Idaho Gold & Ruby Mining Co. is nearing a highly interesting stage in its operation. Three giants are pounding on the high banks and 'knocking-down' gravel at the rate of 50,000 cu. yd. per day. This gravel is dropping into the canyon, from which it will be driven into the sluice-boxes as soon as the water of the creek is low enough. An old-fashioned sluice test, made on two and a half yards of gravel, yielded about \$2 in gold.

Mackey.—Development has been started by the Mt. Sullivan company at its property in the Alder Creek district. A new adit will be driven to cut the ore at a depth of 525 ft. Samples assaying 20 oz. silver and 30% lead have been obtained in the upper workings.

Talache.—U. B. Hough of Spokane has been placed in charge of construction at the property of the Armstead Mines Co. of Talache. A contract has been let to build a 150-ton mill; also a contract for electric power has been signed and the staff of the mine has been enlarged and reorganized. H. H. Armstead, head of the company and largest stockholder, reports that intensive development work in the mine will be done while the mill is being constructed. The company has 100,000 tons of ore that will average \$23 in silver and \$2 in gold, besides some lead and copper. It will cost \$11 per ton to handle it. The mill will concentrate 150 tons per day into 25 tons of concentrate. Daniel G. McLachlan is mine-superintendent. Power will be secured from the Washington Water Power Co. of Spokane, through the Mountain States Power Co. at Sandpoint.

MICHIGAN

Calumet.—A cargo of 900,000 lb. of copper was taken out by steamer on July 20. Of this amount, 300,000 lb. was Calumet & Hecla metal for export to France, while the remainder of the shipment was copper from the Michigan and Quincy smelters. The export copper completed a 600,000-lb. order, the first 300,000 lb. leaving on July 16. But little inland domestic business is being done.

Houghton.—Both Mohawk and Wolverine have had little difficulty in holding their organizations intact and as a result both are at capacity production. Mohawk is sending 2600 tons of 'rock' to the mill daily, while Wolverine averages 1000. Sinking has been resumed in No. 1 shaft, Mohawk, and No. 4 and 6 also are being deepened. A full program of opening work is under way in all of the operating shafts. Wolverine is still mining the shaft pillars on the 38th, or bottom, level, a work that has been under way for several months. It will take years to exhaust the mine at this rate. None of the old openings is filled with discarded 'rock', which is used as filling in mines that work out the vein entirely as they go, so no obstacles present themselves in removing the pillars. Mohawk is managing to make a new dollar for an old one at the present price of copper, while Wolverine has its costs down to within a cent of the prevailing price.

MISSOURI

Joplin.—Efforts are being made to get the zinc operators

of this district to agree on a proposition to shut-down for a period this summer as a means of stimulating the market. Trouble is being experienced in getting a few, who are making profits on their present operations, to agree to the move. Continued operations have resulted in a large supply of ore being piled up at the mines, and operators declare that unless a movement is started to curtail the output they cannot expect to see a betterment of prices for at least another year. The plan as outlined at present is to shut-down immediately and remain closed until the middle of September.

MONTANA

Butte.—The Butte & Superior Co. has commenced drifting on the 2200-ft. level of its Black Rock mine. The objective is the copper-bearing ore-shoot that has been developed on the 2050-ft. level. Recent progress on this level has been encouraging for the development of a good-sized body of copper ore.

Development work is being continued by the North Butte company. From five to six feet of ore on the 3400-ft. level in the Edith May vein is reported. The ore has a copper content of about 9% and the showing is improving in the face of the drift, encouraging the belief that the body of ore in evidence on the upper level will be picked up in the lower workings. Cross-cutting north from the Granite shaft for the Jessie, for the north and south Croesus vein is planned. Raising out of the Spectacular shaft from the 3200-ft. level to the 3000 shortly will be undertaken.

Jens.—It is reported that the Butte & Western Co. is planning to build a mill at its Forest Rose mines.

Race Track.—The main adit of the New Champion mine made connections with the old shaft on July 15 on the 600-ft. level. When the old mine is completely drained, development work will be started, and much of the ore which was opened up 35 years ago will be mined through the new workings. Exploration of the old shaft to the 500-ft. level shows that the mine is in good condition, and it is believed that mining on the 600-ft. level can be carried on without many repairs.

Superior.—New milling machinery is being installed by the Gold Sunset Mining Co. at its property on Cedar creek. The owners are confident that they have solved the problem of treating the ore profitably.

NEVADA

Divide.—Work has been resumed by the Tonopah Divide with a crew of strike-breakers.

Ely.—E. P. Bowman announces that the Wyoming Mining & Milling Co. will start the company's fifty-ton mill. Ore from the dumps, worth \$11 to \$14 per ton, will be milled first; the stopes will be opened in the meantime.

Goldfield.—A winze 20 ft. deep in the orebody opened recently in the Silver Pick lease on the Red Top is in a 4-ft. width of \$100 ore; ore of this grade is being broken for shipment at a rate of five to six tons daily. The winze is being sunk with a windless and it will only be sent deep enough to give a good idea of the dip and strike of the vein. Two carloads of ore, 90 to 100 tons, will soon be shipped from this orebody, and two more are broken in another orebody below the third level and south of the shaft. The ore south of the shaft assays \$18 to \$20.—Donald and Giles, Florence lessees, are doing development work. The rich foot-wall seam apparently has flattened under the drift in which their find was made and they are cutting a station in preparation for following it. The seam on the hanging wall is breaking \$100 for a width of 3 ft. No further stoping has been done recently. The Cracker Jack continues drifting north from a 35-ft. winze from the 530-ft. level. The Red Hill is driving north-east into the Florence. Woodward has temporarily discontinued work on the 65-ft. level

of the Reilly block and is now working at 110 ft., where he is using an air-drill.

Gold Hill.—Connections between the Belcher and Yellow Jacket mines of the United Comstock company have been made and driving of the transportation tunnel is proceeding from nine headings. Connections have greatly improved ventilation and facilitated more rapid work.—The Comstock Reliance Co. reports development of a vein of shipping ore for 100 ft. The vein ranges from two to three feet wide with gold predominating. Where the lode is intersected by a cross-vein, 12 to 18 in. wide, a winze is being sunk.—The clean-up of the Mexican mill for the first half of July yielded \$14,000 in silver-gold bullion. The bullion was extracted from ores coming from the Consolidated Virginia and Ophir properties. Arrangements are being made for enlarged mining operations at both of these properties.

Luning.—Claims have been staked over a wide area near Benton Springs, nine miles north of here, where there is a new gold excitement following a find made on the surface by Francis O'Boyle of Luning, with whom E. C. Watson of

Luning is interested. O'Boyle and Watson have done much trenching and the showing is sufficient to attract mining men from the surrounding region. Among the men holding ground near the original locations are John Houlahan and Harry Moon of Goldfield and James Houghton and Ad Bachman of Luning. The discovery really was made by a badger, who dug from a hole quartz that was found by O'Boyle. The ore is in a wide vein of quartz in andesite and silicified rhyolite. The vein apparently has a width of about 50 ft., and it has been uncovered for a length of 200 feet.

Pioche.—Production will be resumed by the Black Metals company, according to E. H. Snyder, a director of the company. He says that wages have been reduced 25%; that the individual efficiency of the miner has increased 25%; that the cost of fuel-oil has been lowered 40%, boarding-house supplies 35%, and mine-supplies 20% from the maximum of a year ago. Under these conditions the company should make a substantial profit by shipping its silver-bearing ore.

Rand.—The Nevada Rand Mines Co. recently shipped 15½ tons of ore assaying 3 oz. in gold and 80 oz. in silver. Two shipments of ore assaying \$115 and \$294 per ton, respectively, preceded the last consignment. The high-grade material is being mined from the 180 and 200-ft. level. Lenses of ore assaying \$8000 per ton have been found. J. D. Walker is in charge of operations.

Tonopah.—There are working in the mines and mills of Tonopah 645 men, according to official reports, exclusive of those working for the smaller companies. This appears to indicate that the strikers are losing ground rapidly.

UTAH

Alta.—Owing to surface water at the Louise mine there has been a temporary change in development plans, according to R. O. Dobbs, general manager. A body of shipping ore is exposed in the Maggie raise, and as soon as the water recedes, mining will be undertaken. While waiting an opportunity to mine in the Maggie raise, development will be carried on in the 1200-ft. level.—The Columbus-Rexall company has cut in the No. 8 stope the best body of ore yet discovered. It is said that this showing compares favorably with some of the best ore found in the Cardiff mine, adjoining the Columbus-Rexall.

Big Cottonwood Canyon.—Four teams are now employed by the Woodlawn Mining Co. in transporting silver-lead ore from the mine to the railway spur. It is said that after deducting transportation and smelting charges, there is a margin of \$19 per ton in the shipments made so far this season. An eight-foot bed of ore was recently opened in what is known as the 'West' drift, which gives average returns of \$40 to \$50 per ton.

Eureka.—Shipments of ore from this district for the week ending July 16 totaled 129 cars, of which the Tintic Standard shipped 42; Chief Consolidated, 32; Iron King, 12; Eagle & Blue Bell, 12; Victoria, 10; Dragon, 8; Iron Blossom, 6; Swansea, 2; Mammoth, 2; Gold Chain, 1; Eureka Hill, 1. Shipments the previous week totaled 156 cars.

Soon after August 1 the Tintic Mining Co. will be getting a substantial tonnage of mill-ore from the Swansea property, according to Theodore P. Holt, superintendent for the milling company. The shaft has been re-timber to the 500-ft. level, and that level is now being cleared, after a long period of inactivity. The milling company has been receiving ore from the Horn Silver mine at Frisco, Utah, recently.

The directors of the Little May Mining Co. have decided to equip the property with an up-to-date plant, consisting of a compressor, hoist, pumping machinery, and drills, all to be electrically driven. Recent development work at the property has been encouraging. Several streaks of high-grade ore have been cut, one of which is two feet in width and averages \$140 gold, 24 oz. silver, and 14% copper. Five cars of ore have been shipped.

At the Iron King property, 32 men are now employed. The upper levels of the mine are leased to the American Smelting & Refining Co., and the work there is under the direction of Alfred Frank, the well-known mining engineer of Salt Lake City, with B. H. Grant acting as superintendent. The royalty from ore shipped from this part of the property is for practically all of the development work carried on by the Iron King company for its own account.

The second quarterly report, for 1921, of E. J. Raddatz, general manager for the Tintic Standard Mining Co., indicates a profit of \$4.60 per ton of ore before allowance for taxes and depreciation. The gross value of shipments of 24,566 tons of ore for the quarter was \$812,577.02, or \$33.07 per ton. Smelter deductions and treatment charges were \$14.41 per ton; freight charges, \$4.19 per ton; production cost and development, \$10.01 per ton. Net earnings for the quarter were \$113,179.26, as compared with \$54,444.26 for the three months preceding. The report states that the company's new mill, which has been brought to capacity of 100 tons daily, is treating ores with a head of 15 oz. silver, making a recovery of 81.2% of the silver content, or 11.36 oz. per ton. No mill costs are stated. A new six-room brick assay-office and laboratory was erected and

two large new ventilating fans were installed on the 1200- and 1450-ft. levels, and the foundation for the new large air-compressor was completed. The predominating value of the milling ore being silver, the mill was designed and constructed for the purpose of extracting and saving the highest possible percentage of the silver content in the ore. During May and June the silver extraction was 81.2%.

Park City.—Paul Hunt, superintendent of the Park-Utah mine, reports that the water in the Ontario drain-tunnel is gradually receding. Measurements taken the middle of July show that 25.4 second-feet is flowing from the portal of the tunnel. Work in the Park-Utah is handicapped. When the flow is again normal, mining will be resumed.—Sixty men have been employed in grading, excavating, and doing cement work and carpentering for the new mill to be erected by the Silver King Coalition Mines Co. to replace the one destroyed by fire last January. The first carload of steel for the plant arrived on July 15. Development work in the mine is reported as highly satisfactory; the company now has about 300 men on its payroll. The new milling plant will have a capacity of 450 tons per day, and is expected to be in operation late this year.

The output of ore from mines in this district during the week ending July 16 totaled 1475 tons, as compared with 1267 tons for the preceding week. The Silver King Coalition shipped 767 tons; Judge allied companies, 364 tons; and the Ontario, 344 tons.

Stockton.—The shaft being sunk at the property of the Stockton Standard Mining Co. has reached a point 325 ft. below the collar, at which point the cutting of a station has been started, according to C. F. Buehner, president. Sinking will be continued until the 400-ft. level is reached, when drifting will be undertaken to cut two fissures which lie to the east.

WISCONSIN

Cuba City.—The shutting down of the National Separators has been made complete. The acid-works and magnetic zinc-ore separating department are undergoing repairs, and some of the zinc mines shipping to this plant have shut-down temporarily or until the works resume output.—The unsatisfactory conditions of the zinc-ore market has been responsible for the accumulation of 4000 tons of 60% blende at the National Separators; 3000 tons at the New Diggings separators of the Wisconsin Zinc Co., and 1000 tons at the Enterprise separators at Platteville owned by the Block-House Mining Co.—Crude-zinc concentrate is held in large quantities by the Frontier Mining Co., of Benton, 7500 tons; Rodhams Mining Co., 4000; Zinc Hill Mining Co., 1500; Connecting Link Mining Co., 2000; and Block House Mining Co., 1000.

Mineral Point.—Reduction in the price of zinc oxide, announced by the New Jersey Zinc Co., amounting from 7c. to 1½c. has resulted in stimulating business at the Mineral Point Zinc Works, where from 50,000 to 100,000 tons of zinc oxide is manufactured annually. A single shipment amounted to 20 cars. The freer movement of this stock has encouraged a better feeling in mining circles, since it is apparent that there is more likelihood now of increased operations than a shut-down of the works.

Platteville.—The Zinc Roofing & Products Co., recently organized and incorporated, has established headquarters here. Branches will be established at various points as rapidly as the volume of business warrants. The Illinois Zinc Co. is now making a zinc shingle, which is meeting with favor. Corrugated zinc for roofing is coming into demand. The promoters claim that there is a ready outlet for 100,000 tons of slab zinc annually in products manufactured for building purposes, and that the greatest necessity now to restore the zinc industry is a proper publicity campaign.

WASHINGTON

Valley.—Assays made by Arthur L. Hooper, president of the Admiral Consolidated Mining Co., from an ore-shoot opened recently in the north end of this property, returned \$30 per ton in copper and gold. This demonstrates another source of ore to justify the erection of a concentrator which the company plans to build. The shoot is 4½ ft. wide and in it is a 14-in. streak of carbonate from which the assay was made.

Leadpoint.—Development of lead-silver properties is planned by the Red Top Mountain Mining & Milling Co., incorporated recently with a capitalization of \$100,000.

Northport.—The Blue Ridge Mining Co., whose mines are 14 miles south-east of here, uncovered ore containing silver, lead, and some zinc, at different places for a distance of 1200 ft. along the vein. A tunnel has been driven which cross-cuts the lode at 60 ft.; here the orebody is five feet in width. Assays of shipping ore run 40% lead and 20 oz. silver. Some milling ore also is blocked-out. Thomas Taylor is president of the company.

BOLIVIA

La Paz.—W. Duval Brown, American consul, is authority for the statement that American interests have acquired tin-bearing lands valued at \$2,000,000. The present output is not large but it is expected that it will be increased.

BRITISH COLUMBIA

Alice Arm.—The staff of the Taylor Mining Co. has arrived here for the purpose of re-opening the railway and Dolly Varden mine at once. There is some 3000 tons of ore on the dump that could not be transported to Anyox last year, and this will be shipped as soon as the necessary repairs have been made and the railway is in running order.—The Provincial government is constructing trails in the Illiance River and Upper Kitsault River districts, to open up the country for prospecting.

Greenwood.—It is reported that C. A. Banks is about to re-open the Jewel mine. Banks operated this mine for a considerable time until the rising cost of labor and supplies made it unprofitable. Now that costs have dropped markedly it is thought the mine may be worked profitably again.—An important find has been made in a winze at the Tam O'Shanter mine, at Deadwood camp. The ore shows free gold and silver; a sample assayed \$13.20 in gold and 202 oz. in silver per ton. The property is owned by A. J. Morrison and Dan McGillis.

Nelson.—Justice Murphy has handed down his decision in the case of Insinger v. Cunningham in connection with the Hewitt mine, at Silverton, which Clarence Cunningham operated under lease and bond from Robert Insinger and associates. Insinger is granted the value of the development work that Cunningham undertook, but failed, to do. The plaintiff cannot recover the payment that Cunningham withheld, nor can he recover damages for not being given possession of the mine, but he is entitled to an accounting of the amount of ore mined and shipped. The counter claim for damages on account of not being permitted to operate the property is dismissed.—A narrow vein, assaying \$23.60 in gold, 52 oz. in silver, and 44% in lead has been uncovered in a 45-ft. raise at Silver Reef group, on Anderson creek, about a mile from here. The property is owned by W. J. Richards, W. R. Symonds, and R. Barron, who drove a tunnel 225 ft. and put up the raise entirely themselves during last winter and this spring.—The Van Roi mill, at Silverton, has been re-started.

Trail.—At the annual general meeting of the Le Roi No. 2 mine, held in London on June 23, it was decided to add a Minerals Separation plant to the equipment at the mine.

There is a dump of ore at the mine which is too low grade to ship but from which D. Lay, the manager, estimated \$55,000 can be obtained in the form of concentrate.

ONTARIO

Cobalt.—Mining enterprises in Northern Ontario are benefiting greatly from the adverse rate of exchange as between Canada and the United States. American money is at a premium of 14% in Canada, and this is adding at the rate of more than \$250,000 monthly to the revenue received for the gold and silver produced in Ontario. This amounts to over 40% of the wages paid by the mines.—The price of supplies at Canadian mines is declining rapidly. Machinery, lumber, chemicals, etc., are included in the downward swing in prices. Electrical equipment has declined 25% in many instances, while 40% blasting-powder is now quoted at \$17 per hundred pounds, as compared with \$22 in December last. During June the Nipissing mine produced \$162,824, made up of \$137,264 in silver and \$25,560 in cobalt. The low-grade plant treated 6580 tons and the high-grade plant treated 174 tons of ore.—During the first half of 1921, the Bailey Silver Mines realized \$68,936.77 in gross revenue. The Bailey mine itself shipped 6451 tons of ore during the six months. The company's custom mill treated 4150 tons of ore in June, of which 1060 tons came from the Bailey mine.

Ore has been found at the 9th level of the Kerr Lake mine. Silver occurs in a number of stringers which measure less than one inch in width, the silver content being about 300 oz. per ton. One car containing 45,184 lb. has just been shipped, in which the silver content is 350 oz. per ton.

Porcupine.—There are approximately 2500 men engaged in the operating mines and on assessment work in the Porcupine district. The annual payroll amounts to close to \$4,000,000. Of this total, the Hollinger, Dome, and McIntyre mines employ an aggregate of over 2000 men. In the Kirkland Lake district there are over 500 men engaged at the operating mines, while on small prospects and engaged in doing assessment work the Kirkland Lake total may reach about 800 men. This indicates a payroll of over \$1,000,000. It is clear that the gold-mining industry of Porcupine and Kirkland Lake combined in paying out wages at the rate of about \$5,000,000 per year. Wages are generally high, the present scale being the highest point reached, and with no reduction having so far been made. This is believed to be due to the fact that the advance in wages at the gold mines was slower than in many other industries, and has led to a reduction being deferred.

MEXICO

Calabacillas.—A. H. P. Wynne reports the sale of the San Geronimo mines, owned by the Sierra Mining Co., to American capitalists of Lawrence, Kansas. They intend to begin operations immediately. The properties, which were producers of high-grade ore, will be re-opened by means of a new cross-cut from the present mill, about 300 ft., to strike the Poro workings. Thence it is planned to drift along the contact to intercept the main San Geronimo workings at the 7th level. In running this drift, which will be some 1200 ft. in length, virgin ground will be explored. The plan of J. R. Greenless, president of the new company, is to install a modern mill of capacity to handle 70 tons of ore per 24 hours. Mr. Wynne has been retained by the new operators to supervise the development work.

Mocorito.—The Palmarito mine, a large silver property that has been operating continuously throughout the revolutionary periods, is mined by the glory-hole system. Stamps crush the ore to the necessary fineness, after which it is treated without concentration by cyanide. Plans are now under way to increase the mill capacity in the near future. This property is controlled by capitalists of Philadelphia.

Saltito.—The American Smelting & Refining Co. has acquired possession of the Argentina group of metal mines in the Potrerillos mountains in the municipality of Castanos. The property was recently denounced; the survey includes the Esmeralda mines which were allowed to go by default for non-payment of taxes during the revolution. It produces silver, copper, and zinc. At the start, development work will be done in order to put the mines in shape for production.—The Tres Estados Mining Co. held a board of directors meeting here recently and levied an assessment of 50 centavos per share for the purpose of carrying on the work at its mines in Coahuila.

Zacatecas.—La Luz Mining Co., of San Luis Potosi has

Utah

called for a general meeting of shareholders to take place next August. One of the important matters to be placed before the stockholders will be the discussion and acceptance or rejection of the proposition made by the Cia. Exploradora de Minas de Mexico to take over the mines belonging to La Luz company that are situated in the San Luis Potosi district.—E. Palmer has recently added a number of new properties to his mining interests in the State of Zacatecas by filing on a new group in the Parroquia mountains near here.—Miguel Flores has taken over the Santa Tomas mines in the Sombrerete district and is preparing to sink the old main shaft to a greater depth and extend the other workings.—Several new filings have been made recently on promising prospects in the Mazapil copper district in the mining district of El Oro by native miners. The most promising of these new denouncements are the Buena Suerte and El Porvenir groups.—Some rich cinnabar ore has been discovered near San Miguel by Emilio M. Gaya, a Spanish mining man. The properties are near the old Ascension and Maravillas mines which have produced considerable quicksilver, aside from other valuable metals.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Kirby Thomas is at Toronto.
 E. W. Bradley is at Kellogg, Idaho.
 Albert Burch is on his way to Philadelphia.
 Harold Boyd is in Ecuador for a few months.
 Charles Brackin is in the East for the summer.
 A. W. Harris is returning from Burma to New York.
 Charles Butters has returned to Oakland from Nicaragua.
 Nelson Dickerman has returned from Korea and is now in New York.

Donald D. Smythe is with the Cerro de Pasco Copper Corporation in Peru.

W. L. Penick, sales manager for the Hardinge Company, is in San Francisco.

Walter X. Osborn is with the Rowley Copper Mines Co., at Gila Bend, Arizona.

Louis A. Wright is spending a couple of months in Spain on professional business.

Oscar Lachmund, of Spokane, spent several days in Utah recently on professional work.

C. B. Lakenan has returned to McGill from a trip to Alaska and British Columbia.

Charles F. Rand has been elected to honorary membership in the Iron & Steel Institute, London.

W. Allen Howard, manager of the United States smelter at Midvale, Utah, has been in Nevada recently.

E. R. Ramsey, Western manager of the equipment sales department for the Dorr Company, is in San Francisco.

M. N. Colman, recently at Merced, is now with the California Rand Silver company, at Randsburg, California.

H. R. Bischoff, who has been with the Crown Reserve mine, at Cobalt, Ontario, has moved to St. Paul, Minnesota.

C. N. Schnette has been appointed manager of the Rosebud mine of the Silver Gulch Mining Co., at Dunton, Colorado.

Percy E. Barbour, assistant secretary of the Institute, is receiving congratulations on his recovery from a serious illness.

H. Kenyon Burch, who recently underwent an operation at the Copper Queen hospital at Bisbee, Arizona, is reported to be improving.

Paul Hunt, superintendent for the Park-Utah Mining Co., has returned to Park City after a vacation spent at Redlands, California.

Waldemar F. Dietrich, Associate Professor of Mining in Stanford University, is in Utah, visiting mining and metallurgical districts.

Frank Daniels passed through San Francisco last week on his return to Pasadena, after a month spent in northern California on examination work.

Oliver C. Ralston, of the U. S. Bureau of Mines, has been transferred from the University of Washington, at Seattle, to the University of California, at Berkeley.

H. L. Sulman has been awarded the gold medal of the Consolidated Gold Fields of South Africa at the hands of the Institution of Mining & Metallurgy, London.

L. D. T. Geery, superintendent of the electrolytic department of the Chile Exploration Co., at Chuquicamata, spent a few days at the plant of the New Cornella Copper Co. at Ajo, Arizona.

Frederick H. Morley, of San Francisco, a member of the editorial staff of the 'M. & S. P.' in 1913, was seriously injured by a fall while mountaineering near the Yosemite Valley on July 23.

H. C. Carlisle passed through San Francisco last week on his return from South America, where he spent several months on examinations for the Nevada Wonder Mining Co. His address will be Tonopah, Nevada.

Welton J. Crook has resigned as chief metallurgist to the Pacific Coast Steel Co., to accept an appointment as Associate Professor of Metallurgy in Stanford University. He remains consulting metallurgist to the steel company.

Obituary

John H. Miles, who died at sea aboard the S. S. 'Victoria' on June 30, on his way home at Oroville, in California, from Alaska, was prominent in the history of gold dredging in California, Idaho, and Montana. He is credited with being the first to employ cold water for thawing the frozen gold-bearing gravel of Alaska; for this process he was granted a patent by the U. S. Patent Office and by the Canadian government. He is survived by his wife and one son, Malcolm, both of Oroville.

Edward Dickenson Bullard, senior partner of the firm of E. D. Bullard, died suddenly on July 15, 1921. He was born in Massachusetts in 1854 but was a resident of San Francisco for 25 years prior to his death. His firm was a pioneer dealer on the Pacific Coast in carbide and acetylene gas, and later extended its activities to the supplying of all sorts of apparatus for mine and industrial lighting and safety equipment. He enjoyed excellent health up to the evening of his death, which occurred while he was driving home in his automobile from an entertainment that he had attended with Mrs. Bullard. He is survived by his wife, two sons, and a daughter. In his death San Francisco has lost a respected and useful citizen.

P. J. Kelly, shift-boss at the Highland Boy mine of the Utah Consolidated Mining Co., at Bingham, Utah, and Anton Oleson, a miner, were killed on July 18 on the 1300-ft. level of the mine, where they were caught and crushed by the cage in a manner not definitely determined. Kelly's head was crushed and he is believed to have died instantly, while Oleson was so badly injured internally that he died within a few minutes. No one witnessed the accident. Kelly was 45 years of age and had been with the company for 14 years. He is survived by his widow and two children. Oleson was 26 years of age and unmarried. He fought in the world war and was severely wounded at Chateau Thierry, lying on that battlefield 36 hours before being rescued.

Albert Taylor, manager in the North Atlantic district for the Electric Storage Battery Co., died suddenly on July 6 in New York. He was taken ill in his office and died a few hours later in the hospital. He was born in Liverpool, England, in 1864. In 1884 he was graduated from Princeton university. He served an apprenticeship with the Edison General Electric Co. and in 1885 joined the United States Electric Co. This company was absorbed by the Westinghouse company in 1889 and in the spring of 1890 he became associated with the Stanley Electric Manufacturing Co., remaining in its employ for a period of eight years. In 1898 he entered the employ of the Electric Storage Battery Co. as a salesman. In 1900 he was made assistant manager and in March of the same year was appointed manager of the New York office. When, in February 1920, the growing business of the company made it necessary to divide its territory into five districts, he was selected as manager of the North Atlantic district. His character won him many friends. His ability to put himself in the position of the other man won for him a merited reputation for square dealing. He enjoyed the utmost confidence of all his customers.

THE METAL MARKET

METAL PRICES

San Francisco, July 20

Aluminum-dust, cents per pound.....	05
Antimony, cents per pound.....	6
Copper, electrolytic, cents per pound.....	13.50
Lead, pig, cents per pound.....	1.05—5.65
Platinum, pure, per ounce.....	\$70

Zinc-dust, cents per pound.....	0

EASTERN METAL MARKET

(By wire from New York)

July 25.—Copper is more active but lower. Lead is inactive but firm. Zinc is stagnant but easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 40.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND MARKETS

The United States is practically through the period of violent business disturbance which began in May 1920. We will from time to time have visible evidences of the distressing conditions through which the country has been passing, but these occurrences should be regarded not as indices to forward conditions but as relating to the past. The changes which have taken place have not as yet been recognized by the business public for two main reasons. The period of normal mid-summer dullness now at hand has obscured the certain evidences of improvement and there has been lacking a thorough comprehension of credit conditions, says the market letter of the National Bank of Commerce of New York.

Failure to recognize the passing of the period of insufficient credit has resulted from lack of recognition of the fact that for a long time the credit shortage has been apparent rather than real and due in large part to the unsatisfactory character of some of the risks offered. There is now no bank credit available for operations designed to hold prices at fictitious levels. Orderly organized marketing if fair, succeeds, but attempts to hold prices above the levels determined by international supply and demand are certain eventually to fail. American business and government alike have thus far kept clear of entanglements of this character, but even so, American business cannot avoid their indirect effects. Verticalization schemes providing for indefinite holding for arbitrary prices of such commodities as wool, silk, coffee, sisal, and sugar, would involve the purchase by American consumers of raw materials at levels likely to involve ultimate loss, and as long as these plans contemplate the maintenance of an artificial price they cannot be disregarded in view of credit risks.

Some businesses have found difficulty in getting what they have felt to be a fair line of credit. This has been because of a desire to operate on a basis of inventories of raw materials and goods not yet written down or because in these instances heavy investments have been made to plant and equipment at inflated prices. In such cases they are not yet willing to admit that they will have to take their losses and adjust their operations to make profits on real values only.

Although occasional failure to secure desired credit accommodations has served to keep alive the impression that there is a shortage of bank credit, the truth is that there is now available a volume of credit larger than present business requires. The main requisite for a return toward normal conditions is the will to try for business on a level where it can be had. The period of general liquidation of the raw material markets of the United States has passed. Recent declines are due to conditions of supply and demand in specific lines. This is a normal condition. Wholesale prices of many classes of manufactures have been fully deflated. This is not true in all lines, but recent cuts in the price of steel and widespread reductions in wages indicate that adjustment in wholesale prices will not be long delayed. Retail prices show wide irregularities, and high-cost stocks have been largely disposed of. Price stabilization is, therefore, not far ahead.

Steady betterment of the banking position which has been in progress during the current year gives full assurance against credit stringency when crop-financing requirements become effective.

MONEY AND EXCHANGE

Foreign quotations on July 20 are as follows:

Sterling, dollars:	Cable	3.58
	Demand	3.59
Francs, cents:	Cable	7.80
	Demand	7.82
Lire, cents:	Demand	4.38
Marks, cents		1.32

Eastern Metal Market

New York, July 20.

All of the non-ferrous metal markets are extremely quiet.

Copper is quiet and there is some weakness in prices in the outside market, though leading producers are holding for 13 cents.

Tin is lower in price because of freer offerings, both here and in London, and also on account of the British exchange situation.

Lead is quiet and prices are unchanged.

Zinc prices are easier; there is little demand.

IRON AND STEEL

Cutting of the steel prices announced early in July has been more general in the past week, particularly in plates, structural shapes, reinforcing bars, and sheets. According to 'The Iron Age' the favorable feature has been that more business has arisen. In the eagerness of producers to get a share, prices suffered.

Railroad and construction demand are responsible for most of the week's activity in plates and shapes and the accompanying concessions of \$3 to \$5 per ton in the prices of the two products.

Steel-works operations are on a smaller scale in some districts and in other practically unchanged. The Youngstown district, in particular, is at a low rate.

Aggressive competition between Steel Corporation and independents has been seen in the Chicago market. Pittsburgh basing has gone by the board in that district, and, on a small plate-order from a railroad, 1.80c., Chicago, was done. Presumably lower prices were made on 3000 tons of steel for car-repairs, 2600 tons placed by one fabricating company and 1200 tons by another. The week's transactions in Chicago show that the extent to which the announced prices are cut depends entirely on the size and character of the order and the hunger of the mill.

At Philadelphia a 5000-ton order for plates and shapes for a fabricating company went at 1.75c. for plates and 1.80c. for shapes, whereas both are presumably 2c., Pittsburgh. Several lots of about 1000 tons, reported in the New York market, brought out prices of 1.80c. and 1.85c., and in one case 1.70c.

In concrete-reinforcing bars 1.70c. has been reported for soft steel. A good volume of such bars is under active negotiation, including 3800 tons for export.

Considerably more car-repair work is ahead. The Lehigh Valley's repair and rebuilding program includes 5000 freight-cars and the New York Central will do much both in car and locomotive repair. The Illinois Central is expected to buy 140 locomotives.

Sheets have been sold in the past week at \$3 to \$5 per ton below the so-called stabilized basis. Buying is better and mill operations have increased about 10%.

Eastern Pennsylvanian furnaces have taken the lead in reducing pig-iron prices, reductions of from \$3.50 to \$4 per ton having been made in the past 10 days, the most precipitate drop since the decline began. This has been largely due to keen competition from Buffalo, where very low quotations prevail. In other centres, new concessions of from 50c. to \$1 have been made.

The high duties on manganese ore and ferro-manganese duties in the new tariff bill, having passed the House against the protests of steel producers, a determined effort will now be made by the industry to secure reduction by the Senate.

COPPER

Weakness in copper prices in the outside market was

slightly more pronounced during the past week. Leading producers continue to quote 13c., and apparently are adhering quite firmly to that figure, but the smaller producers at a shade under this price are taking most of the current business, which is small in volume. There are no new features, the whole market being in a decided slump.

TIN

Further weakness in tin prices has been noted during the past week, there being two contributing factors, namely, increased offerings of the metal both here and at London, and the British exchange situation. A small amount of business was done on Tuesday of last week for forward shipment at 28.25c., but during the remainder of the week practically nothing was done. On Monday of this week there was a little more selling for forward delivery at 27.25c. On Tuesday the market was quotable at 27 cents.

LEAD

The American Smelting & Refining Co. is still making the lowest price on lead, 4.40c., New York, and is taking most of the very limited amount of business that is being placed. Some of the other sellers are quoting 4.45 to 4.50c. The outside market has slightly weakened, however.

ZINC

Prices on zinc are lower. Leading producers quote 4.25c., St. Louis, or 4.75c., New York, for July, with an advance of five points for August and another five points for September. On July shipments, however, 4.25c., St. Louis, is being shaded by some of the smaller producers. A slightly better demand for high-grade zinc is reported. Very little business is being placed.

ANTIMONY

Carloads for July shipment are now freely offered at 4.65c., New York, duty paid.

ALUMINUM

The Aluminum Co. of America has reduced its prices, the new quotations being as follows: 99% ingot virgin aluminum, 25c.; 98-99%, 24.50c.; No. 12, 23.80c., and sheets, 39.10c., all f.o.b. shipping point. These prices are still from 2 to 2½c. above the prices on imported aluminum.

ORES

Tungsten Ore: The quotations on tungsten ore are nominally \$3 to \$3.25, but some sellers are asking considerably higher prices.

Ferro-tungsten is available at 42 to 43c. per pound of contained tungsten.

Molybdenum Ore: This ore is quoted at 50 to 60c. per pound of contained sulphide in regular concentrates, usually 85% MoS₂.

Manganese Ore: There is no demand, but manganese ore is held nominally at 22c. per unit.

The total production of portland cement in the United States during the six months ending June 30, 1921, represents about 94% of the quantity made in the corresponding period of 1920 and over 42% of the total production in 1920; the shipments are about 98% of those of the first half of 1920, and nearly 42% of those for the whole year 1920. The stocks, which amounted to more than 11,000,000 bbl., are slightly above normal, comparing with approximately 9,000,000 bbl. on June 30, 1920, and 8,941,046 bbl. on December 31, 1920.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

SULLIVAN DRY-VACUUM PUMPS

The accompanying illustration shows a Sullivan "WA-61" steam-driven, single-acting, dry-vacuum pump. These machines are built in capacities ranging from 300- to 1600-cu. ft. displacement per minute. The intending purchaser of a vacuum pump within these limits will find that the Sullivan machines embody numerous features of design and construction which secure economy of power, continuous operation, and high efficiency.

One of the leading features of this class of pumps, which makes for efficient operation, is the use of the Sullivan improved wafer-plate valves. These wafer valves are compact, low in lift, and very light in weight. They are practically indestructible, and require no regrinding or other attention. They are noiseless in operation and are so light

Sullivan Dry-Vacuum Pump With Single Steam- and Vacuum-Cylinders

that they will function under the exceedingly small pressures developed in vacuum service, enabling these pumps to create and maintain an unusually high degree of vacuum (within one-half inch of the barometer reading on a closed suction).

These pumps are adapted for any dry-vacuum service within their capacity range. They are substantially built, and the amount of metal and area of bearing surfaces which will be found in the principal working parts, such as crank-pins, shaft, connecting-rods, etc., are unusually liberal and insure stable dependable operation. All working parts are fully enclosed and are splash lubricated, so that wear and repair are reduced to a minimum.

Sullivan vacuum pumps are built upon the interchangeable part system, thus securing the advantages of production in quantities. As is the case with Sullivan air-compressors, including the simplest as well as those intended for the highest duty, the materials for these pumps are carefully selected for their respective purposes; accurate painstaking workmanship, rigid inspection, and thoroughgoing tests both during manufacture and after completion are guarantees of

satisfactory and long service in the customer's engine room.

The equipment for the "WG-61" vacuum pump includes: one sight-feed lubricator for the vacuum cylinder; one complete set of drain cocks; one set of wrenches for removal or adjustment of the various parts of the machine; one set of packing for the piston rod; foundation blueprint and instructions. In addition to its line of single-acting steam, the company manufactures belt-driven pumps and duplex pumps of larger capacity but of this same class.

NEW COMBINATION BALL-MILL FEEDER

The Hardinge Company has recently designed a combination drum- and scoop-type feeder for ball- and tube-mills. The largest size has a capacity-rating of 2000 tons of dry ore per 24 hours. This will enable the feeder to take a large initial feed in addition to a large circulating load. The drum of the larger feeder is 48 in. diam. and allowance is provided for a scoop with a radius of 48 to 54 in., as may be required by the customer. Aside from its large capacity all parts of the feeder are reversible. This means that the purchaser no longer has to specify which way his mill is rotating when buying a feeder. It also enables him to reduce his stock when he has mills operating in both directions, as by merely changing the parts the same feeder can be used on a mill rotating in clockwise or counter-clockwise direction. Parts are made replaceable to take care of ordinary wear and as a consequence, the cost of renewing parts is small. The advantages of a combination feeder are, in general, well known, but for those who have not used them, a word as to their operation will be of interest.

The initial feed is fed by a chute to the opening in the drum, this initial feed being coarse material, which, if dropped into a box and picked up by a scoop, causes undue wear on the scoop-lip and sometimes, when extra large pieces drop in the box, might break the box or the feeder itself. The over-size is returned from the classifier at a lower level; accordingly means must be provided to lift it up and into the drum. This is taken care of by a scoop on the outside of the drum which operates in the ordinary feed-box but has no large material to handle, as none is dropped into this box and therefore the wear is greatly reduced and there is no danger of breakage to the box. Such feeders as this have been used for a number of years on the large mills handling in excess of 500 tons per 24 hours and have proved to be practical, as the wear is light and they cause no mechanical trouble.

A NEW FLOTATION REAGENT

In all the writings on the flotation of ores it has always been the contention of the writers that a colloidal element could never be used in the flotation of minerals, or as a substitute for oil, and that any colloid was fatal to flotation. Royer Luckenbach, of Brooklyn, N. Y., the inventor of this reagent, claims to have proved by commercial tests that their contentions are entirely erroneous.

In the oil-flotation process, as is well-known, the oil has

to be beaten into the pulp, by violent agitation, in mixers before it is in a minutely sub-divided condition to reach the particles of mineral in the pulp; whereas, in this new process, the great advantage of using an easily emulsifiable element, that instantly breaks up in the body of the pulp into a minute colloidal sub-division, and instantly attaches itself to every particle of mineral without any pre-mixing is a radical improvement, both as a time element and greater thoroughness in operation, producing an extremely clean high-grade concentrate in the first cell, together with a high recovery. Extractions on difficult ores have been made by the Rex reagent as high as 98.9% with a 48% concentrate.

This reagent [which is a pine-pitch in alkaline solution] forms a very close-grained viscous froth of great volume and power, being a frother and selector combined; whereas, in oils the good frothers are poor selectors and good selectors are poor frothers, necessitating the use of a good frothing-oil with a good selector, the usual combination being coal-tar and creosote as selectors, with pine-oil as a frother, which latter has so greatly increased in price as to be almost prohibitive.

The Rex reagent is inexpensive, and its economical use is still further reduced by the re-use of the pulp-water, which retains its powerful frothing and selecting qualities to a marked degree for numerous re-uses of it with but a little addition of the original reagent, as needed.

The reagent can be used either in an alkaline, acid, or neutral circuit. The process is entirely chemical and is at all times under perfect control of the operator, whereas, the oil process is entirely mechanical. This chemical control permits of preferential flotation, as the separation of zinc from lead, pyrite and pyrrhotite from chalcopyrite, and numerous combinations can be made with it and other chemicals to meet the conditions in ores. It will extract copper carbonate without sulphidizing—also lead carbonate and all sulphides, including metallic copper and silver, and is particularly good on gold sulphides, producing an extremely clean concentrate in the first cell, that can be cyanided if desired, which by oil it is impossible to do, as the oil interferes with the solvent action of the cyanide.

The cost will average eight cents per ton. No changes are necessary in any mill now using oil to replace it with this reagent, which is practically a universal reagent, and is adaptable for use on all ores with but little change, and, being a powerful selector and frother, all in one, its value in that respect will be greatly appreciated in the flotation of ores. The mining industry will welcome its valuable feature of iron elimination in ores, which oil has failed to overcome, as it sweeps away the only serious obstacle to the full development of many valuable but low-grade mines, long neglected in both the precious and baser minerals in this and other countries.

As an instance of what has been done, the Canadian government at Ottawa made exhaustive tests on a full commercial scale in 1920 on ores high in iron pyrite and pyrrhotite containing 3% chalcopyrite; an extraction was made of 94% with complete elimination of the iron. Demonstrations of this process are given at the Luckenbach laboratories, at 105 Liberty St., Brooklyn, New York.

COMMERCIAL PARAGRAPHS

Offices have been opened at 236 Mills building, San Francisco, by the Mine & Smelter Supply Co. M. H. Carpenter is the representative in charge.

It is announced that the Dominion Oxygen Co., Ltd., will break ground for a new quarter-of-a-million-dollar oxygen plant at Montreal, which will double the company's present capacity. The building will be 100 by 100 ft., and will be substantially a duplicate of the company's Toronto plant.

The San Francisco office of the Pawling & Harnischfeger

Co., of Milwaukee, has been moved from the Monadnock building to 32 Beale street. At this new address the company maintains a complete service-station, warehouse, and display room for cranes and hoists, machine tools, and excavating machinery. R. M. Taylor, district manager for the Pacific Coast, has his headquarters now at the Beale street address. J. MacFerran Taylor is a new member of the Pacific Coast sales district.

E. W. Bullard, junior partner of the firm of E. D. Bullard, San Francisco, has accepted the invitation of the U. S. Bureau of Mines to be one of the judges at the International First-Aid and Mine-Rescue Contest to be held September 1, 2, and 3 at St. Louis. Mr. Bullard will leave San Francisco the early part of August for the East, where he will spend a month visiting the large mines and metallurgical plants to study their safety and welfare work.

A catalogue presenting its full line of packings, gaskets, and pump-valves is one of the important recent publications of the United States Rubber Co. Fully illustrated, it departs from the usual form of such catalogues and is filled with definite information regarding each item listed and the specific uses for which it is best fitted. To assist in the selection of 'the right packing for the right place', a classified index of the various styles of packing sets forth the packings which are recommended for the different conditions of service. The drawings show the details of construction with such clearness that the adaptability of any style of packing may easily be judged.

The Du Pont Company has developed and perfected a formula for the manufacture of a straight dynamite that is proof against freezing even in zero temperatures. As a consequence of this development, the company has determined to discontinue the manufacture of its former straight dynamite and hereafter all this kind of explosive will be 'low-freezing'. The perfection of the formula is the result of years of experimentation in the laboratory and in the field and marks one of the greatest advances in the art of explosives manufacture. Straight dynamite has for years been the standard of the world in nearly every kind of open work, but a disadvantage has been its liability to freeze at temperatures below 50°F. As any dynamite loses some of its efficiency when chilled or frozen, many attempts have been made to make it low-freezing. The perfection of the new formula by the Du Pont Company makes it possible to use straight dynamite the year round in industrial operations. Thawing, with its loss of time and attendant dangers, has practically been eliminated.

To meet the severe requirements found in steel-mills for driving mill-tables, screw-downs, tilting tables, and other machinery, a line of unusually rugged direct-current mill-type motors has been developed by the General Electric Co. A complete description of these motors is given in Bulletin No. 48121.1A, entitled 'Direct Current Mill Type Motors, Type MD and MDS'. Some of their chief characteristics are listed in the bulletin as follows: Heavy mechanical construction throughout, large foundation area, heavy integral counter-shaft brackets, ease of replacing parts, ease of making repairs, small stored energy in the armature, superior commutation, heat-resisting insulation, and moving parts totally enclosed in the MD type. These motors are primarily designed for driving steel-mill auxiliaries, but they are also adapted to such applications as heavy-duty cranes, coal- and ore-bridges, unloaders, charging machines of all types, coke pushers, levelers, electric shovels, electric dredges, gates, valves, and small heavy-duty hoists. The bulletin points out that MDS motors differ from MD motors in having their upper half entirely open. A detailed description of all parts is given, tables of ratings, a key photograph and list of parts, as well as a number of photographs of actual installations on various types of mill and other machinery.

T. A. RICKARD, . . . Editor

PRESIDENT HARDING'S public utterances recently have been much to the point. In a message to the special Fourth of July number of 'The Times' he emphasized the fact that a clearer understanding between the two great English-speaking nations "will prove the surest antidote to that unfortunate irritation which is too often caused by the actually unimportant but sometimes aggravating utterances of thoughtless demagogues and irresponsible agitators". Hearst papers please copy.

ON another page will be found a short article, describing an unusual copper-lead prospect, by Mr. W. L. Uglow, who is Professor of Mineralogy and Petrography in the University of British Columbia. Many of our readers will recall the fact that, in 1914, when Mr. Uglow was on the Geological Survey of Wisconsin, he was deputed to study the valuation and assessment of the zinc mines of Wisconsin for the State, and prepared a report that is one of the standard publications on mine appraisal. We welcome him to our columns.

COPPER continues to be quoted at a low price, but conditions are improving. We note that the Copper Export Association has called \$1,000,000 of its 8% bonds for payment, at 101 and interest, on August 15. These bonds are of the series maturing on February 15 next year. The other bonds are quoted at par or slightly better. It is estimated that total sales for export during the first half of the current year have amounted to 115 million pounds, whereas our domestic production is now only 40 million pounds per month. Germany has been buying copper in increasing quantities.

ONE of the unexpected consequences of the Great War is the shifting of the world's coal trade from England to the United States and other countries. Before 1914 the English collieries distributed 80 million tons of bunker coal to foreign ports, this trade representing 75% of the British exports. Last year the coal exported amounted to only 24 million tons. In October last the price of coal to the British railroads was 42 shillings per ton, as against 17 shillings before the War. "To bring a ton of coal to the pit-head," says Mr. C. W. Barron, "costs on an average 31½ shillings in Great Britain and 13 shillings in the United States." The higher cost is due to inefficient methods, the loss of so many of the best miners in the War, and the depth of the

mines. Mr. Barron ends the article, in the 'Boston News Bureau', from which we have quoted, with the following statement: "The United States is the supreme power; not because it has the major part of the world's available gold; not because its national debt is less; not because of its wheat-fields, its cotton or its pork production; but because it has an equipped capacity to output for many generations 600 million tons of coal per annum and because more than two-thirds of the world's oil output is now American-owned".

IN this issue we publish an interesting review of metal mining in California during the current year. It is written by Mr. Charles G. Yale, of the U. S. Geological Survey, and therefore is amply authoritative. This review was written two months ago and has had to go to Washington, hence it is slightly out of date already in one or two details. For example, "the two most productive deep mines of the State" were shut-down late in June, as anticipated by Mr. Yale, but they have already resumed operation, we are glad to say. The reference is to the North Star and Empire mines at Grass Valley. Our own information is entirely in accord with that of Mr. Yale in regard to the expanding interest in gold mining in California.

AMMUNITION for the optimists, who are engaged in dispelling the gloom that prevails among their mining friends, may be found in the dividend for July recently declared by the Homestake Mining Company, of South Dakota. This is the third successive monthly dividend, since May, the last disbursement previous to that time having been made in September 1919. Some folks, with pessimistic perversity, argue that gold mining thrives most when times are dullest, and that the revival of prosperity for gold producers like the Homestake company is direct evidence that we are at the threshold of a period of greater depression as regards business in general. To them we venture to point out that it is the process of financial deflation that is painful, *not* the state of affairs that results when that process is finished. May not the revival of gold mining reasonably be interpreted as indicating the completion of this disagreeable, but apparently unavoidable, and manifestly desirable, deflation? We note that the Homestake company is now producing at maximum capacity and that the output for the current year is likely to exceed that of

1920 by \$1,500,000. The Homestake is in many respects the greatest gold mine in the world. The ore averages only about \$3.50 per ton; operations have been conducted continuously since 1878, during which time the production has exceeded \$165,000,000, yet the prospect for the future is bright. Those who control the company have the habit of saying little regarding their enterprise; but the shipments of bullion to the mint, amounting regularly to about \$6,000,000 per year, speak for them. The same may be said of the dividends, which, including that for July 1921, total \$42,115,929.

Taxation of Mines

The temporary idleness of many mines is making trouble for, among others, the tax-collector. In Shasta county, California, for example, the representatives of the Mountain Copper, United States Smelting, and Balaklala companies have appeared before the Board of Supervisors to protest against excessive taxation. The County Assessor bases his levy on the cash-value of mining property, but what is the cash-value of a mine when the 'ore' in it cannot be exploited at a profit? For example, the Iron Mountain mine was valued, for taxation, at \$549,000, whereas Mr. Albert Burch, as consulting engineer to the owners, the Mountain Copper Company, testified before the Board of Supervisors as follows: "Under circumstances as they exist today, I could not advise a client to buy the property at any price, because no money can be made out of it, but speculatively it might have a value perhaps of as much as \$100,000." The reserve of 'ore', that is, of copper-bearing rock that under favorable conditions was labeled 'ore', is estimated at 260,000 tons, in the form of small lenticular masses averaging 2.38% copper. No gold or silver is associated with the copper. The manager, Mr. William Kett, testified that formerly the operating profit on this material was 80 cents per ton, but today the mining and treatment of it would involve a loss of \$1.06 per ton; and this loss would not include overhead charges, depreciation, or general expense. If "former economic conditions were to return" the fair sale-value would be, say, \$225,000, according to the evidence given. The return of such conditions, as of 1913, is suppositions. The question then arises: "Why should the value of a mine at a future date be made the basis of a valuation today?" The Assessor, it seems to us, is not justified in appraising the property upon an expectancy for which he can give no technical or moral justification. We feel sorry for him, presuming that he desires to be just, because he has to square his good intentions with the need for raising revenue, but we sympathize cordially with the officials of the mining companies in the protest against the attempt to shift the burden of county finance upon them. An idle mine, so long as it is idle, is of no immediate value; its speculative value will depend upon the anticipation of a resumption of profitable activity; while it is idle it is not a profitable asset and it should not be appraised as such by the Assessor. He, in behalf of the County, should take his

share of the unpleasantness caused by adverse conditions, which are temporary, retaining the right to raise the valuation as and when the profitable operation of the mines is resumed. It looks as if the Assessor were trying to save the County from the effect of untoward industrial conditions by 'passing the buck' to the mining companies.

The Tariff Again

The Bill now before Congress has been stultified by the clause imposing an import duty on mineral oil. The inclusion of this proviso throws light on the mental dishonesty of the proposed legislation. In the first place, we have been told by various authorities, including the former Director of the Bureau of Mines and the present Director of the Geological Survey, that our oil resources are in danger of depletion and that therefore we ought to encourage "the participation of American citizens in the development of oil resources in many foreign lands". Good; therefore we ought not to export our oil to other countries; on the contrary, we ought to encourage the importation of foreign oil to us, thereby conserving our own resources and aiding our citizens, as in Mexico, in producing oil for shipment to our domestic market. Manifestly, an export duty is logical; whereas an import duty is the negation of common sense. Yet, even after the President, wisely and courageously, had urged the excision of the duty on oil, no less than 86 Representatives voted for it. The avowed principle on which the new tariff is constructed is protection, not revenue. The duties on oil, cement, lime, glass, aluminium, asphalt, steel, and hemp indicate the subordination of economics to log-rolling and political obligations; for much of the tariff represents the payment of the debt owed to those who gave financial support to the Republican party in the last election. Moreover the proposed plan for a valuation of imports based upon the price of similar products on the American market, instead of being based upon their cost to the importer, is a further and most effective check to international business, for it will have the effect in many cases of doubling the duty. Such *ad valorem* rates are open to unfair and arbitrary interpretation; they introduce a variable factor likely to injure the consumer no less than the producer. This feature of the new tariff illustrates again the subordination of wise statesmanship to parochial politics. The rates proposed under the new tariff are about the same as those levied under the Payne-Aldrich law; thus they disregard entirely the change in conditions caused by the War. By reason of that change the United States has ceased to be a debtor nation, and is now the great creditor nation of the world. Before the War the effect of a protective tariff on our export trade was negligible; now the two are so closely related that one may kill the other. Before the War about six billion dollars of European capital was invested in the United States, requiring therefore an annual remittance of about \$200,000,000. If to this we add the expenditures of American tourists, freight, insurance, and other items, the total sum remitted abroad

annually was about half a billion dollars. That is one reason, among others, why our average excess of exports over imports between 1911 and 1914 was a little more than half a billion dollars. The War has reversed the position; we have loaned ten billion dollars to Europe, we have bought the American stocks and bonds that had been marketed abroad, and we are now entitled to receive rather more than \$500,000,000 per annum. It cannot be paid in bullion; it can be paid only in commodities. Obviously the ideal arrangement is for the Europeans to send us what we do not produce, or produce less well than they do, and for us to send them what we produce, or produce better than they do. In short, as between creditor and debtor, it is desirable to trade in non-competitive products. This is not a time to incubate and coddle non-essential industries to the detriment of our commerce. Owing to the stimulus of the War we have been producing a surplus of certain commodities, including the metals; the export trade plays a large part in fixing the domestic price of such products; if our mining industry is to prosper we must find markets abroad, and that we shall be able to do only if we allow the importation of other products, chiefly manufactured materials. The so-called Latin-American countries can buy many things we produce, more particularly our manufactures, but they are producers of the metals, so that we cannot expect to sell them our surplus. The market for our excess production of metals is in Europe.

More Uses of Copper

Recently, apropos of the consumption of copper, we discussed sundry aspects of the electrical industry, particularly the impending expansion in the building of large interlocking systems of transmission and the further electrification of existing railroads. Rapid progress in both directions is assured. We understand that the Southern Pacific Company would electrify its Shasta division at once if it were practicable to finance the undertaking at the present time. In fact, the unfavorable status of the money market is the obstacle that postpones work on a number of large projects; there is no doubt from the engineering standpoint that the work will be done, and consequently that the required copper will be used. The copper miner cannot, nor need he, take any aggressive steps to stimulate the demand for his product for this purpose. There are, however, sundry industries in which copper was formerly an extremely important raw material but in which the use of inferior substitutes has lately become widespread. Among these may be named automobile manufacturing and the building industry; the latter requires metallic material for roofing, cornices, and plumbing and other interior fixtures. No well-informed person questions the superiority of copper and brass for a great many of the uses for which substitutes are now being employed; the manufacturers of automobiles know this and the architects and builders know it. What then are the reasons that prevent copper from regaining its former position? Dur-

ing the War it was difficult to obtain the metal for many purposes because of the rulings of the War Industries Board, which scrutinized closely every order that did not come from a Government department; moreover, the price of the raw material was high. Today, with a large surplus of refined copper selling at less than 13 cents per pound, the consumption in the industries mentioned is sadly disappointing to the producers. Mr. Ford used only 20 pounds of copper in his 1920 models; the average for all other automobiles was about 30 pounds. Manufacturers of some of the higher-grade machines used as much as 200 pounds of copper, including the copper content of the brass; and this feature of their construction is said to add much to the durability and reliability of the cars. It is safe to say that the cost of brass, as compared with that of the substitute metals, is the only factor that prevents its more general use in automobile manufacture. Although the same condition applies to the building industry, another factor enters into the problem, namely, the sentiment of the general public. If the producers of copper desire to increase the consumption of their metal in the building industry they must do two things: first, they must see that the copper and brass in the semi-manufactured form, that is, as sheets, plates, rods, and tubes, are obtainable at a cost proportionate to the market price of ingot copper; and, second, they must see that the public is impressed with the ultimate economy of using copper and brass, even though the first cost be slightly greater. It is, of course, out of the question for these materials to compete with inferior substitutes on the basis of first cost to the consumer.

It is difficult to justify the price asked for copper sheets, tubes, and similar products by dealers, even when the abnormal cost of fuel and labor required for the fabricating is given due consideration. Why should the wholesale cost to the user of a copper tube containing two pounds of copper be \$1.80 whereas a steel tube of similar size and shape costs only 40 cents, when the difference in the value of the raw materials is not more than 25 cents? These figures are merely illustrative of a condition that actually exists today; they indicate that, somewhere between the refiner who produces the copper ingots and the dealer who sells to the consumer, an unwarranted profit is 'absorbed' by someone. From the standpoint of the miner and of the man who is building a house it matters little who gets the money. The first step for the copper producer seems to be some action that will put his product in fabricated form on the market at a reasonable price. Stating the case plainly, two courses are open to him: he must convince the present manufacturers and distributors that it is to their interest to co-operate in selling more copper, or he must do his own fabricating and his own distributing so that the consumer may get a square deal. Possibly the fabricators still have on hand products made of copper that was purchased at a war price; if so, the sooner they charge the difference to loss the sooner will copper commence to move. If they cannot be persuaded to do this, the only alternative seems to be for the producers to enter the field in competition. There are

objections to such a course, but they may easily be outweighed.

The second move for the producers is to educate the public by generous doses of propaganda; most of us have had so many kinds of this medicine that a little more can do us no harm. The man who is erecting a warehouse, an office-building, or a home, must be shown that he will save money in the end if he uses brass and copper instead of iron or steel or glass or far or whatever the inferior substitute may be, even if the first cost be greater. If the architects and contractors appreciate the ultimate economy of the more costly material, why do they not exert themselves to guide their clients in the selection of copper products? The answer is that they have no incentive. The architect may make two estimates, one specifying copper or brass and the other some cheaper alternative material; the choice is made by the client, who generally has no definite knowledge of the comparative life of the two materials, and quite excusably selects the one that has the lower first cost. The man most interested in enlightening the public, the ultimate consumer, as to the superiority of copper and brass is the producer of copper. If he does not disseminate knowledge of the virtues of his product no one will. Evidently therefore the remedy for the present apathy toward copper, that exists among those who build, can be expressed in one word; advertise! As already pointed out, advertising is not required among makers of automobiles; they already know its merits. But both the automobile manufacturer and the builder need fabricated copper at a price that is in reasonable proportion to the cost of producing the raw material. We know that many of the producers of copper are fully alive to these conditions; we know that they have discussed these questions from every angle; but we are still waiting, we confess, with growing impatience, for some action on their part. The building industry has been in the doldrums for several years; it is certain to revive and to flourish with unprecedented vigor within the next year. Now is the time for the copper miner to do his missionary work. Europe will require copper; electrification of railways will require copper at home; other domestic industries will require copper; but the building industry is one that requires it now! It looks as though the copper producers needed an alarm-clock.

Indexing Current Technical Literature

In 1881, the late Professor J. B. Johnson, of Washington University, St. Louis, commenced the indexing of the material appearing in a few of the many publications devoted to engineering. These included the 'Engineering News', 'Van Nostrand's Engineering Magazine', the 'Journal of the Franklin Institute', the transactions of the American Society of Civil Engineers, of the American Society of Mechanical Engineers, and of the American Institute of Mining Engineers, together with the British publications, 'The Engineer', 'Engineering', and the proceedings of the Institution of Civil

Engineers. This index appeared in the 'Journal' of the Association of Engineering Societies. In 1892 the first volume was published in book form, with the title of 'Engineering Index'. In the meantime the 'Engineering Magazine', a monthly publication, had been producing an index of a similar character. Amalgamation followed. The second issue of the 'Engineering Index' was published in 1896, under the editorship of Professor Johnson; subsequent volumes appeared until the close of 1918, two of which covered periods of five years each, the remainder appearing annually. Professor Johnson's efforts marked the initiation of the first serious attempt to classify periodical literature relating to engineering; the publication of each successive volume showed an increased scope. The 'Engineering Index' served its purpose during a period when specialization had not reached the stage in which one finds it today; thus, in 1906, the 'Index' contained only about 50 pages devoted to mining and non-ferrous metallurgy, out of a total of about 400. The book, however, was carefully prepared and edited; and credit is due to the sponsor of the work, Professor Johnson, and to the publisher, Mr. John R. Dunlap, for their enterprise. In 1918 the venture was absorbed by the American Society of Mechanical Engineers, which has since issued two volumes, for 1919 and for 1920, the second having come to hand this week. In these an attempt has been made, as formerly, to include mining and metallurgy, but with indifferent success; the principal cause for the failure of the book that lies before us is the fact that the compilation and classification of articles has been undertaken by one who is unfamiliar with these particular arts. For example, under 'Cyaniding' are indexed four articles only, three of which refer to the manufacture of cyanide, and the fourth to a paper on experiments to determine the delicacy of tests indicating the presence of minute amounts of cyanide. The book cannot be accepted as of real value to the mining and metallurgical professions; this is not strange, for it has been compiled by officials of the Society of Mechanical Engineers, who cannot be expected to appreciate the details of mining and metallurgy. It also contains much material in which we are not interested; our subjects require special treatment.

Early in 1911, the 'Mining & Engineering World', a weekly technical periodical published at Chicago, introduced an important innovation: a classified collection of references to current literature on subjects confined to mining, metallurgy, and allied topics. The index appeared in each issue, and constituted a useful addition to an otherwise feeble magazine; this was the first attempt to supply a long-felt want, and it was decided to publish the references in book form at semi-monthly intervals. Thus a hand reference book of current technology, from foreign as well as from domestic periodicals, was produced. Essential details were given, and in some cases a brief summary of the article was included. An index of subjects was supplemented by an index of authors—a feature that was (and is still) absent from the 'Engineering Index'. This added to the value of the

book. The task was performed by those who were evidently conversant with mining and metallurgical work in general; and a measure of success resulted. Unfortunately, however, the 'Mining & Engineering World' was absorbed by the 'Engineering & Mining Journal' in 1917, and its period of usefulness in this particular connection was brought to a close. The index ceased to be compiled, or to be published in book form, but the volumes already issued remain a source of information for the period 1911 to 1917; they constitute a monument to the only real attempt that has been made to index the current literature of mining and metallurgy, and to publish the information in book form. The 'Engineering & Mining Journal', for some years previous to the absorption of the 'Mining & Engineering World', had included in its pages, at monthly intervals, a mining index, but it was incomplete and poorly classified, and was evidently arranged by one who was not himself conversant with operations and processes. It failed to serve its purpose, and ceased to exist last year.

Among other attempts to classify current technical literature are the 'Index of Recent Papers', published in the monthly bulletins of the Institution of Mining & Metallurgy, of London, and the 'Mining & Metallurgical Index', published in the monthly magazine of the American Institute of Mining & Metallurgical Engineers. Both of these are confined to mining, metallurgy, and allied subjects. The index of the Institution is thorough, carefully prepared, but restricted in scope; that of the Institute is more ambitious, as far as quantity is concerned; it is stated that no less than 1300 papers and periodicals are consulted, but it contains no index of authors, and is not published in book form. In 1909, Dr. W. L. Crane brought out the 'Index of Mining & Engineering Literature'; this represented articles that had appeared in 18 publications. The entries contained no summary of contents of the contributions in question—a feature that is also absent from the index prepared by the Institute—so that, as a means of finding what was wanted, the book left much to be desired. It was not well edited, and contained no index of authors. The number of publications examined was small. Here we may remark that in many cases the title gives no clue as to the information to be conveyed by the author. The selection of apt and illustrative titles for contributions to technical literature is an art in itself. The great majority of authors have no idea of the importance of correct headings; few editors have either the time or the ability to find a satisfactory substitute for an ill-chosen title. Thus it is that matter of vital interest is indexed improperly, and is therefore inaccessible to the reading public. A second edition of Dr. Crane's book appeared in 1912; but the work failed to meet the demands of the profession and publication was discontinued. One of the best examples of abstracting work is shown in those pages of 'The Mining Magazine', of London, that were headed 'Précis of Technology' and are now named, less aptly, 'The Mining Digest'. However, this effort in no way represents a complete summary of current tech-

nical literature on so extensive a subject as mining and metallurgy; and although the abstracts form a valuable and interesting adjunct to the 'Magazine', they fail to function as a comprehensive index. From the foregoing it must be realized that there is an immense amount of duplicated effort in mining and metallurgical research and commercial operation, because of the difficulty that our technical men experience in keeping abreast of present practice or past achievement. We need, not only a complete index of titles, subjects, and authors, but a brief résumé of each contribution. Professionally speaking, we are in the backwoods, because of lack of scientific guidance and because of a failure to appreciate the fact that our methods are archaic. In the Engineering Societies Building, in New York, two staffs of separate engineering societies are engaged in an attempt to index the current literature relating to mining and metallurgy; the results are published separately; and both fail to meet requirements. If one quarter of the clerical labor that is involved could be placed under the direction of capable editors, and if specialists in the profession were to come forward with their aid as abstractors, we should have an index of current literature that would be of immense value in stimulating research, in preventing the overlapping of effort, and in directing attention to the vast amount of excellent material that appears in the technical press and in the transactions of domestic and foreign engineering societies, much of which is inaccessible because of faulty titles, improper indexing, and unsatisfactory classification.

At this stage of the discussion it is pertinent to observe that successful indexing and abstracting involve a high degree of analytical and literary skill, coupled with a specialized knowledge of the subject discussed by the author. It would be impossible to find any one individual who combined the qualifications, and who could perform such a task successfully; but by co-operation between the editor and the specialist it has been proved by our confrères, the chemists, that the work, if properly standardized and controlled, can be done well. The achievements of the American Chemical Society in this connection are noteworthy; its comprehensive and well-edited publications prevent duplicated research, and provide the members of the profession with all the information they need with regard to their own specialties as well as with reference to allied subjects. In metallurgy and electro-chemistry we turn often to the Chemical Society's publications for careful and instructive abstracts of all current literature on these subjects. The editorial activities of the Society are worthy of imitation. The monthly 'Journal' is a serious publication of original matter, in which there are no advertisements. Those in charge appreciate the fundamental principles of successful literary work; this is indicated by the fact that intending contributors are advised that 'Papers should be submitted ready for publication, and in typewritten form. In preparing them the authors are requested to observe the utmost brevity consistent with clarity of presentation'. The staff includes

an editor and 12 associate editors. But the Society's publication to which we wish to draw especial attention is 'Chemical Abstracts'; it is issued twice a month, and is of such a size and character as to suggest satisfactory binding in book form. Each semi-monthly issue is complete, with an index of authors. Attention is given to articles, books, patents, and to any mention of chemical or allied work. All details are recorded, followed by a brief abstract, which is well edited; the initials of the abstractor, whose full name appears in the honor roll on the front page, are appended. To carry this work to a successful conclusion there is one editor, who is assisted by 2 associate editors, 45 assistant editors, and about 250 abstractors. These figures indicate the direction in which the American Chemical Society prefers to expand its activities; it also shows that such work cannot be accomplished without the expenditure of a large amount of labor, aided by special technical knowledge. The result is that chemists and chemical engineers are supplied twice a month with a condensed account of every mention of each phase of technical endeavor in all parts of the world. This is of incalculable value to the industry, as well as to every member of the profession of chemistry. 'Chemical Abstracts' is also useful to the metallurgical engineer, for the activities of the chemist and the engineer overlap to such an extent that many details are of interest to both. The Society of Chemical Industry, through its 'Journal', has also done much toward indicating how abstracting and reviewing of technical literature should be done. In the chemical industry there has been keen competition between the two leading technical societies, and this has led to the attainment of a high degree of efficiency in publication work.

It is time that we of the mining and metallurgical profession insisted upon the abolition of that waste which marks the ineffectual efforts of the many to produce a satisfactory index and résumé of the current technical literature in which we are interested. The work that will be involved, as soon as we realize the necessity and the importance of the task, will be considerable; several hundred volunteers—each a specialist in a particular branch of mining or metallurgy, some of whom must be able to read a foreign language—are needed for the work of abstracting. If the chemists can find such men among their ranks, surely we can do likewise. The abstracts must be edited to conform to a standard style of diction, spelling, and abbreviation; they must be indexed, not only by title but by substance; and they must be prepared for frequent publication and in a manner that suggests preservation in book form, suitable for conservation as a permanent record. Such a magazine should not compete in any way with the technical press; the size of the page would make it too small for general advertising. A list of editors and abstractors would appear on the front page. In all such details we cannot do better than to copy closely the procedure adopted by the American Chemical Society. Our ranks contains the names of men who are second to none in technology and science. Hundreds of these should be willing to help forward such a

scheme by a little work, which would at the same time put them into closer touch with their own special subjects. It is evident that the issuance of such an indexed précis of technology should be in the hands of the national society, in this case the American Institute of Mining & Metallurgical Engineers; if properly edited and arranged it should prove of infinitely greater value to the profession than the present monthly magazine, 'Mining & Metallurgy'. We hesitate, however, to make a suggestion of this kind, because it would call for more workers and fewer committee members, as well as special editorial and clerical staffs. The expansion of the Institute during recent years indicates a commercial growth. The new departure could doubtless be made financially successful, for a fortnightly publication of such a nature would be exceedingly valuable to every mining and metallurgical engineer, but its primary purpose would be to stimulate research and initiative, to prevent the overlapping of scientific and technical work, and to encourage an interest in the writings and achievements of others. The enumeration of these ideals will doubtless raise a smile in the Engineering Societies Building, but we believe that a large proportion of engineers are tiring of the craze for bigness, and are beginning to ask themselves whether discrimination, economy, and techno-scientific advance are not preferable to a world's record in membership and committees.

We would again remind those who may be interested that, if such a plan as we have outlined could be consummated, a large amount of intelligent and willing labor would be involved. Not only should each abstractor be in close touch with his specialty, he must be interested in it; he must see that all the available literature on the subject, and in the periodicals submitted to him, is represented in the index, so long as it is worth abstracting and so long as it deserves a wider audience. At present it happens often that an article is referred to or an abstract is made, whereas all subsequent criticism and discussion of the article remains unnoticed. In many cases the value of a contribution to technical literature lies almost entirely in the facts that are elicited during subsequent discussion. The abstractor must keep his eyes open for all references to the subject for which he is responsible. Abstracting is no mechanical operation; to be effective it must be performed conscientiously and with thoroughness. It should be realized also that the editorial columns of the technical journals often contain facts or comment that should be indexed or abstracted. We make mention of this because the majority of abstractors appear to think that such material, because it is unsigned, should be disregarded, whereas it is an integral part of the technical literature of the day. We have exceeded the space limit in drawing attention to a matter that should be viewed as one of vital import to the industry, but we have done so in the hope that our remarks will elicit the opinions of others, together with suggestions, from those who agree with our contentions, as to how the proposal can be put into more concrete shape.

Operations of the Engels Copper Mining Company—II

By Arthur B. Parsons

THE MILL. In a previous article the history of the Engels Copper Mining enterprise was reviewed briefly; the ore deposits in the two mines owned by the company were described; the methods of mining were discussed in some detail; and attention was drawn to sundry features of the mine equipment both underground and on the surface. The present article will deal with the concentration of the ore by froth-flotation in the mill at the Superior mine, one of the two neighboring mines owned by the company. This plant, at the time only partly completed, was first put into operation in February 1918. Additional equipment was installed during 1918 and 1919, and, in November of that year, when the old flotation plant at the upper mine was permanently shut-down and dismantled, the newer of two Minerals Separation machines, which had served there for two years, was moved to the Superior mill; here it supplemented the larger machine already in use. One 7 by 10-ft. tube-mill, one 8-ft. by 36-in. Hardinge mill, and two Dorr classifiers from the old mill also were moved to the new plant. Sundry minor alterations were made during 1920 to increase the capacity and improve the extraction. So far as crushing and grinding equipment is concerned the plant has a capacity of 1400 tons per day, but the flotation machines are inefficient when more than 1000 tons is being treated. Additional equipment will be necessary before the maximum tonnage can be concentrated economically. I shall describe only the new mill and the scheme of treatment in use at the present time.

COARSE CRUSHING. A small plant that merits brief attention is No. 6 Coarse-crushing plant, which derives its name from the fact that it is situated at the portal of No. 6 adit of the Engels mine. Electrically operated trains deliver the ore in mine-cars to an 800-ton flat-bottomed storage-bin above the crusher; the broken ore goes to a near-by bin at the loading terminal of the aerial tram that delivers Engels ore directly to the mill-bin. When the plant was originally designed, the ore was fed to the jaw-crusher by means of a wide horizontal belt-conveyor that ran lengthwise beneath the centre of the bin. This arrangement was unsuitable for the work, largely on account of the fact that the run-of-mine ore was coarse; chunks up to 200 and 300 lb. were common. The service was too severe for the belt and the labor required for operation was excessive. In re-building the plant, Robert A. Kinzie, who directs the operations of the company, replaced the conveyor and apron-feeders with a Meese & Gottfried pan-conveyor 36 in. wide and 52 ft. long from centre to centre of the head and tail pulleys. There are three openings at equal intervals along the length of the bin where ore can be withdrawn to feed the conveyor; the feed-hopper is mounted on a track in such a manner that it can be moved to any of the three, the

two not in operation being shut by horizontal steel gates. This permits the long narrow bin to be nearly emptied without shoveling, although ordinarily there is sufficient ore in the bin to make the moving of the feeder unnecessary. Another change was the housing of the motors in separate buildings. The crusher is 18 by 36 in., Blake type, manufactured by the Allis-Chalmers company. The bearings and the toggle-eccentric are water-cooled; the jaws are of manganese-steel. A 150-hp. Westinghouse induction motor supplies power for the crusher and the conveyor. A short inclined belt-conveyor carries the ore to the 450-ton bin at the tram-terminal. As it is now built this little plant crushes from 80 to 100 tons per hour with a maximum jaw-opening of 5 in.; the operation is smooth and economical. The ore from the Superior mine is hoisted in 5-ton skips that dump directly at the head of the mill into the 837-ton steel storage-bin, this being the same bin that receives the Engels ore as it is emptied from the buckets of the tram.

MILL-BUILDING. This is a frame structure; the sides are of 'rustic', painted light gray, and the roof is covered with asbestos roofing supplied by the Johns-Manville company. The timber and lumber were all cut in the vicinity of the mine by the company in its own saw-mill. The question naturally arises why structural steel and corrugated sheets were not used; the answer is that it was practically impossible to get steel at the time (1917-'18) when the plant was being built, whereas timber was available immediately. Moreover, time was an important factor; the completion of construction as soon as possible was desired on account of the high price of copper then obtainable. It will be observed from the accompanying illustration that the mill-site is unusually steep; there are more than a dozen benches with numerous concrete retaining-walls. Much of the underlying surface is solid rock; accordingly, massive concrete foundations are few. The ore-bins, one for coarse and four for fine ore, are of steel plate, 30 ft. high and 24.6 in. diameter with an available capacity of approximately 700 tons each. The plant was designed by Bradley, Bruff & Labarthe, and that firm supervised the erection.

A feature that may, I think, be called unique is the building of the entire plant so high up the hill that the concentrate must be lowered 100 ft. vertically from the filter-floor to the railroad. The illustration shows the housing of a steeply inclined conveyor below the main portion of the mill-structure. This is so steep that the comparatively dry concentrate rolls down the belt, thereby requiring constant attention and increasing the cost of handling. It is apparent too that there must be great waste in time and power in carrying supplies up the hill, and in the time of employees going to and from the warehouses and shops that are situated below.

The reason assigned for selecting the site is that it made possible a gravity flow of tailing to the impounding dam, a mile down the canyon. The laws of California make it obligatory to clarify the waste-water before it is returned to the stream and for this purpose a settling-plant consisting of a series of classifiers and an 80-ft. Dorr thickening-tank was built above the dam. The desire to have the tailing flow by gravity to this tank determined the choice of the site. It seems probable that the cost of pumping the tailing a short distance would be more than offset by the other apparent savings. W. R. Lindsay, the superintendent, does not agree with this view; and it must be admitted that the calculation of the net financial loss arising from lost time is hard to measure. Workmen need rest occasionally, and it may be that the time consumed in waiting for the tram, and in riding on it, supplies this need. The two tram-cars that serve the mill are operated by electric hoists on tracks that can be seen on either side of the plant.

CRUSHING. The equipment for crushing consists of one No. 8 Traylor gyratory, two No. 5 McCully gyratories, and one set of Superior rolls, 54 by 24 in. These are arranged at the present time as indicated in the accompanying flow-sheet. The trommel makes three products of the following sizes: (a) through 1-in. round holes, (b) through 2-in. holes, and (c) oversize. The oversize goes to the rolls for re-grinding; the 2-in. and 1-in. products are divided between the storage-bins for the Marey and Hardinge mills.

A second trommel is being added; when it is complete both will be equipped with 1-in. screens exclusively, and the rolls and trommels will be arranged in closed circuit; the rolls will be operated with a choke-feed, thereby increasing their capacity. The change in feed will likewise be beneficial from the standpoint of efficient grinding because of the less ratio of diminution required of the ball-mills.

A few notes on the crushing equipment may be of interest. Ore from the 'coarse' bin is fed by means of a 30-in. Meese & Gottfried pan-conveyor operating in a tunnel through the foundation of the tank. Like the conveyor beneath the bin at No. 6 crushing plant, it gives excellent satisfaction. The Traylor crusher, breaking the ore to pass through a 3-in. slot, has given good service, but the No. 5 McCully gyratories do not appear to be rugged enough for the work expected of them; trouble has been experienced with the cracking of both the upper and lower halves of the shell. It must be admitted that the ore is unusually hard and tough, especially that coming from the Superior mine, but it is hard to believe that the ore itself accounts for the repeated breakage. At present there is no means for removing 'tramp' iron except that the operator picks out pieces by hand when he happens to see them. Although I am assured that the cracking has not always been caused by stray chunks of metal, it is significant that plans are already made to provide a magnet to assure the removal of hammer-heads, drill-bits, and such scrap, which are always found in ore, and some of which are almost certain to escape the atten-

tion of the crusher-man, whose duties take him away from the crusher at times. The relative position of the crushers and bins and the arrangement of chutes, set in concrete, is peculiar and has delayed the installation of a magnetic device. Concaves and heads for the gyratory crushers are made of manganese-steel.

The roll-shells are likewise of manganese-steel. An unusual feature is the sectional construction. There are nine arc-like segments each independently attached to the roll by means of a curved bevelled 'mortice' with a filling of zinc. These shells have proved entirely satisfactory from an operating standpoint in spite of some apprehension at the outset that a single segment might become loose and wreck the entire machine. They are expensive, of course; a complete set at war-time prices for steel cost \$3000. The cost per ton of ore crushed will not be known until the first set is worn out, but, judging from the tonnage that has passed through the rolls already, the net cost will be comparable with shells of cheaper material, particularly in view of the present lessened comparative cost of manganese-steel.

The rolls were run formerly at 110 r.p.m.; by reducing the speed to 54 r.p.m. the consumption of power was diminished by 40% and the capacity was increased. The crushed ore goes to the appropriate steel-tank storage-bin as indicated in the flow-sheet. It will be observed that the crushing part of the plant is a distinct unit; either the crushing department or the grinding-flotation department can be run independently of the remainder of the mill. This arrangement has obvious advantages, especially as the storage capacity of the four bins is equivalent to several days run, thereby affording desirable elasticity in operations.

GRINDING. The ore from two of the bins is fed to the mills by means of 18-in. pan-conveyors and from the other two by means of 30-in. belt-conveyors; the latter do the work just as well and are preferable because of cheaper maintenance. This emphasizes clearly the need for selecting the equipment that is most suitable for the particular service. Mention has been made of the fact that the run-of-mine product could not be efficiently moved by means of a rubber belt; on the other hand, the crushed ore is handled most economically on a belt.

The Marey mill (No. 86) and each of the three 8-ft. by 36-in. Hardinge mills is followed, in a separate unit, by either a 6 by 12-ft. or a 7 by 10-ft. tube-mill or a Hardinge mill used as a re-grinder; for convenience, each of the eight mills is arranged so that it may be run in closed circuit with a 6 by 21-ft. Dorr classifier. Usually, however, the coarse product from the primary classifiers forms the feed for the re-grinders. The detailed arrangement may be seen on the flow-sheet. One of the classifiers is a type C machine; the others are type D. The experience here has been that the heavier machine, type D, is far more satisfactory. One reason for this is the fact that the machines have been speeded up to 23 strokes per minute, as compared with a normal of 18 to 20, with the purpose in view of causing sufficient agitation to maintain an overflow in which 10%, by dry weight, of the

TRAYLOR GYRATORY CRUSHER

SILENT-CHAIN DRIVE FOR BALL-MILL

solid material is coarser than 100 mesh. The desirability of this will be mentioned in the discussion of flotation. The Marcy mill is equipped with manganese-steel liners and chrome-steel screens, and is fed with 5-in. chrome-steel balls.

The Hardinge mills are provided with chilled-steel

liners and chrome-steel wedge-bars. It has been found, however, that soft spots in the chilled steel wear rapidly to the shell of the mill, thereby necessitating replacement when as much as 60% of the entire liner remains. Economy of material and of time in repair-work will be effected by substituting chrome-steel liners. This is now being done as current replacements become necessary. The re-grinding mills are fed with 2-in. Duroloid balls furnished by the Los Angeles Foundry Co. They have been found by competitive tests to be the most economical ball available.

All the mills are driven by individual motors; the Marcy and tube-mill motors are direct-connected to the pinion-shafts, whereas the Hardinge pinion-shafts are connected to 150-hp. motors by short-chain drives. Two of these are of Link-Belt manufacture and the third is a Morse silent-chain drive. All of the chains run in No. 3 Keystone grease and are thoroughly protected from dust and dirt by metal housings. The Marcy-mill pinion was manufactured by the Fawcett Machine Co.; those on the tube-mills are of the Falk type. The wear on the pinions was materially lessened by using Gearshield, made by the Ironsides Manufacturing Co. Some pinions formerly lasted only three months; similar pinions running in Gearshield are still in service after a year of operation.

Mr. Lindsay and W. I. Nelson, general foreman of the mill, are obtaining data for publication from a complete series of tests to determine the efficiency of the various grinders and re-grinders. From these I have taken the following figures, the particular tests recorded having been made with the Marcy mill followed by tube-mills. When handling 2-in. feed one 6 by 12-ft. tube-mill was sufficient, whereas with 1-in. feed, two tube-mills were required to grind the oversize from the Marcy.

Size of feed	Finished product, tons	Power input, kw	Power input, kw hr.	Kw-hr. per ton ground
2-in. ring	443.97	281	6744	15.1
1-in. ring	860.10	387	9288	10.7

These figures reveal two interesting facts: the decided

FLOW-SHEET OF THE NEW MILL

decrease in the gross power consumption per ton of ore crushed; and the increased capacity obtained from the ball-mill—both being accomplished when finer crushing has been effected in the rolls. Three mills are required instead of two but the increased capacity of the three-machine unit is far out of proportion to the additional cost of balls and liners, and the labor for repairs and operating attendance, that the third mill entails. In order to study intelligently the merits of finer crushing in the rolls it will be necessary to analyze all the elements of cost in both roll-crushing and subsequent grinding. If a new plant were to be erected the factor of capital expenditure would have to be considered but in this instance Messrs. Lindsay and Nelson will confine their investigation to the actual operation and maintenance of the present equipment. The results should be interesting as well as valuable.

The following figures cover the operations of the year 1920, for all the mills:

Material	Total weight used, lb.	Consumption per ton of ore milled, lb.
Balls, 5-in.	380,452	1.588
Balls, 2-in.	219,578	0.917
Liners	126,610	0.528

FLOTATION. The overflow from the eight Dorr classifiers is automatically sampled as it passes to a 20 by 10-ft. tank, provided with Dorr thickener rakes, in the flotation department. This tank serves as a collector and is called a 'surge' tank for the reason that it absorbs surges in the flow of pulp to the flotation machines; in other words, it provides a feed for the machines that is uniform, both in quantity and in dilution. Freedom from sudden fluctuation is recognized as essential to good concentration by flotation and this scheme for obtaining it has proved highly effectual. Besides the overflow from the classifiers, tailings from the cleaner-cells and accumulated pulp from a clarifier enter the surge-tank; there is no overflow, but the level of the pulp is maintained at a point 15 or 20 in. below the top by the withdrawal of the flotation feed through the central discharge at the bottom of the tank. A six-inch centrifugal pump lifts the pulp more rapidly than is required for the flotation machines, the excess joining the feed to the surge-tank. Additional agitation and mixing are thereby obtained.

Sodium hydroxide was used formerly as a flotation reagent; it had the effect of stiffening the froth and improved the extraction somewhat, but coincidentally there was some diminution in the grade of the concentrate. It was found to be more profitable to discontinue the using of the hydroxide. The method of introducing oil is peculiar; three mixtures are prepared using the following ingredients.

- A. Diesel oil, 24
- B. fuel-oil from the Standard Oil Co.
- B. No. 14 crude pine-oil high in turpentine.
- C. No. 7 fuel-oil, standard grade.
- D. Kerosene oil.

The mixtures are:

	No. 1	No. 2	No. 3
	%	%	%
A	85	40
B	15	15	35
C	75	..	25
D	10

The former practice was to use a standard mixture of B, C, and D. However, it was found that variations in the character of the ore were sufficient to require changes in the constituent proportions, if the best results were to be obtained; the various mixing formulas were accordingly developed. According to Mr. Nelson, the froth that formed when using a mixture of C and B was tough, and the grade of the resultant concentrate was low. Diesel oil (A) in combination with pine-oil (B) produced a clean froth or concentrate, but if the proportion of oil in the pulp fell below the ideal amount the froth could not carry the sulphides and a high tailing resulted. On the other hand, an excess of oil could be used without making a noticeable difference in the condition of the froth, thereby causing a needless use of oil. For these reasons the fuel-oil (C) is added to the mixtures, which are so devised that a wide range in the proportions of A, B, and C oils may be obtained by adding different amounts of No. 2 and No. 3 mixtures.

No. 1 is added at the head of the Marey mill; No. 2 and No. 3 at the tube-mills, or, if necessary, in the first compartment of the flotation machine. Control of the oil-feed is centralized at one point near the machines so that the operator is able to make adjustments easily and quickly. It is desirable to add as much as possible of the amount required before the Minerals Separation machines are reached, for the reason that raw oil kills the froth. However, an excess of oil is to be avoided, and accordingly the practice is to keep safely on the 'low' side in the mills and to make up any deficiency by adding some of the mixture, richest in frothing-oil, in the cells. This scheme of proportioning and adding the oils is unusually complicated, but the good results seem to answer any criticism.

During the month of March 1921 the amounts of the various oils used were as follows:

	Amount used per ton of ore milled, %	Proportion of total, %
A	0.5945	51.91
B	0.2895	25.28
C	0.2443	21.33
D	0.0170	1.48

The M. S. equipment consists of one new 12-compartment, 24-in. type A-2 machine, and one 12-compartment 18-in. type G machine salvaged from the old mill. They have been modified slightly by providing adjustable redwood gates to regulate the flow between compartments, together with a curved baffle, beneath the opening from the mixing into the frothing-chamber, which deflects the pulp upward and lessens the tendency of particles to go from cell to cell without getting into the zone of frothing.

The two Minerals Separation machines operate in parallel, each making a finished concentrate, and three additional products that are re-treated in Callow cells. These cells have been altered by placing a false bottom above the former bottom to reduce the slope; the fall now is 25 in. in 8 ft., as compared with 36 in. Formerly the blower tended to overheat. One cell was remodeled without any ill effect on the results, and accordingly the others were re-built in the same way. Air is introduced

through eight canvas-covered cast-iron pans each 12 by 24 in., provided with individual air-pipes entering the pans from the bottom.

Numerous changes have been made in the flow-sheet for this part of the mill and still others are planned. However, the flow illustrated herewith has given consistently good results.

It will be noted that the final tailing comes from only two cells; likewise that only two cells make a finished concentrate. The others serve as roughers to make intermediate products for return to the surge-tank or for further treatment in other cells. The question may be asked why the final cleaning of the tailing is done in only two Callow cells when a number of others are idle. As a matter of fact, when a decreased tonnage is being crushed, one of these two cells is cut out and the entire flow diverted to a single cell. This procedure is based on the theory, doubtless sound, that unless the quantity of oil and of floatable mineral in a cell exceeds a fixed amount, the froth formed will not be sufficiently enduring to overflow the cell. No oil whatever is introduced beyond the point where the pulp enters the M. S. machines.

Krogh centrifugal sand-pumps are used exclusively for returning pulp. The lining and impellers are made of special white iron. In order to minimize variety in sizes of repair-parts, pipe, and fittings, three-inch pumps are used throughout, with the exception of two 6-in. pumps for transferring pulp from the surge-tank to the flotation machines. A measure for efficient operation is the providing of duplicate pumps so that no delay need result from the temporary shutting-down of one pump for repairs. Another item of standard equipment is the Merco-Nordstrom plug-valve; it costs less than a gate- or globe-valve, is fool-proof, lasts longer, and is free from the two great defects of the ordinary cock, namely, liability to leak and to stick so that it cannot be turned. So well liked are the Merco plug-valves that they are being introduced also in the mine.

FILTRATION OF CONCENTRATE. The concentrates from the two M. S. machines and from the Callow finishers combine in a single launder, and, after being sampled, flow to a collecting and dewatering tank, 16 by 16 ft., provided with Dorr rakes. The overflow from this tank goes to a second tank similar to the first except that it has no rakes; periodically the settled sludge from the second tank is pumped back to the surge-tank while the overflow passes through a square settler and to waste. The overflow from the Dorr tank is not clear; as a matter of fact, it is essential that it be not clear, for the reason that the concentrate contains an undesirable proportion of 'colloidal' material, mostly silica, which seriously interferes with efficient filtration, but which will overflow from the Dorr tank if it is given the opportunity. Some of the colloidal silica settles in the second tank and is pumped back, but it does no harm.

One 12 by 8-ft. Oliver filter dewateres the concentrate produced at present without difficulty, but an 8 by 6-ft.

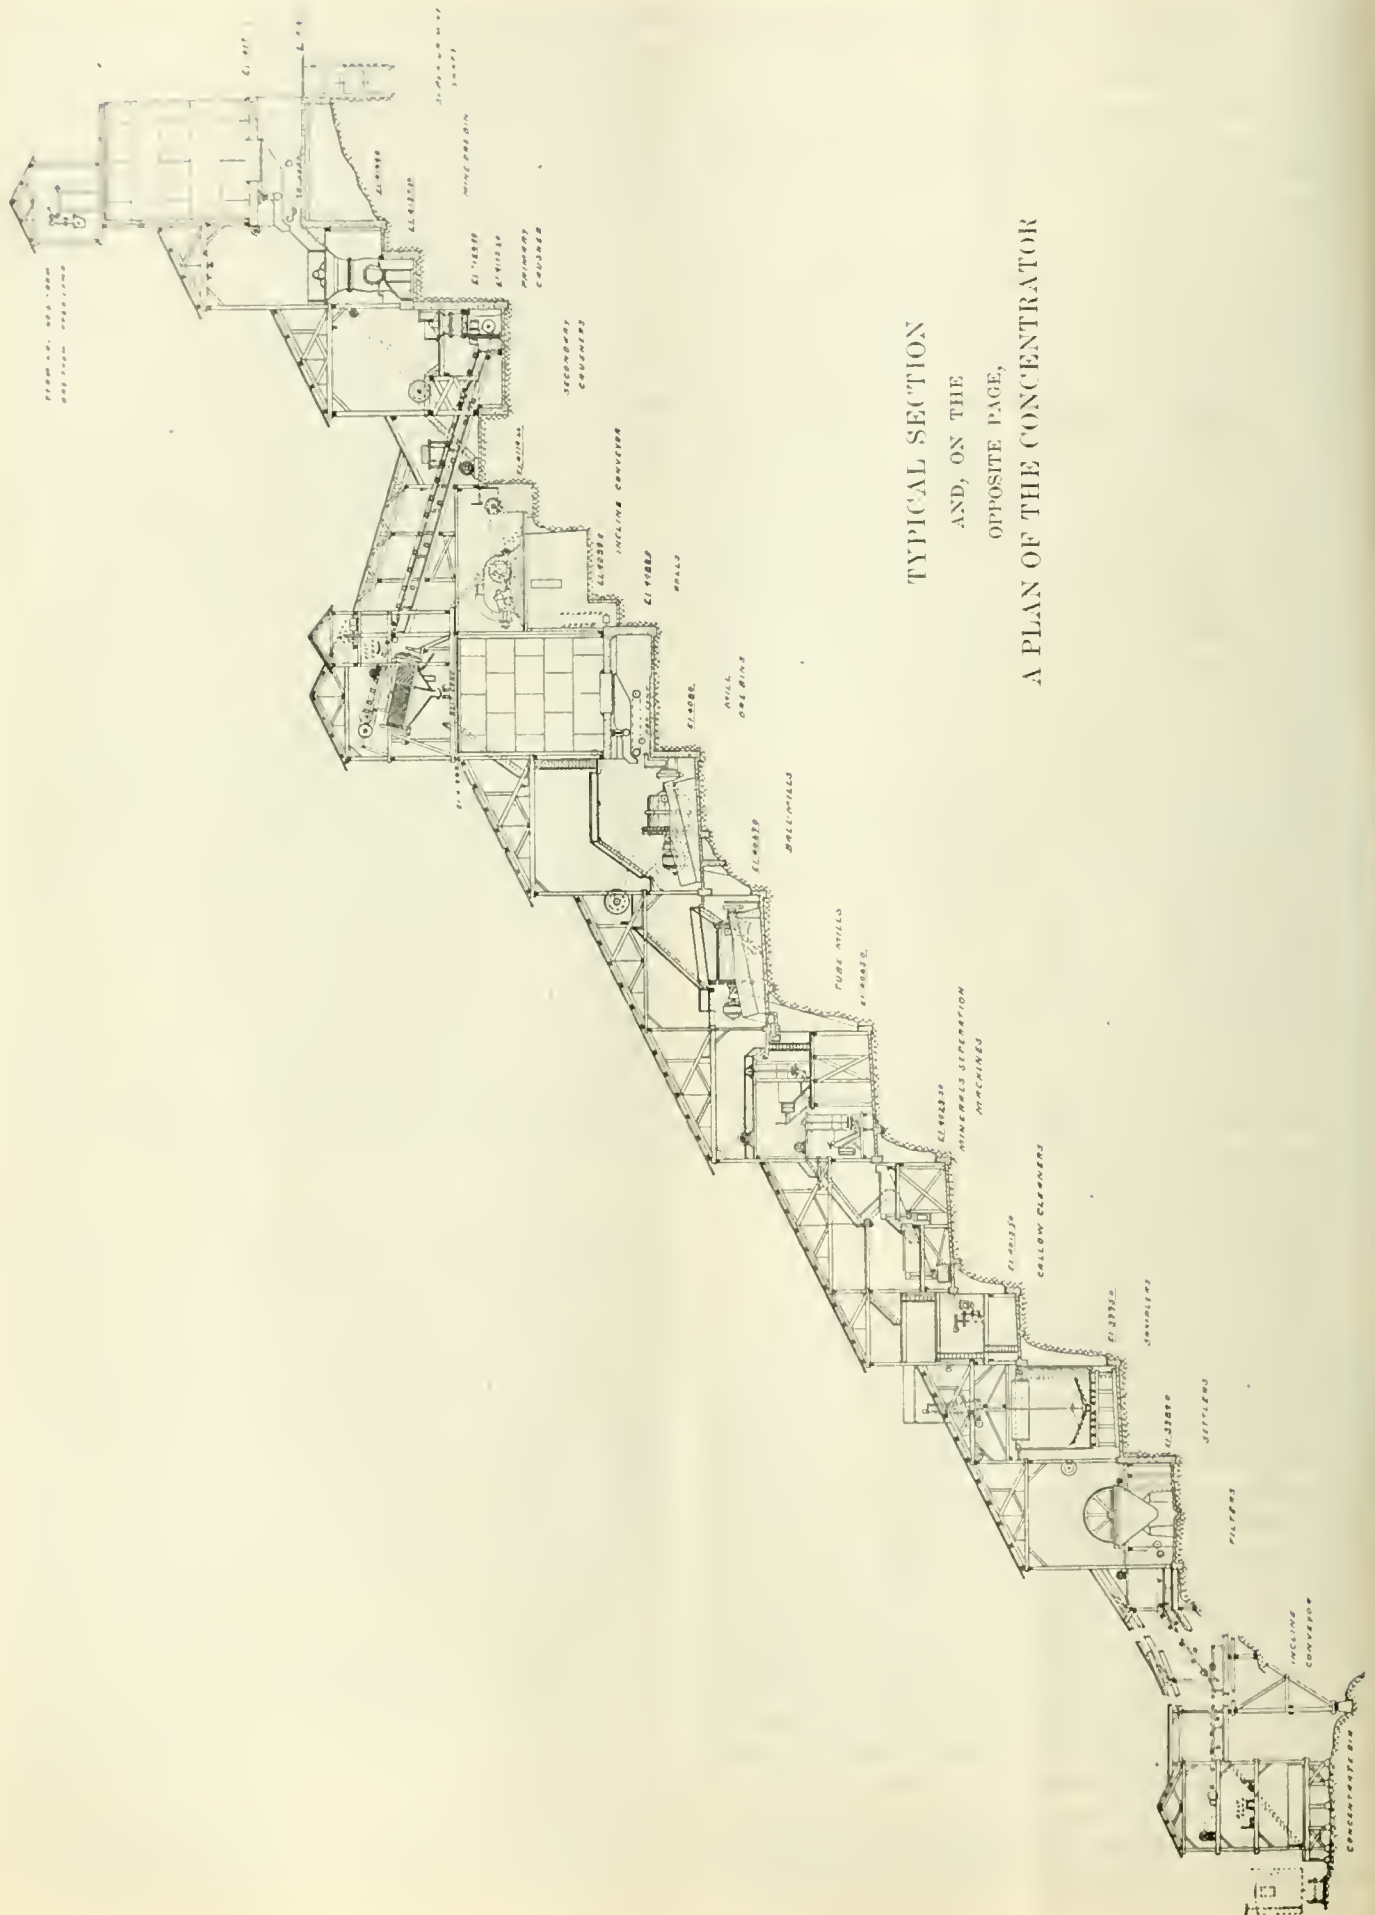

Oliver is to be installed to provide increased capacity, and likewise to serve in emergency.

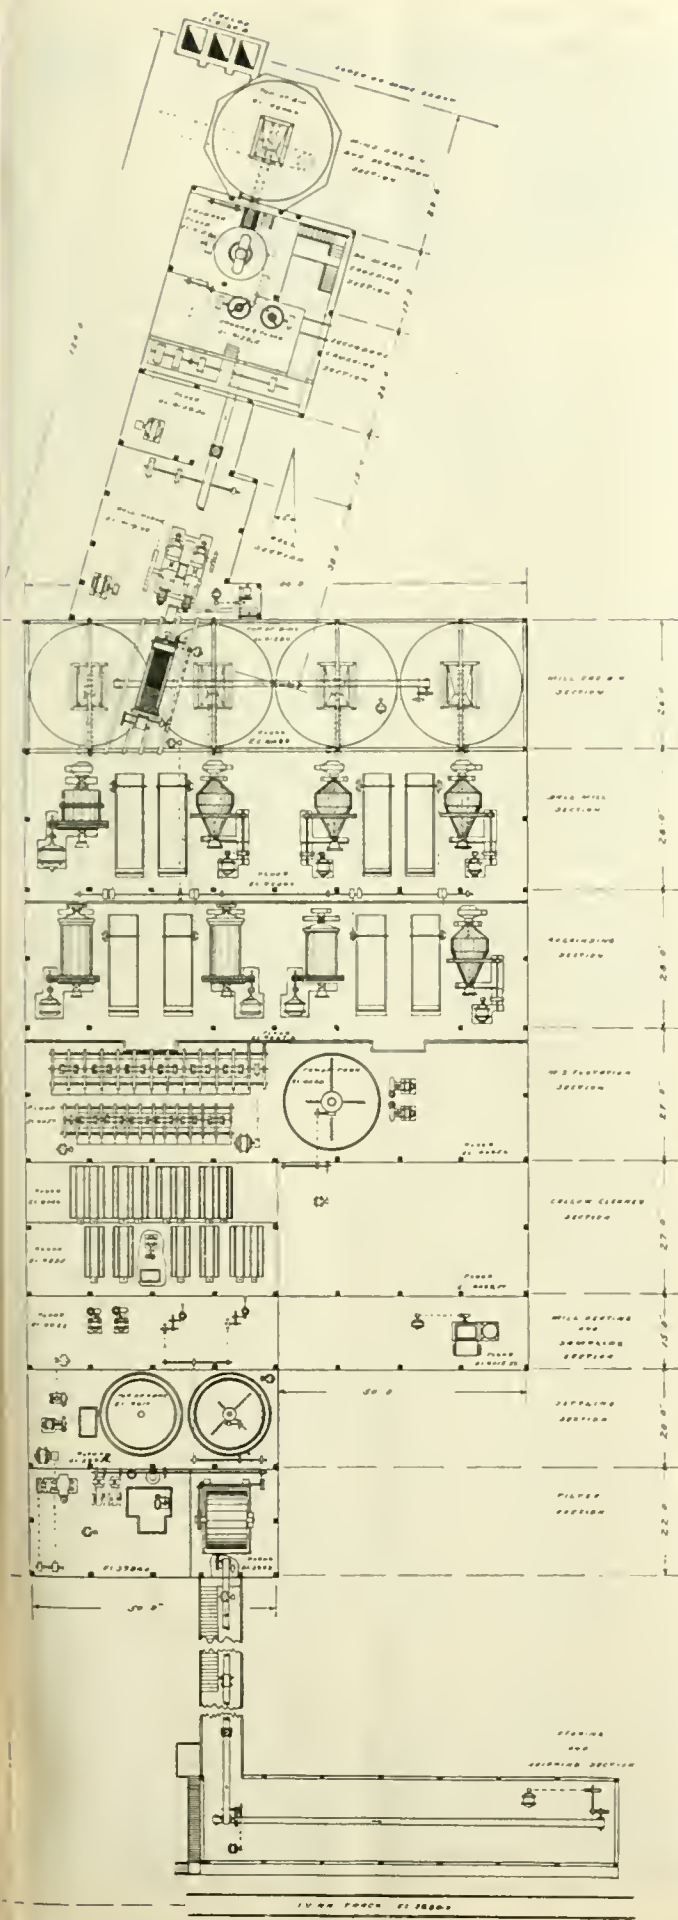

Colloidal slime clogs the fabric of the filter cover and tends to make an impervious cake; the result is a thin and wet cake, or, in other words, low capacity and high moisture. This is avoided (1) by removing as much of the colloidal matter as possible by keeping the contents of the thickener slightly agitated and (2) by maintaining a flotation feed in which the plus 100-mesh material forms approximately 10% of the total. In addition, the pulp withdrawn from the thickener is kept thick, the ratio of solid to water being not less than 1:1. The result is a cake varying in thickness from $\frac{3}{4}$ to $1\frac{1}{4}$ in. and in moisture content from 10 to 15%. A No. 12 M. S. canvas cover supplied by the Oliver company has an average life of five months of effective filtering. It has been found desirable to heat the pulp in the filter with steam in order to keep open the pores of the cloth.

There is no question but that finer grinding would result in a higher extraction in the flotation department, but here an economic balance must be struck. There is no profit in recovering a few additional ounces of copper, per ton of ore, if the added cost of grinding and filtering, and freight on extra moisture, will more than equal the revenue from the copper saved. The final test of good metallurgy is financial gain—not low tailing nor even high-grade concentrate. It is the task of the wise metallurgist to determine the method of concentration that will net the greatest profit. The operation of the Engels mill is a good illustration of the correct recognition of the wisdom of such a policy.

Miscellaneous equipment in the flotation department includes: duplicate vacuum pumps, 14 by 8 in., manufactured by the Doak Gas Engine Co.; a No. 8 Sturtevant blower for the Callow cells; and a Sturtevant fan used in conjunction with a steam-heating system for the mill.

Concentrate from the filter falls through a steep chute onto a 12-in. belt-conveyor that carries it down a 34° incline into the storage-bin adjacent to the railroad sidetrack. It is this conveyor that was mentioned earlier in the article as requiring constant attention because of the tendency of the partly-dried concentrate to roll off the sides of the belt. Mr. Kinzie recently has designed an arrangement in which a belt-conveyor, operating at a practicable inclination, will be combined with a vertical chute to transfer the concentrate. If the plant were to be re-designed the filtering department would doubtless be at the bottom of the hill beside the railroad track. The filter-floor would be at such an elevation as to provide conveniently for the delivery of the concentrate by gravity either to storage-bins or directly to the cars. The concentrate, as a pulp, would flow to the filter-plant through pipes or launders and the clear filtrate would be pumped back, or not, as desired. Obviously, this scheme depends upon the assumption that the mill-structure proper would be placed in its present position far above the grade of the railroad instead of near the bottom of the slope.

From the present storage-bin, box-cars are loaded with concentrate by wheel-barrow for shipment over the Indian Valley and Western Pacific railroads to the Garfield smelter in Utah.

The disposal of the tailing is complicated by the law prohibiting the contamination of streams with muddy water. Accordingly, a dewatering plant has been constructed above the concrete tailing-dam. The stream from the main flume flows into the first of three Esperanza classifiers arranged in series; these remove a large proportion of the sand, leaving the thin slime to flow into a 16 by 80-ft. tank equipped with Dorr thickener rakes. Lime emulsion is added to assist settling, the proportion during 1920 averaging 1.76 lb. of dry lime per ton of ore milled. The present storage-area is not adequate and it is difficult and expensive to maintain a clear overflow from the ponds to the creek; moreover this will be aggravated when the anticipated increase in tonnage treated is realized. The work of building new settling-ponds in the Stark ranch, owned by the company, is progressing; when this is concluded a material reduction will be effected in the cost of dewatering, which during 1920 amounted to \$0.1699 per ton of ore milled.

The metallurgical results are determined accurately. To ascertain the tonnage, two Merriek weightometers are provided: the first records the weight of the ore carried by the belt-conveyor between the No. 5 crushers and the rolls; the second weighs the concentrate but serves only as a check, for the extraction made at the mill is calculated from the actual weight determined at the smelter and from the assays on which settlement is made. Particular care is taken with the moisture sample of the mill-heading.

Pulp samples are taken automatically at three points by intercepting the flow in (1) the main launder leading to the surge-tank; (2) the concentrate launder leading to the filter feed-tank; and (3) the tailing flume. The automatic sampling devices are of the swinging type, carefully designed to obtain a fair sample. They are actuated through reducing-gears by the mill-machinery, but are constructed in such a manner that, when released, the 'cutter' will complete its swing even though the power may 'go-off' and shut-down the plant. Many samplers of this type have the fault of coming to rest near the centre of their swing, thereby catching the drainings from the launder until power is restored. The accuracy of the weightometers is verified by actual weighing at intervals of several weeks, when they are re-calibrated if necessary; the machine weighing the heading gives consistent results and is particularly reliable.

The following data summarize the mill results for 1920:

Ore milled, tons	239,012
Average heading assay, copper, %	2.21
Average tailing assay, copper, %	0.4514
Concentrate produced, lb.	28,799,796
Average concentrate assay, copper, %	29.76
Copper in concentrate, lb.	8,571,571
Silver in concentrate, oz.	119,165.42
Gold in concentrate, oz.	1,217,872
Actual extraction, %	80.93

The itemized cost per ton during 1920 is shown in the following table:

Account	Operation	Repairs	Total
Crushing	0.0467	0.0489	0.0956
Classifying	0.0023	0.0042	0.0065
Rolling	0.0001	0.0058	0.0059
Grinding	0.1021	0.0850	0.2477
Re-grinding	0.0882	0.0214	0.1096
Conveying	0.0092	0.0070	0.0163
Pumping	0.0014	0.0153	0.0197
Concentrating	0.0923	0.0132	0.1055
Filtering	0.0262	0.0104	0.0366
Dewatering	0.0714	0.0985	0.1699
Power	0.2909	0.2909
Assaying	0.0086	0.0086
General	0.0146	0.0146
Heating and lighting	0.0816	0.0816
Boarding-house loss	0.0317	0.0317
Total	0.9303	0.3103	1.2407

POWER. Aside from that supplied by a 350-kw. hydro-electric generating unit, power is purchased from the Great Western Power Co. The first transmission line, completed in 1915, was 45 miles long, connecting with the Butt Creek power-house; the construction was partly financed by the Engels company. When the erection of the new mill was definitely decided upon, arrangements were made with the Power company to construct a second line from the Las Plumas plant. Current is transmitted 57 miles at 44,000 volts to the Veramont sub-station; thence 10 miles to the mine at 22,000 volts. The transmission lines pass through timbered country for the most part and the service until recently was not efficient; the supply of current was interrupted frequently. Moreover, the rates in the existing contract were not favorable to the mining company. During 1920 Mr. Paxton devoted a great deal of time to litigation, hearings before the Railroad Commission, which determines rates for all public utilities in California, and negotiations with the power company; the outcome was a compromise agreement dated December 9, 1920. By the terms of this agreement the Great Western company undertook to spend \$5000 on improvements to the Las Plumas line; pending lawsuits for damage suffered by the Engels company were dropped; and a new five-year rate-contract was signed. Since January the service has been improved and the average cost per kilowatt-hour has been reduced from 1.6 cents to approximately 1.0 cent, thereby effecting an estimated annual saving of about \$50,000.

INDUSTRIAL RELATIONS. The company owns the land on which the mine settlements are situated and enjoys the advantage of entire control over its employees; the policy is to make conditions as satisfactory as possible. Running water and electric lights are provided in 120 cottages reserved for the use of married men and their families. These cottages have from 3 to 5 rooms and make first-rate homes. Eight dormitories have been built for men without families. The newest one is a two-story building designed to accommodate 66 men, two in each room. Steam-heat and electric lights are provided, and the beds have comfortable springs and mattresses with blankets, sheets, and pillow-cases, supplied by the company. The atmosphere is very different from that of the bunk-house that was so common in our Western mining districts a few years ago.

At the company boarding-houses clean wholesome food is served in attractive dining-rooms. Mining companies, with few exceptions, have always served good food, and this tendency has become more marked during recent years. It is the boast of about one manager in every three that he feeds his men better than any other mine in the particular State in which he happens to be; accordingly, comparisons are not particularly convincing to those familiar with the subject. However, during 1920 the average cost to the Engels company of operating the boarding-houses, exclusive of dormitory expense, was \$1.55 per man per day, which ought to support my statement, based on personal observation, that an exceptionally good table is set. The employees are charged only \$1 per day for board and lodging, the deficit that accrues being made up by the company, being charged directly to operation.

A commodious recreation hall, completed in 1918, is equipped as a reading-room, card-room, and billiard-hall; dances and motion-picture shows are held here one or two evenings each week. Employees purchase merchandise in the company's general store at prices based on the invoice cost plus the actual expense of conducting the business. Englemine also boasts a good school-house.

Prior to 1920 the turnover of labor at the mine was extremely high in spite of the endeavor on the part of the company officials to provide comfort and recreation for the employees. The completion of the new dormitory during that year assisted in simplifying the labor problem, but the influence of a surplus of job-seekers throughout the country should be recognized as an important factor. At the present time a stable, efficient, and apparently well-satisfied force of about 400 employees operates the mine and mill. The various foremen seem to co-operate to excellent advantage under the leadership of Mr. Lindsay.

It may be of interest to mention the men who are officially identified with the affairs of the company, in addition to Mr. Kinzie and Mr. Paxton. Henry Engels is president, F. Klamp is vice-president, Mr. Paxton is treasurer as well as manager, and L. A. Bell is secretary. The Board of Directors comprises, besides the president, vice-president, and treasurer, the following: J. F. Humburg, I. J. Truman, Jr., Richard Spreekels, O. G. Traphagen, Geo. T. Cameron, and C. Hedemann.

In conclusion, I may say that within the last month work actually has been started at the upper mine on the driving of an adit at an elevation of 690 ft. below No. 6 level to serve as a new main haulage-way. The portal of the new adit is near the site of the old smelter. The tentative plan is to continue the mine-tracks to the storage-bin at the mill, thereby delivering the ore without transfer directly from the stope-chutes to the mill-bin. This will ultimately do away with the coarse-crushing plant at No. 6 and the aerial tram, with consequent economy. The orebodies being developed on the 7th level, 200 ft. vertically below the 6th, are fully satisfying expectations based on diamond-drilling, and the outlook for the future success of the enterprise is excellent.

DISCUSSION

Revision of the Mining Law

The Editor:

Sir—The text of the proposed bill to revise, amend, and codify the laws of the United States relating to the location of mining claims on the public domain, and for other purposes, as published in your issue of June 18, should be discussed for the purpose of revealing its effects, if any, upon our mining industry, in case it becomes a law.

Apparently, the text does not show any material changes in the existing mining law except the added clause that provides for the acquisition of large areas of the public domain for the purpose of storing mill-tailing and other like material; and the repealing of the so-called Apex Law with its extra-lateral features, which has always been an eyesore to the mine operator and a boon to the prospector and miner, who take the initiative in the development of mining districts.

During the last score or more of years, there has been acquired a more thorough knowledge of the genesis of ore deposits, their mode of occurrence, and their relation to geologic structure. Possessing this knowledge in connection with our prospecting and mining experience, we should readily distinguish mineralized land from non-mineralized, and the local spots within the former that are likely to prove of commercial importance; and, ordinarily, we would be able to predict the probable future of our mining industry. But here comes a proposed revision of the laws under which our mining industry has flourished, and still flourishes. This proposed revision seems to be perfect in theory, but useless in fact. It embodies the bending of the natural laws to conform to human laws; the existing laws involve the twisting of the human laws to accord with the natural laws.

Before discussing the merits of the proposed law, or its objectionable features, it would be well to ascertain how much of the surface of the earth would be applicable when its provisions become effective; or, to be more explicit, to find out how much there is of the unappropriated public domain that shows on the surface such geologic features as indicate a probable commercial ore deposit below.

This point needs to be emphasized. Then, broadly speaking in reference to the mining industry of the Western States, it is safe to assume that the area of land in the public domain that would be appropriated under the provisions of the proposed bill is negligible as compared with the area of land that has been appropriated under existing or previous mining laws of the United States.

The truth or falsity of this assumption may be shown by the apprehension of the facts pertaining thereto. This may be done (1) by obtaining from the General Land Office an official map showing the extent and situation of the several parts of the public domain, and the extent of the different areas therein designated as mineral land; (2) by obtaining, from the Surveyor General or the Surveyors General of the several Western States, maps showing the relative position and boundaries of all patented mining claims in each mining district within his jurisdiction; and securing a report on the same, made by competent mining engineers; (3) by obtaining, through the U. S. Geological Survey or other reliable source, a map of each mining district, showing the boundaries and relative position of every unpatented mining claim located therein; (4) and, then, segregating the mineralized lands of the public domain into two divisions; the first, to include the unpatented mining claims; and, the second, the unappropriated residue. Then let the Geological Survey or a corps of practical mining engineers report the real and prospective value of the former, and determine how much of the latter, if any, is worthy of a location notice.

The ascertained result of such a wide investigation would remove all doubt and misapprehension as to the truth of the above proposition. This conclusion is supported by actual observations and cumulative investigations; from which we may infer (1) that the primary cause for the general disappearance of the prospector from his chosen field is that the whole of the Cordilleran region from Canada to Mexico has been so thoroughly searched by prospectors, miners, and others, for ore deposits that the possibility of discovering other ore deposits is so remote that a great majority of the prospectors are following other vocations for a livelihood; (2) that the land appropriated under the provisions of existing or previous mining laws contains nearly all of the mineral wealth, and our mining activities hereafter will be practically confined to the operation and the development of existing mines and mining claims.

From the day that the proposed revision becomes a law, as it would not affect existing mining claims as to their extra-lateral rights, it is evident from the above that the present mining laws as interpreted by the courts will continue to dominate the development of our mineral resources; and that the revised law would practically be useless in fact and somewhat crippled in theory.

There is a strong probability that all 'porphyry coppers' have made necessary provisions for the impounding of their tailings, and, the statement "that all the 'porphyry coppers' have been discovered" is well-nigh a

certainty; these, taken together, show that there is little need for large areas of land for the storage of tailings and other residues. But, should it ever be necessary to have large areas of land for storage purposes, an adequate and conveniently situated site, with absolute title, could be secured from individual land-owners with less trouble and expense than it could be appropriated under Section 13 of the proposed revision bill.

In every mining district of any importance there are generally one or more producing mines and several promising prospects or mining claims extending in various directions and clustered around these producers. After this proposed bill becomes a law, many mining claims are likely to be abandoned, to be subsequently re-located under the provisions of the revised law. In some cases, this may require four locations to cover the area of one abandoned claim, in order to have the claims conform to the sub-divisions of the Public Land Survey. In the course of time, most of the mining districts would contain several of these re-located or hybridized mining claims. These hybrids would be scattered throughout the district, and, in general, surrounded by claims located under the existing law. Thus, in every established mining district of importance, we would have two conflicting laws under which to operate and develop our mines and prospects. This shows the impracticability of the proposed revision bill.

J. R. JOHNSON.

Silver City, New Mexico, July 15.

Efficiency of Labor

The Editor:

Sir—Referring you to that most interesting article by Mr. H. Foster Bain, entitled 'Training for Foreign Exploration', which appeared in a recent issue of your paper, there is one passage that seems to require some explanation. He states:

"One must not conclude that raising wages cheapens production. It only does so when increased efficiency results from the added desire on the part of the men to hold their jobs or when it enables a particular employer to attract better men from others. Generally added efficiency in labor is purchased at an increased cost per unit, just as the added speed of a fast steamer calls for more coal per mile than when driving at a slower rate."

It is true that raising wages does not cheapen production. We have certainly found that, in the past five or six years of constantly increasing wages, the cost of production has also increased, not in proportion to the wage increase but in a greater ratio. This has been largely due to the decrease in the efficiency of labor. Hence, it is generally true that when wage-rates are increased labor efficiency decreases, especially on the straight wage system of employment.

On the other hand, I cannot understand Mr. Bain's point of view in that added efficiency means an increased cost per unit. Labor efficiency may be increased in various ways, by better working and living conditions, improved mining methods, and by certain bonus or contract

systems of employment. All of these mean an increase in the total cost of operation, but the unit cost of production is certainly decreased. I do not believe that the comparison of the efficiency of labor with the speed of a steamer was quite properly made. Greater speed may require more coal, but that is about all the additional expense that would be required, and the total cost per mile of operating would probably be decreased.

Just so with a mine. If 500 men produce 1000 tons per day and if by one or all of the means above mentioned the labor efficiency could be so increased that 1500 tons would be the daily output, it is quite obvious that the cost per ton would be decreased.

JOS. A. NORDEN.

Bingham, Utah, July 15.

'Pyrites' and 'Pyrite'

The Editor:

Sir—Referring to your editorial on page 46, of the 'Mining and Scientific Press' of July 9, relative to 'pyrites' and 'pyrite', permit me to suggest that your reduction of the clause to the singular restricts the application of the process solely to the one mineral, pyrite. Of course, it is true that that mineral and sulphur are the ones commonly used, commercially, for the production of sulphur dioxide; but they are not the only ones.

Dana* lists 17 varieties of 'pyrites', among which may be mentioned, 'arsenical' (arsenopyrite), 'cockscorn', or 'white iron' (mareasite), 'copper' (chalcopyrite), 'cruescent' (bornite, or erubescite), 'magnetic' (pyrrhotite), as being the more important, in addition to 'iron pyrites' (which term includes both pyrite and mareasite). All of these will yield SO₂ when roasted in contact with air; and, specifically, they have all (with the possible exception of arsenopyrite) also been utilized to some extent commercially for the production of SO₂, notably mareasite, and chalcopyrite, in addition to pyrite.

I quite appreciate your oft-expressed objections to over indulgence in plurals, but think that in this case the plural is justified and broadens the application.

WALTER W. BRADLEY.

Statistician and Curator,
California State Mining Bureau.

San Francisco, July 11.

['Pyrites' is not the plural of 'pyrite', the *ites* being a Greek termination meaning 'bearing', the word signifying fire-bearing. Therefore it is pronounced pie-rie-tees, not pie-rights. Modern mineralogy has accepted 'ite' as the usual terminal and pyrite has been introduced in compliance with the custom. It has the advantage that it gives a plural, whereas the old term pyrites has no plural form. Yes, there are several kinds of pyrite, but when the word is used alone it signifies the commonest pyrite, namely, iron pyrite; the others are copper pyrite, arsenical pyrite, etc.—EDITOR.]

*Dana, J. D. (revised by E. S. Dana), 'The System of Mineralogy'; 6th ed., 5th thousand, 1914.

An Unusual Copper-Lead Deposit

By W. L. Uglow

The M. & K. prospect is interesting geologically and mineralogically because of the unusual type of occurrence for this Province and of the remarkable association of copper and lead minerals. The following description is based almost entirely on my field-notes, and is published with the consent of the parties for whom the examination was made.

The property is situated about 15 miles in an easterly direction up Legate creek, which enters the Skeena river one mile west of Pacific on the Grand Trunk Pacific railway. See map. It is reached by a pack-trail leading from the railway directly to the property. The mineral showings extend from an altitude of 4100 ft. up to 4725 ft., along the southern side of the M. & K. ridge, which presents a fairly even slope of about 35° .

The geology of the deposit is simple. The country-rocks consist of a conformable series of lavas and volcanic fragmentals, among which brown amygdaloidal and porphyritic andesite and basalt, greenish-black tuff, and

at intervals for an inclined distance of 850 ft. in a southeasterly direction, which on a dip of 35° gives horizontal and vertical dimensions of 700 and 500 ft., respectively. There is no reason to believe that the limits of the mineralization in this direction have been reached.

The deposit is oxidized in places for a few feet below the surface, so that it is difficult to ascertain the average width of the zone, but an estimate of 2.5 to 3 ft. is believed to be safe.

The deposit is a replacement of what appears to be a

FIG. 1. THE PROSPECT

brownish tuff agglomerate are prominent. This series is believed to belong to the Hazelton group. Dikes and sills of quartz-porphyry intrude these rocks, and seem to be responsible for the formation of the ore-minerals.

The bedded volcanic rocks strike almost due north (magnetic) and dip about 35° easterly. This structure controls the topography of the mountain-side, which, therefore, becomes a dip-slope. The mineralized zone occupies a persistent horizon that lies immediately underneath the overburden over the main part of the slope and conforms closely in attitude to the contour of the ground. In an easterly direction this horizon disappears from view under a thick cover of the volcanics (Fig. 2). This zone has been followed and opened up to a slight extent

bed of tuff. The zone of mineralization is composed of two distinct parts: an upper hard silicified portion varying in thickness from eight inches to five feet, carrying disseminated chalcopyrite with some bornite and galena; lying directly on a lower soft mashed portion from a few inches to eight feet thick, consisting chiefly of broken decomposed rock and gouge, and containing angular lenticular and rounded masses of an intimate mixture of bornite, galena, and chalcopyrite. These masses vary in size from that of a walnut to pieces two or three feet in diameter. Below this lower mashed portion is a definite slickensided foot-wall.

The hard upper portion of the zone seems to be continuous in extent, but not of uniform thickness. The

lower portion containing the solid masses of the sulphides is discontinuous and is found chiefly in depressions in the foot-wall. Between these depressions the hard portion of the zone lies in contact with the smooth foot-wall. See Fig. 3.

The property is developed by 17 small open-cuts on various portions of the dip-slope and by two tunnels on the mineralized zone, about 50 ft. and 8 ft. long. In no case do the open-cuts penetrate the foot-wall, which is rarely more than 8 or 10 ft. below the surface. No work

at 4.8e.). The assay was approximately 18 oz. silver per ton, 30% lead, and 18% copper.

(2) Dumps. Over 50 tons of somewhat similar material now lies on various small dumps; and grab-samples from these indicate a metallic content approximately as follows: 3 oz. silver per ton, 11% copper, and 13% lead.

(b) Upper Silicified Portion.

Seven channel-samples taken at intervals across this portion gave gross values varying from \$6.50 to

FIG. 2. CROSS-SECTION OF THE M. & K. PROPERTY

FIG. 3. LONGITUDINAL SECTION SHOWING OCCURRENCE OF M. & K. ORE

has been done to ascertain the value of the upper hard portion of the zone; all the development has tended to discover and remove the segregations of high-grade material from the depressions in the foot-wall.

The grade of the ore is as follows:

(a) Solid Masses of the Lower Zone. Results obtained from

(1) Shipments. In 1916-17 about 125 tons was stripped from two or three of these depressions and sent to San Francisco. This shipment realized a net return of over \$100 per ton (silver at 72c., copper at 24c., lead

\$60 per ton (silver at 94c., copper at 19c., lead at 9c.). These values are largely accounted for by the copper content.

The following characteristics of the deposit are of especial interest, and are the reason for the presentation of this paper.

(1) The mineralized zone lies almost immediately beneath the grass-roots over a large part of the dip-slope. It has already been eroded from most of the western portion of the hill-side.

(2) There is little pyrite in the deposit. The chalc-

pyrite in both portions of the zone is of the dense compact type and is comparatively pure.

(3) The mineralogy of both portions of the zone is the same, although chalcopyrite is most abundant in the upper part, and bornite and galena in the lower part. The minerals of the upper portion are disseminated through a gangue of highly silicified rock; while those of the lower portion are in solid masses separated from one another by rotten rock and gouge.

(4) The bornite-galena association. The solid masses of sulphides of the lower portion of the zone occupy the basins of drag-folds between the hard hanging and foot-walls. See Fig. 3. The most persistent characteristic of these masses of sulphides is the intimate association of bornite and galena of a fine-granular structure, indicating simultaneous development. In places, this mixture is almost free of visible chalcopyrite, whereas in other places, veinlets and larger masses of chalcopyrite appear to ramify through the other ore-minerals.

The examination of polished surfaces of this material has revealed the fact that the bornite and galena, with minor amounts of sphalerite, appear to be of simultaneous formation; whereas the chalcopyrite undoubtedly replaces portions of the bornite. Covellite is the latest generation and cuts indiscriminately all of the above-mentioned minerals. Under high magnification the megascopically homogeneous bornite is seen to be filled with a quadrillage structure of chalcopyrite laths, which represent one of the early stages in the process of the replacement of the bornite.*

The origin of these masses of copper and lead sulphides of the lower portion of the zone was not satisfactorily worked out in the time at my disposal in the field, but the following represents the working hypothesis that was used:

Before the folding of the volcanic series into their present attitude, the two portions of the zone of mineralization were fairly uniformly distributed and persistent. The upper portion, being silicified, was competent compared with the lower portion, which probably consisted of bands or elongated masses of the intimately associated bornite, galena, and chalcopyrite, of tabular habit, formed as replacements in a relatively incompetent bed of tuff. This tuff bed is succeeded in depth by a bed of agglomerate. During the deformation, the foot-wall of the mineralized zone or the top of the agglomerate bed was dragged into a series of small folds, while the softer inter-bed was mashed and squeezed and forced to occupy those basins or portions of the lower folded bed, which did not come into actual contact with the hanging wall. During the mashing of the material of the inter-bed, the bands or tabular masses of bornite, galena, and chalcopyrite were brecciated, and are consequently now found as fragments surrounded by the mashed remains of the tuff. See Fig. 3.

This folding and brecciation of the material of the

inter-bed left it highly pervious; and in its present attitude it constitutes a collecting channel and zone for the rain-water falling on the hill-slope. The circulation of this meteoric water down this channel has resulted in the oxidation and alteration of portions of the sulphides. In places solid masses of malachite and azurite with limonite are found enclosing remnants of the sulphides, while ramifying through the dense mass of sulphides are narrow veinlets of covellite, evidently of meteoric origin. The almost complete absence of chalcocite of similar meteoric origin is a noteworthy feature.

IMMERSION in boiling water reduces the strength of concrete, regardless of age, of the duration of the period of such immersion (except long immersions of very 'green' specimens), or the temperature of drying, so long as this does not exceed 180 C. These conclusions were reached by W. J. Schlick, of the Engineering Experiment Station of the Iowa State College of Agriculture and Mechanic Arts. Tests indicate that oven-drying generally causes a slight reduction in strength, but that this effect is so much less than that due to immersion in boiling water as to be obscured almost wholly when the specimen is subjected to both treatments. These tests show that immersion in boiling water causes a greater reduction in 'green' concrete than in well-cured concrete, and that a long-time immersion in boiling water hastens the strengthening of concrete. They also indicate that this loss in strength is accompanied by a loss or gain in weight, depending upon whether or not the concrete is oven-dried before the immersion. As there is no apparent physical action which could produce any of these effects in the amount shown by these tests, it seems logical to conclude that their basic cause is chemical action, which is accompanied by physical changes. It is known that the hydration of cement is accelerated by moisture and heat, and that not all of the cement is hydrated under normal curing conditions. On the basis of these facts it seems possible that the loss in strength due to immersion in boiling water is due to a rapid hydration, or curing, of cement not previously hydrated; and that this furthered and accelerated hydrating action is accompanied by changes in volume which tend to break down the more or less rigid structure resulting from the earlier hydration. The results with 'green' specimens that were immersed in boiling water for long periods seem to bear out this explanation. All the specimens tested, both tile and laboratory specimens, except tile of three series of the Bureau of Standards tile, were made with cements commonly used in Iowa, and probably similar in composition. Because of this fact, these data do not show what the effects might have been had other cements been used, or the qualities of the cement which will cause these effects to be the largest. As stated previously, these tests were made primarily to determine the effects of different immersion and drying treatments in connection with tests of concrete drain tile. The results show that no specimen should be subjected to any test in which its strength is a factor, after it has been immersed in boiling water.

*A paper taking up the description and origin of this quadrillage structure will appear in the January 1922 issue of the 'American Mineralogist'.

Metal Mining in California

By Charles G. Yalcé, of the U. S. Geological Survey

Metal mining in California during the first half of 1921 has been even more depressed than in 1920. Owing to the low prices of most of the metals and the increasing cost of production many mines have shut-down and others have reduced operations. During the first six months of 1921 the United States Mint at San Francisco and local smelters and refiners received from the mines of the State \$7,362,294 in gold, or \$482,000 less than during the first six months of 1920, when the receipts were \$1,086,739 less than in 1919.

The silver received during the first half of 1921 by the mint, smelters, and refineries amounted to 1,235,820 oz., or 726,535 oz. more than in the first half of 1920, and the first half of 1920 showed an increase of 376,310 oz. over the same period in 1919. This is somewhat remarkable, for several of the large copper mines of the State, from which most of the silver produced in California has usually been derived, have remained closed in 1920 and 1921. The deficiency thus caused has been more than made up during the last two years by the silver and silver-lead mines, more of which have been producing than in the preceding 25 years or more. Most of these mines are in Inyo and San Bernardino counties. By far the largest producer of silver in the State is the Rand, in San Bernardino county, opened in 1919.

No signs of immediate improvement in gold mining in California can be seen. The cost of supplies has diminished somewhat, but wages continue to be a source of contention between the operators and the miners' unions. Within a few weeks two of the most productive deep mines of the State will probably be added to the number that are closed down. At one of the larger mines, which crushed more than 60,000 tons of ore last year, the cost of producing gold was \$19.15 per ounce, and this property has perhaps the best-equipped reduction plant in California, making a total recovery of 97½%. The decrease in output does not affect equally the deep and the placer mines. The output of the deep mines appears to be falling off about 16%, whereas that of the placers is falling off only 12%. The placer-gold output is kept up mainly by the dredges, which show little total loss, but other forms of placer mining are not so prosperous as formerly.

Unfavorable conditions exist not only at the gold mines but at those yielding copper and other metals. Most of the larger copper mines and nearly all the smaller ones are still closed down, as they were in 1920. The most productive counties are Plumas, Calaveras, and Shasta, in the order named. The largest producer in the State is the Engels mine, in Plumas county, which continues its large production in the face of adverse conditions. There

has been an increase in the output of both lead and zinc, due almost entirely to the mines in Inyo county, although some zinc comes from Shasta county.

The Butte & Superior Mining Co., of Butte, has acquired interests in the Shasta Zinc & Copper Co., at Winthrop, Shasta county, and has also bought the property of the Bully Hill mines. The experimental zinc-oxide plant of the Shasta company began operations in April. The Argonaut mine, at Jackson, Amador county, one of the big Mother Lode mines, which was pumped out after the fire and flooding, is again producing, but its neighbor, the Kennedy, remains idle. The Utica and Gold Cliff mines, at Angels, Calaveras county, after more than half a century of productiveness, have been closed down permanently and allowed to fill with water. The old Plumas-Eureka mine, at Johnsville, Plumas county, has resumed operations, and the Rainbow, at Allegheny, Sierra county, is to be re-opened. The Fremont Consolidated, at Amador City, Amador county, closed for several years, is being pumped out for exploration. The famous old Rawhide, at Jamestown, Tuolumne county, is being re-opened, and a new 1800-ft. shaft is planned for it. A new 10-stamp mill is being erected for the Kate Hardy, at Forest City, Sierra county, and another of the same capacity has been finished at the Finnigan mine, at Angels, Calaveras county. A mill is also being built on the Grit property, at Spanish Dry Diggins, near Greenwood, El Dorado county. The Virginia-Belmont Co. has resumed development on the Virginia mine, Coulterville, Mariposa county, formerly owned by the White Guleh Mining Co. The Ghost mine, on Railroad Flat, Calaveras county, is being re-opened. A new 100-stamp mill is under construction at the Cerro Gordo mine, in Inyo county. The Juniper mine, Hayden Hill, Lassen county, which was re-opened after a long idleness, has been running its mill steadily since February. The Blue Ledge copper mine, in the mountains of Siskiyou county, near the Oregon line, which has been producing copper without interruption since the War, has closed down, and the construction of the proposed \$50,000 electric power-plant has been indefinitely postponed.

The reminiscences of old miners as well as reports, official and other, of remains of the great bonanza in the bottom of the old Eureka or Hetty Green mine, at Sutter Creek, Amador county, idle for a great many years, induced certain prominent capitalists to pump-out and re-open the mine. After a year or two of work, pumping, sinking shafts, running drifts and cross-cuts, and extensive diamond-drilling in all directions, with the expenditure of about a million dollars, nothing of value was found, and the enterprise has been abandoned.

Combination Dip-Chart and Protractor

By W. E. Gaby

The form of dip-chart shown herewith was evolved for the purpose of preparing vertical geologic sections with ease and rapidity; its convenience has been amply dem-

onstrated. It has a number of advantages over the usual logarithmic form of dip-chart, chief of which are the reduction and simplification of drafting operations.

In this form of chart two systems of curves, superimposed upon protractor, form co-ordinate lines by means of which one may pick a point on the protractor that will determine the angle of apparent dip of a vein, or other geologic structure, upon a given vertical section. The co-ordinate lines are drawn for intervals of ten degrees, from which the lines for odd degrees may be interpolated. The real dips are registered on the circumference of ellipses tangent at the centre of the protractor. The horizontal angle between the strike of the

vein and the course of the vertical section is registered on a curve interpolated from those that extend from end to end of the centre or zero line of the chart. In the illustrative solution, the curve for a horizontal angle of 8° (or 12°) intersecting the ellipse for the real dip, 32°, gives the point which determines the apparent dip as 7° degrees (7° + in this case). But if the chart, the geologic plan or notes, and the section are all oriented with respect to each other as shown, the operations of plottings can be made with no other instruments than a pencil and parallel ruler. So arranged, a line through centre of protractor carried parallel to the strike of vein gives the horizontal angle with the section. The value of this angle is noted. Then, in combination with the angle of real dip of the vein, one finds the point of intersection of the corresponding curves on the chart. The edge of the rule is then placed on the line between this point and the centre of the protractor, which line, carried parallel into the section, gives the apparent dip required, or, in other words, the trace of the vein on the section. The latter operation obviates the necessity of reading this angle at all, or of using a separate protractor to plot it.

In entering the chart, one must choose the side (upper or lower) that will resolve the apparent dip in its proper direction. The chart is more nearly precise for low angles, but it is sufficiently accurate in all ranges for geologic correlations; when either real dip or horizontal angle approaches 90° the variation of the apparent dip is small.

GRAPHITE is found in Ceylon in greater abundance than in any similar area in the world, states a consular report. The soil and rocks are almost everywhere impregnated with graphite, so that it may be seen covering the surface in the drains after rain. The supply is practically inexhaustible. Ceylon graphite is remarkably pure. The principal mines in Chosen, Korea, are in North Pyengan, North and South Choo-Chung, North Kyungsang, Kwangwon, and South Hamkyung provinces. Graphite is found in Hunan, China, on the Upper Mekong; it also exists near Wenchow (Chekiang), and in Kwangtung, in Kaotzu, west of Chingkiang in Kiangsu.

Future of Mining in Alaska

By Alfred H. Brooks

*The Alaskan mining industry, which has turned out products having a total value of \$438,160,000, began in 1880 with the recovery of some \$20,000 worth of gold from placers near Juneau. Of this total value, 96% is to be credited to the gold and copper deposits, but Alaskan mines have also produced silver, platinum, palladium, tin, lead, antimony, tungsten, chromite, coal, petroleum, marble, gypsum, graphite, and barite; development work has been done on deposits carrying nickel, iron, molybdenite, and sulphur.

The exploitation of Alaska's mineral wealth before the War showed a steady growth, with some fluctuations from year to year, such as are more or less inherent to mining in remote regions. This advance was made in spite of the handicaps imposed by isolation, the inadequacy of means of communication, and the long existing interdiction on the development of the coal- and oil-fields. Then came the change of industrial conditions wrought by the War. Its first effect was to increase Alaska's output of copper; this increase in 1916 brought the value of the total mineral output of Alaska up to over \$48,632,000, a larger amount than that for any other year since mining began. The decline in price and market demand for copper since 1916 and the world-wide depression of the gold-mining industry has greatly affected Alaska. As a consequence the value of the total mineral output of the Territory in 1919 was only \$19,621,000, as compared with \$28,254,000 in 1918.

This marked decline has been noted with alarm by many who are interested in the Territory and has been especially disconcerting to the general public, because it came at a time when Government funds were being expended on a railroad intended primarily to open up the mineral resources of the interior. This decline is not due primarily to local causes, however, but is largely the result of world-wide industrial conditions brought on both by the War and by the readjustments that have followed it. It is pertinent to inquire what the future holds forth for Alaska mining. If it is true that the decline in output is due to the general instability of industrial conditions, recovery must await the improvement of these conditions.

Although many local factors affect the future of the Alaskan mining industry, the most important consists of the mineral reserves. Unless the accessible reserves are large enough to support a future growth, the mining industry, no matter how favorable may be the conditions of exploitation, will languish. Those who have inquired about the quantity of mineral reserves have usually received the stereotyped answer that Alaska has vast stores of mineral wealth awaiting development. However true this may be, the public has a right to know on what facts such statements are based. An attempt will be made here to summarize briefly these facts, and to forecast, so far

as may be, the future of Alaska as a producer of minerals.

Before considering the future of the mining industry, it will be desirable to examine briefly the record of the past. The statistics of mineral production for the last 40 years are given in a later section of the report. Curves, though recording fluctuations from year to year, show on the average a uniform growth of output until the outbreak of the War in 1914, since when Alaska's mining industry has been unstable. If the pre-war curve showing the value of Alaska's total mineral output is projected over the last five years, it will indicate that under normal conditions the value would have been about \$22,000,000 in 1919. It is significant that the actual value of the output in 1919 (\$19,621,000) was only about 10% below this normal value indicated by the curve. This in itself is very encouraging, for it indicates that the Alaskan mines are on an average nearly holding their own, in spite of the present adverse conditions.

The pre-war curves might, of course, be projected also into the future, with a view to thus obtaining a rough estimate of the probable developments of the Alaskan mines. Such an estimate would have little value, however, because the mineral output of the past does not indicate the changes that will be brought about by the construction of the railroad and wagon roads, the reduction in freight charges, and the opening of the oil- and coal-fields. Moreover, such an estimate would assume, without proof, that Alaska's mineral reserves are ample to support a growth of the mining industry in the future at the same rate as that of the past. The quantity of the several minerals occurring in Alaska is evidently the significant element in the problem. In discussing these reserves it will be desirable to limit the estimate to those which are now or can soon be made available.

An estimate of Alaska's mineral reserves would be difficult enough even with complete geologic maps of the entire Territory. Only about 20% of Alaska has been covered by even reconnaissance geologic surveys, and less than 1% by detailed surveys. This meagreness of geologic data is in a measure offset by the fact that the area surveyed covers much of the immediately accessible parts of the Territory, where the most extensive mining developments of the near future are to be expected. The information at hand, however, at best does not permit quantitative estimates of reserves. Nevertheless, it indicates the areal distribution of the mineral deposits, and a study of their geologic occurrence gives a basis of forecasting their availability to the miner. These data, considered in connection with the accessibility of the deposits and the probable market for their output, will afford a rough measure of their availability in the near future. The production of placer gold has been founded principally on bonanza mining; lode mining has been supported chiefly by the large-scale exploitation of low-grade ores. The tendency of bonanza mining has been to cause considerable fluctuations in the annual gold output, but these fluctuations have, in a measure, been offset by the steady production of the large Juneau mines.

Book Reviews

Writing English Prose. By William Tenney Brewster. 16vo. Pp. 260. Published by Henry Holt & Co., New York. Price, \$0.90.

This is another aid to the correct writing of our language. The author is Professor of English in Columbia University; he writes therefore not only as one having authority but as a practised teacher of the subject. It is a winning little book; at least, I found it so; for the opening sentence did not please me at all and in the first chapter I found several departures from good writing; yet I continued to read, marking fewer and fewer passages to which I could take exception, until I finished the last page regretfully. A writer on 'writing' is subject to severe criticism, inevitably, and the reviewer of a book on such a subject is likely to be on the alert for blunders and infelicities of expression, but those for whom such a book is chiefly intended will approach it in a less exacting spirit and therefore miss some of the minor faults to which I have alluded. Some of them are due to the author's desire to avoid an excess of the pedagogic pose by descending to the use of colloquialisms or by lightening his admonitions with a touch of humor. These may detract from his style; but, after all, they are consistent with the fundamental rule of writing as he lays it down: "to write with your eye on the object", which some of us will change readily into the familiar admonition, "keep your eye on the ball". Professor Brewster says: "The great questions likely to be applied by anybody, at any time, to any piece of writing are these: 'Does it say what is intended?' 'Is it intelligible?' 'Is it said in as interesting and as agreeable a manner as is possible or necessary?'" The book stands this test; it is both interesting and agreeable. The author proceeds to say: "Writing, like talking, is nearly always directed to particular people or groups of people, to the end that they may be informed, or enlightened, or interested, or persuaded." In short, the fundamental rule of effective writing is 'Remember the reader'.

The first chapter discusses the principles of composition. "An inherent condition for expression in any language is progression. . . . Meaning is conveyed by a series of approximations; and, whether we think about the matter or not, we are, in all literary composition, bound to be progressives." A capital would have emphasized his point, for if he did not refer to the 'Progressives' he could have used the singular more satisfactorily. The idea of progression is a good one, "of progression from word to word, from sentence to sentence, from paragraph to paragraph". He expatiates on it most usefully in this chapter, which is rich in valuable advice. "The great condition of all communication, written or spoken, is intelligibility. . . . It is also a condition of communication that we put a good foot forward, that, in short, we try to be as interesting as possible. . . . Unless a writer conforms to the conditions of knowing his facts, his own mind, or what he wishes to say, he is likely to fall into all kinds of vagueness, obscurity, and error." Presumably the Professor deemed it pedantic to use the subjunctive after "unless"? "Clearness is, in a sense, truth. . . . Even if our ideas come pell-mell, they have to be recast for human consumption; otherwise we may get intellectual indigestion or spiritual strangulation. . . . Ideas do, as a matter of fact, spring from one another, are associated with and suggested by one another; a natural condition of working is to follow their lead." That is why so much writing is bad: it is disorderly simply because the writer fails to develop his ideas logically. "Any specific act of writing usually is the three-fold process of planning, writing, and revision." Many writers omit the first stage and consider the third unnecessary; hence the need for editing, of which there is not nearly enough, in books as well as in periodicals.

The author lays stress on 'conditions' rather than 'laws'. He favors freedom of movement and is impatient with set rules of composition. "A writer is limited, not by rules, laws, and precepts of writing and of style, but by conditions; that is, as we have seen, by his ideas, his audience, and the character of the language. The more he knows about these the better he will write." Yes, indeed, but the so-called 'laws' of composition are like the conventional plays of whist, in so far as they are the outcome of long experience; it is well to observe them, after having ascertained the purpose of them. To attempt to write or to play whist by rule without a thorough understanding of the rules is to court disaster; it is stupid. The author says: "The so-called principles of composition are useful only because they are sometimes conveniences of a more general sort. . . . The present tendency is, however, to use the word 'principle' in a technical rather than a moral sense. Thus unity, coherence, and emphasis are the group names for certain specific points that you may well keep your eyes open for when you read or write." A whist-player may have been born with card sense, and that innate ability would enable him to arrive intuitively at the correct plays, whereas one less fortunate in that regard would find it of great help to himself to be told the conventional rules; so an inexperienced writer, and one deficient in an innate ability to write, may be greatly assisted by being given a few 'rules' or 'principles' by which to guide his efforts to express himself intelligently and pleasantly. One of these is to avoid entanglement with prepositions, such as the "for" after "eyes open" in the preceding quotation.

At the beginning of his next chapter the author again develops his idea of progression: "Composition in literature is simply the art or the act of arranging the facts to be expressed in such a way as to bring out what is important; its object is to make clear or impressive the point or effect of any piece of writing. Order is, as we have seen, fundamental to good composition; but whatever may serve to make meaning clearer, to throw important facts into greater relief or to make them more interesting, belongs to the subject. In any event, literary composition, whether simple or intricate, depends on the structure of language; that is to say, it is essentially a method of progression, of accumulation, of piecing out idea with idea, of adding fact to fact."

In order to comply with "the inherent condition of all writing" it is necessary to examine the various ways of progression. There is time. Things happen in succession. Next comes cause and effect, the one necessarily coming after the other. Many things are "related to each other by position. . . . There are recurrent facts, and the recurrence may be in uniform order. . . . A certain state or condition is the result of antecedent situations and conditions and will lead to further conditions, so that our progression may take the form of looking back to a previous condition or looking forward by way of prophecy." The author elaborates this basic idea further, thus: "Two interesting types of progression—further refinements, if you will, on the main types—may be called composition by thesis and composition by prevailing mood. So far as these methods differ from the preceding it is in this: that not all the facts in a subject or a large or small body of interesting facts are ranged one after another, until the facts as facts are sufficiently aired, but that specially selected facts are made to illustrate and enforce special ideas and modes. On the central idea the facts are, so to speak, strung in the most effective and enticing order."

He gives a nice rhetorical touch to all this by concluding: "Structurally the thesis is the fork or spit which toasts the facts before the fire of genius." Coming to earth again, he repeats: "The process of composition is (1) a matter of classification of facts and (2) the ensuing arrangement of groups or divisions in the most effective order".

Good composition calls for unity, coherence, and emphasis. "The best way to gain unity," says the author, "is not to think about it, but to think of a subject till you know what you think and wish to say about it; and having done thus, to adopt as uniform a basis of treatment as may be, with due regard to the frailty of the reader." Yes, with constant regard for the reader, whether he be frail or robust. Coherence is "another way of saying that the facts in a piece of writing must be intelligently classified". Professor Brewster recognizes that Huxley was "a master of expository method" and instances the lecture on 'A Piece of Chalk', which is a fine model indeed for scientific writers. Emphasis in composition, he proceeds to say, requires "that important ideas shall be given important treatment". Referring to Stevenson's writings, he says: "The application of the so-called principles of composition is here obvious: unity means a careful selection of material and the removal of all husks that would clog movement; coherence, an arrangement of plot with as few hitches as possible; emphasis, elevating of important and the slighting of irrelevant matter."

A chapter is given to 'Narration, Description, and Exposition'; another to 'Argumentation'; and another to 'Paragraphs'. Each of these contains many valuable hints. The author is averse from positive dicta, however. For example: "We may say that there should be order in the sequence of ideas and sentences; that a paragraph may not unreasonably fulfil, in some way, the promise of its topic; that it is sometimes convenient to balance one part of a paragraph against another by a series of antithetical sentences, as frequently in Johnson, or by a formal opposition of beginning and ending, as sometimes in Macaulay, or by a topic set in opposition to the rest of the paragraph, as with many of our modern paradoxical writers who are masters of the formula, 'It is usually thought—But the truth is'. Everything depends on what one has to say, but, under that restriction and so long as there is some kind of order, any one of many arrangements may be about as good as another." Next we come to 'Style', to which five chapters are devoted under the sub-headings of 'Sentences and Words', 'Correctness', 'Economy and Increment', 'Pure Movement', and 'Composition'. He treats this part of the subject, as he does the remainder, in a businesslike way, without rhetorical confectionery. Style of writing to him is merely "manner of writing". He adds: "Over and above intelligibility, which is the natural aim of all language, style, as a special result, is conceived to be an expression of personality, of individuality, of 'the writer's sense of fact' ". To teach style, therefore, is impossible. "It is as idle to give instruction in the art of expressing individuality, of being oneself, of joining the chosen band of the naturally gifted, as it would be to attempt to teach youth how to become self-made men." He gives many examples and analyzes them carefully. He mentions reading aloud as the test of good movement in prose. Undoubtedly it is a good test not only of the quality he mentions but of writing in general, and it is one that the student should not fail to employ for the betterment of his method. In the last chapter, on 'Methods and Applications', after discussing the methods of sundry famous writers, we find this conclusion: "Practice is evidently very diverse; the only really constant thing is apparently that most writers of eminence have, at some or all points in their career, felt the necessity of taking pains". I venture to emphasize the last four words, for in them is the sum of the matter. Genius is said to be "an infinite capacity for taking pains". Another definition says that genius is one part inspiration and nine parts perspiration. Good writing comes from innate talent cultivated by patient practice. I have quoted enough from this book to indicate its style and character. Professor Brewster has produced a useful book. It may lack literary charm, for that is rare in the treatment of such a subject; and his own writing may not be impeccable, for that is

human; but the book fulfills its purpose as a friend to those who desire to improve their own writing or to teach the difficult art to others.—T. A. R.

Recent Practice in the Use of Self-Contained Breathing Apparatus. By Rex C. Smart. J. B. Lippincott Co., Philadelphia. Pp. 242, ill. For sale by 'Mining and Scientific Press'. Price, \$6.50.

The author, who during the Great War was the officer in charge of the First Army Mine Rescue School of the British Expeditionary Force, takes advantage of the experiences gained in training men and in organizing companies for mine-rescue work; he shows, with the extension of mining operations on the Western front, the depth to which mining was carried out, and, considering the large amount of explosives used, the necessity for the employment of mine-rescue apparatus. Plans of mine galleries that are reproduced will give an idea of the extent of underground work. With the organization of mine-rescue work, greater protection was afforded to the personnel of mining units; lives were saved, and gas poisoning was greatly reduced. The book is sub-divided into the following subjects: I. Organization of Mine-Rescue Schools. II. Training of Personnel of Mining Companies. III. Self-Contained Breathing Apparatus. IV. Testing and Repairing of Apparatus. V. Formation of Characteristic Mine Gases in Military Mining. VI. Resuscitation From Mine-Gas Poisoning. VII. Organization of Mining Companies in Mine-Rescue Work. VIII. Rescue and Recovery Work in the Trenches. IX. Use of Breathing Apparatus in Mine Warfare. X. Care of Mice and Canaries. Bibliography. Index.

The Location, Grading and Drainage of Highways. By Wilson G. Harger. New York, McGraw-Hill Book Co., Inc. 294 pp., 6 by 9 in., 134 illustrations. For sale by 'Mining and Scientific Press'. Price, \$3.50.

The author, who was formerly the senior highway engineer, U. S. Office of Roads, discusses the general principles that should govern the policies of highway engineering. The book considers a suitable system, appropriations, estimates, principles of design, and other pertinent matters. The questions of economic location and grade-line design are developed from the standpoint of horse- as well as motor-traffic. The treatise is the first of a series of four volumes on the subject; other volumes will deal with the selection of type of pavement, methods of construction and re-construction, and detail methods of field and office work. The contents of the present volume are: I. General principles of highway design. II. Proportion and economy in design. III. Classification, route and general engineering location. IV. Grades and alignment. V. Cross sections of rural roads; widths of pavements; right-of-way clearing. VI. Drainage; appendix; highway bonds.

Field Mapping for the Oil Geologist. By C. A. Warner. John Wiley & Sons, Inc., New York. 146 pp., ill. For sale by 'Mining and Scientific Press'. Price, \$2.50.

In the preparation of this book it has been the author's aim to furnish a handbook of field methods that would be of value to those geologists who have had little experience with the methods commonly employed in examining a territory not yet drilled. Only the important phases of field mapping have been considered. The reader is given a general résumé of the more important principles, with the idea that a foundation may be laid upon which detail work can be added. The book is divided into five chapters with the following headings: Study of Field Conditions; Maps, Their Value and Interpretation; Field Mapping and Methods; Field-Mapping Instruments, Their Use and Adjustment; Useful Tables and Meridian Determination.

REVIEW OF MINING

HAYDEN BILL ON CLAIM ASSESSMENT WORK PASSES HOUSE AT WASHINGTON

The House of Representatives has passed the bill, introduced by Representative Carl Hayden of Arizona, providing that the 'assessment' year for unpatented mining claims shall begin and end at 12 o'clock noon on July 1. Indications are that the bill will pass the Senate at an early date. This has no bearing upon the work for the year 1920, which became delinquent if not started before July 1, 1921. The new bill applies only to the future.

COPPER AND BRASS RESEARCH ASSOCIATION IS ORGANIZED

The Copper & Brass Research Association, a voluntary unincorporated body, has been organized in New York by producers of copper and fabricators of copper and brass. A campaign has been initiated to obtain as many members as possible. W. S. Eckert, secretary, in a communication sent to copper companies and others who may be interested, says: "With the copper-producing industry highly developed, we have not yet realized the full benefits from such development, for effort has heretofore been directed to the advancement of the individual without exploiting the wonderful properties of copper. Business conditions now prevailing, with the centralized control of the merchandising of many of the materials in competition with copper and its products, makes apparent the absence of concerted action by the copper and brass industry to win the ultimate consumer. And in reaching the ultimate consumer we have a problem too great for any individual member to solve; in its solution, through a united effort, each producer and fabricator will benefit."

NEW BILL ON WAR MINERALS RELIEF

John E. Raker, Representative from California, has introduced a bill before Congress to extend the provisions of the War Minerals Relief Act, incorporating practically all the amendments to the original bill which are understood to have received the approval of the Interior Department. Mr. Raker's bill extends the original act for the benefit of claimants whose cases have been disavowed through minor filing discrepancies. Additional authority is granted the Secretary of the Interior in the matter of reconsideration of claims upon which awards have already been made, and the unexpended balance of the commission's appropriation is continued available.

EXPORTS OF MEXICAN PETROLEUM DECLINE 80%

In the first two weeks of July there was exported from Mexico 1,645,000 bbl. of oil. This is at the rate of 3,300,000 for the entire month and compares with actual exports in June of 17,600,000 bbl., a reduction of 14,300,000 bbl. In short, based on figures of actual exports in the first half of July exports for the current month will show a reduction of over 80% compared with June. In all probability, too, the final figures for this month will not measure up to 3,300,000, for during the first four or five days of each month there is always a surplus of oil from the preceding month which it was impossible to get out. This reduction is due

in part to the export tax imposed by the Obregon government, and in part to the large surplus stocks in the United States.

THREE NEW GOLD-DREDGES TO BE BUILT AT MARYSVILLE, CALIFORNIA

Announcement that the Yuba Manufacturing Co. has secured contracts for the building of three gold-dredges with an aggregate value of more than \$1,000,000, was made at Marysville, California, on July 30, by Newton Cleveland, manager for the company. One of the dredges will be built for a company operating on the Tuolumne river. The others will go to Idaho and Colorado. "Securing of these contracts will mean much for the community," said Cleveland. "We shall employ immediately from 150 to 200 men and keep them busy for more than a year."

U. S. SMELTING CO. RESUMES MINING AT EUREKA, UTAH

Operations have been resumed by the United States Smelting, Refining & Mining Co. at its Centennial-Eureka and Bullion-Beck mines at Eureka in the Tintic district, of Utah. These properties are among the oldest producers in this district. For many years the Centennial-Eureka was the largest producer in camp, and the Bullion-Beck has been a consistent shipper since the early days. When the properties closed down early this year, 70 men were thrown out of employment, and it is expected that this number will again be on the payroll within a short time.

COMMISSIONER BELLOWES MAKES A PLAIN STATEMENT REGARDING GEORGE GRAHAM RICE

The following statement, signed by E. C. Bellows, Commissioner of Corporations for California, appears in the latest regular Bulletin issued by the Commission:

"Jacob S. Herzig, better known as George Graham Rice, has been heralded from the Atlantic to the Pacific seahoard as a stock gambler, a crook, a thief, and a jail-bird. Having failed to secure a license from the Commissioner of Corporations of this State, he floated Broken Hills mining stock through the San Francisco Exchange, leaving among the working people of this State, a trail of woe and distress as he headed for Utah to work new fields.

"In Utah he was the active spirit in financing the Bingham Galena Mining Co., and through Child, Barclay & Co., began circularizing his former victims in this State in behalf of Bingham Galena stock, which he claimed would recoup their former losses. In offering this stock for sale here without a permit from E. C. Bellows, Commissioner of Corporations, both Rice and Child, Barclay & Co. violated the Corporate Securities Act of this State, and if they desire to test the virtue of this Act, they have only to place themselves within the jurisdiction of the California courts where warrants await them.

"As was expected, the Utah Securities Commission has attempted to white-wash these offenders, but as far as the California public is concerned the effort will be unavailing. Any stock proposition polluted by the touch of George Graham Rice and his associates will be regarded with grave

suspicion in California. It has been stated that nothing was ever created in vain, but California investors incline to the opinion that the hand of Providence slipped a cog when George Graham Rice put in an appearance."

ARIZONA

Ajo.—The New Cornelia company is working two steam-shovels, employing 300 men, and treating 2400 tons of ore daily, six days per week. Production is running at the rate of about 1,300,000 lb. per month. It is expected that by 1923 New Cornelia will have a capacity for treating 10,000 tons of ore daily, as it is hoped to have the 5000-ton concentrator in operation by that time. This would result in a yearly production of at least 90,000,000 lb. of copper. The positive ore-reserves developed in the property amount to 8,641,000 tons of carbonates averaging 1.44% copper and 46,000,000 tons of sulphides averaging 1.53% copper. These reserves were determined by sinking 160 diamond-drill holes at 200-ft. intervals and to an average depth of 360 ft. Of this number, 27 were stopped in ore of commercial grade. In order to ascertain the results to be expected from the treatment of its large tonnage of sulphide ores (which do not respond to the leaching process) the company erected a 500-ton experimental oil-flotation concentrator which it operated for six months with satisfactory results. A shaft was sunk to a depth of 250 ft. and the sulphide body cut to provide representative ore for this plant. During its operation a total of about 25,000 tons of 1.3% ore was treated, with an average recovery of 85%.

Tombstone.—A report of uncovering larger and additional rich orebodies with high content in copper and silver was brought here recently by John W. Prout, Jr., superintendent for the Central Copper Co., of Mascot. The ore, found on both the north and south side of the hill, runs from 5½ to 20% copper and 16 to 19 oz. in silver. The extent of the ore-shoot has not yet been determined.

ARKANSAS

Yellville.—R. P. Templin, of Alton, Illinois, has purchased the mill equipment and leases on the Dixie Girl property in the Boat Creek district. The plant is among the most modern and complete in the Arkansas fields; it includes tramways for conveying the ore from the mine to the mills, which have a capacity of 150 tons. The property represents an investment of \$60,000. Tunnels into the mountain have disclosed an orebody 600 ft. in extent, most of which is high-grade carbonate ore averaging 40% zinc.

CALIFORNIA

Allegheny.—The Tightner and Sixteen-to-One mines are being operated on a two-shift basis, and the stamp-mills are operating regularly on medium-grade ore.—R. G. Gillespie and associates, of Pittsburgh, Pennsylvania, have purchased new machinery, preparatory to development of the Osceola property.—Work on a small scale is being done at the Rainbow, Mariposa, Morning Glory, Irwin, and a dozen other prospects.

Cofax.—J. Boggs, mine superintendent for a company that has leased the old Sim Jordan property, is ready to commence placer operations. The plans of the company are to divert the course of the American river for about a mile by the construction of a rock-bed tunnel, 6 by 7 ft. and about 1500 ft. long. In this manner the sand and gravel in the dry river-bed can be mined without interference from water.

Grass Valley.—The Gold Lead Placer Mines Co. reports that it has entered the channel with a raise 130 ft. from the adit-level. During the last nine months the company has driven 900 ft. of adit and has driven two raises to a total height of 260 feet.

Merced.—Creditors of the Yankee Hill Gold Dredging Co., recently adjudged bankrupt, will meet to determine the

disposition of their claims. The assets are a dredge costing \$100,000, and tools and equipment costing \$25,000. A flood last winter swept the dredge several miles down the river, and it is doubtful whether it has any considerable value other than for junk.

Oroville.—C. A. Miller, of the Foundation Co. of New York, expects to commence operations at Hartman's Bar above Cascade, on the middle fork of the Feather river. The company has completed a dam 137 ft. long, the water from which will generate 180 hp. The water will be pumped out and the gravel will then be handled by a clam-shell bucket.

Placerville.—With the starting of the new 40-stamp mill last week the old Havilla gold property near Nashville has resumed production. The mill is stated by the company officials to be one of the most modern in California. A large tonnage of good ore is ready for the stamps. The Havilla formerly ranked among the premier producers of the Mother Lode.

Winthrop.—J. R. Hall, supervisor of the Shasta National Forest, states that the fume from the new plant of the Shasta Zinc & Copper Co. has already had a noticeable effect upon the vegetation in the vicinity of the plant. It is claimed by the management of the smelter that any damage done to vegetation and gardens was due to hot weather and not to smelter fume. The fume is arrested in bag-houses, and no solid matter leaves the plant.

COLORADO

Cripple Creek.—The most important development at the Cresson mine since the discovery of the rich 'vug' in 1913 has been made in the north-western area of the Cresson estate beyond the crater at the 1700-ft., or Roosevelt tunnel, level. The ore-shoot as now developed on this level is better than 130 ft. long, with a width averaging 25 ft. over its entire length. The ore, shipped as broken, is returning between \$20 and \$40 per ton. The same shoot has also been opened up at the 1600-ft. level and as the ground above is virgin, it may carry through to surface. On the 1600-ft. level stoping has been commenced with the orebody holding its strength as in the deeper working. The shoot was originally found by diamond-drilling. The greatest value of the discovery is that it strengthens the prospect for other important discoveries in the same undeveloped area. The Cresson is shipping eight to ten cars of 30 to 35 tons capacity daily.

A fill on the old Florence & Cripple Creek railroad (now dismantled), near Hollywood, made from waste from the Strong mine at Victor, in the days of high-grade production from that property, when all waste was hauled by the railroad free under the 'right-of-way' contract, is now being hauled to the Independence mill of the Portland Gold Mining Co., where it is netting around \$10 and \$12 per ton. Under a contract, \$1 per ton was paid for the privilege of removing and shipping this rock.

Georgetown.—Operations are planned on the O'Connell group in West Argentine by Los Angeles operators whose representatives, Irving E. Bush and J. H. Harris, are on the ground.—The Arapahoe group in East Argentine is again active, with L. W. Vidler in charge.—Among other properties on which work is to be resumed in August is the Centennial, to be operated by the Indemnity company, recently incorporated.

Telluride.—The Belmont Wagner Mining Co., a subsidiary of the Tonopah Belmont company, of Tonopah, Nevada, has resumed operations at the Alta following 10 months inactivity. During the shut-down contractors were engaged in extending the Black Hawk tunnel to permit economical transportation of mill ores. The mill is now treating tailing. Sixty miners and millmen are employed, and, when

operating at capacity within the next 60 days, 200 additional men will be required.—The Suffolk mill is being overhauled and the Suffolk claims are being developed by the Summit Metals Mines Corporation.—The flotation unit of the Valley View Leasing Co., at the San Bernardino, is turning out a high-grade concentrate from San Bernardino mine ores.—Flotation equipment is being installed by the Matterhorn Mining & Milling Co., of which Park J. Dills is manager.

Ore of good grade has been opened at the mill-level of the Silver Bell at the Ophir loop. The property is owned by Wisconsin capitalists; operations on company account are to be resumed. The find was made by lessees.—The Smuggler-Union is operating its flotation unit with satisfactory results, and with other units completed the mill will have a daily capacity of 1000 tons.

IDAHO

Coeur d'Alene.—The Great Northern railway has an-

The property includes the Yankee Boy and Yankee Girl mines on Big creek. A 50-ton mill, equipped with ball-mills and flotation, is to be started. While the predominating value is silver, the ore contains some lead. Fifty-five men are employed in the mine and on the construction of the mill. W. F. Newton is superintendent.

Shoots of rich gray-copper ore have been uncovered in the Hecla. Stringers six inches wide have been followed for 25 ft. on the 600-ft. level; the assays show 1% lead, 16% copper, and from 95 to 500 oz. silver per ton.

The 200-ft. raise between the No. 1 and No. 2 tunnels in the Pilot mine on the North Fork has been completed. A vein on this property with a 'pay' streak next to the wall contains from five inches to a foot of ore exceedingly rich in both silver and gold, according to reports.

Night Hawk.—A mill of 50-ton daily capacity is being installed by the Four Metals Mining Co. on its property, three miles north of here, on the Shulkameen river. The plant will be equipped with two ball-mills, two jigs, five tables,

Eureka, Utah, Showing the Centennial-Eureka and Bullion-Beck Mines that Were Re-opened Last Week

nounced new freight-rates on ore and concentrate from Great Northern points to the Bunker Hill smelter at Bradley, Idaho, effective August 19. They should be of great benefit to shippers. According to Frank M. Smith, smelter director of the Bunker Hill company, the new rates, which make possible the shipping of ore and concentrate to the Bunker Hill smelter, are based on ore of \$30 value to the ton. Each increase of \$10 per ton in value up to \$100 is reflected in a 25-cent increase in freight-rates. To Nelson, B. C., the rate is \$3.75 for \$30 ore, increasing by 25-cent increments to \$5.50 for \$100 ore. To Libby, Montana, and to Porthill, Idaho, the rate is \$3.25 minimum and \$5 maximum. Salmo, B. C., Ymir, B. C., Boundary, and Republic all take rates of \$3.50 minimum to \$5.25 maximum. Troy, Montana, takes a rate of \$3 to \$4.75, Nighthawk, \$4.95 to \$6.70; Oroville, \$4.83 to \$6.60; Ruby, \$5 to \$6.75; and Tonasket and Okanogan, each, \$4.75 to \$6.50.

The Sunshine Mining Co. has shipped a carload of ore and is loading another. E. C. Tousley, general manager, expects to ship four carloads during July. Five were shipped in June, one of which contained 266 oz. of silver per ton and yielded \$4000 net.

and a flotation machine. It is expected to produce a concentrate containing 6% copper, 38% lead, and 60 oz. of silver per ton. The quantity of gold in the ore is small. The source of ore is a shoot six feet wide between walls and opened by a tunnel and a 100-ft. shaft. A depth of 300 ft. can be attained by the tunnel on the vein. E. Steffes, of Edmonton, Alberta, is manager.

KANSAS

Treece.—The Lennan mill has been entirely removed from its former situation near Commerce and is being re-built on the lease of the Waschusetts Lead & Zinc Co. in West Treece. J. H. Klinefeller, of Picher, has charge of the work. The mill will have a daily capacity of 350 tons. The field shaft-hopper and the tram to the mill have been completed and a 12-in. and a 14-in. pump are being repaired and installed.

MONTANA

Barker.—The operators of the Wright & Edwards property have 25 miners actively engaged in operating the mine; 1250 tons of ore assaying 35 oz. silver, and 40% lead is awaiting haulage to the railroad. Difficulty is experienced

in having a motor-truck road constructed, because of the fact that the mine is in Judith county, and Monarch, the nearest railroad point, is 12 miles distant, in Cascade county.

Butte.—Ex-Senator W. A. Clark has formally offered to underwrite the entire issue of \$1,000,000 in City of Butte bonds at par. On account of the inactivity of mining, city warrants had become unsaleable and the finances of the town were in a critical condition. Eastern bond-houses were disinclined to purchase the bonds. At this juncture Senator Clark came to the rescue.

NEVADA

Arrowhead.—The shaft of the Arrowhead is to be sunk from the present depth of 330 ft. to 600 ft. and a compressor and air-drills are to be bought for use in this work. It appears reasonably certain that building of a mill will be started in the spring.

Cherry Creek.—J. W. Walker, who is in charge of operations on the Mary Ann property, reports that the 800-ft. adit has cut the main Mary Ann vein. Drifting and cross-cutting is being done to determine the extent of the ore-body.

Divide.—The Tonopah Divide has resumed shipments to the Belmont mill at Tonopah, sending 35 tons daily, according to reports. It is said that 10 men are employed and that another shift is to be added.

Goldfield.—At a depth of 30 ft. in a winze from the 265-ft. level of the Red Top, the ore in the Silver Pick lease is 5 to 6 ft. wide and the average value for this width is \$80, according to Mat Murphy, superintendent. The shoot has now been opened for a length of 45 ft. and for 45 ft. on the dip of the vein. Two carloads of ore have been shipped, the average value being estimated at \$50 to \$70.—The shipment made by Donald and Giles, lessees on the Florence, had a net weight of 1727½ lb. and a net value of \$2287.77 per ton, according to returns from Selby. The metallic content was 146.10 oz. gold and 10.90 oz. silver per ton. The lessees are now loading a 50-ton shipment of \$150 ore.

Hornsilver.—The tenth carload of ore is being shipped from the Orlean. The winze being sunk from the 580-ft. level is 35 ft. deep.

Montezuma.—The 100-ft. shaft of the Harmill has been re-timbered nearly to the bottom. The shaft, formerly 3 to 5 ft. in the clear, is being enlarged to 4 by 7, and in doing this work a new vein, 8 in. wide, was found at a depth of 25 feet.

Round Mountain.—The report of the Round Mountain Mining Co. for 1920 shows a net operating deficit of \$15,932.78, caused by a short season for placer mining, the payment of \$30,000 for water-rights and pipe-lines, \$5000 for the purchase of stock in a mercantile company at Round Mountain conducted for the benefit of the employees, \$5233.24 for additional dam construction, \$2210.08 for a drill-sharpener, \$1422.64 for pipe and fittings, and \$8682.25 for personal property and bullion taxes. Most of the indebtedness is to the Fairview Round Mountain, in which the Round Mountain owns 20% of the issued stock. During the year 64,665 cu. yd. of placer gravel was hydraulicked, yielding 4292.26 oz. bullion, worth \$56,277.37, with \$818.78 received as royalty from placer leases. On December 31 the main tail-race was 5276.3 ft. long, lined entirely with 25-lb. rails. Lode mining was done by the company until June 30, 1920, and 4513 1 tons of ore of a gross value of \$23,475.29 was milled. On June 30 the company stopped work in the lode mine because of scarcity of labor and high costs. During the year lessees mined and milled \$67,351.89 worth of ore, net.

Tonopah.—The first semi-monthly clean-up of the West End Consolidated mill resulted in 26 bars of bullion worth

\$59,510. The increased output is attributed to the ore being shipped by lessees at the Halifax Tonopah and Mizpah Extension mines.—Thirteen bars of gold-silver bullion, having an estimated value of \$26,000, were shipped from the Tonopah Extension mill as a result of the mid-monthly clean-up in July. The company has put on another shift at the Victor shaft, and the work of unwatering below the 1760-ft. level is now under way. At the latest report, the water has been lowered to within about 50 ft. of the sump at the 1880-ft. level. When this has been accomplished, development and exploration work will be resumed at the bottom level of the mine.

The striking mine and mill workers voted recently to continue the strike. The West End employees continue to contribute \$5 to \$15 each monthly to support the strike, and the miners at Randsburg, California, report that they have sent \$600. Clyde Heller, president, and Frederick Bradshaw, general manager of the Belmont, are here. Heller declares that his company will not recede from its position and that there is accordingly nothing to arbitrate.

OREGON

Gold Hill.—The recent purchase of the Sylvanite group of gold mines three miles from Gold Hill by the Oregon-Pittsburgh mining company, indicates the increased activity in gold mining in this district. This is a new concern organized recently under the laws of Arizona with a capital stock of \$3,000,000; its headquarters are at Gold Hill and its main office at 307 Bessemer Bdg., Pittsburgh, Pennsylvania. The purchase price of the mine is announced to be \$180,000. Gold was first discovered on the Sylvanite vein, or, as it is known locally, the Big vein, 40 years ago when it produced high-grade ore near the surface. Later, in 1916, tungsten was discovered in the mine and since that time considerable importance has been attached to the property, due to that find. The tungsten is found with the gold ore in the form of scheelite. The mineral occurs in small stringers with quartz. Samples have been taken from these stringers which assay as high as 40% tungstic acid, but the veins as a whole average less than 2%. The veins carrying the best grade of tungsten have been developed to a small extent, but the tungsten resources of the mine have not yet been determined.

It was later in 1916 that J. G. Davies and associates of Sacramento, California, took over the property and in two years operation recovered about \$60,000, which was spent in developing and equipping the property. The mill equipment erected on the mine consisted of a 10-stamp mill with all auxiliary equipment for milling free ore. Early in 1919, Victor W. Brown and associates of Pittsburgh took an option on the property and have continued development with good results. The engineer in charge of the property, L. H. Van Horn of Gold Hill announces that the first unit of equipment for the reduction of the ores will be of at least 100-ton per day capacity. This applies to the treatment of both free-milling and base ores that are refractory and will require several processes. The Doan adit was driven on the vein at a depth of several hundred feet in the early history of the mine. It is advanced a distance of 1330 ft. This disclosed several bodies of high-grade ore. Work is now progressing through the Haff tunnel, which is a cross-cut tapping the Big vein at 650 ft. from the portal, and 65 ft. higher than the Doan level and 350 ft. below the surface. Several cross-cuts from the Haff level have opened good bodies of rich ore. About 120 ft. from the portal of the Haff adit a cross-cut was run north which at 28 ft. struck the Blind vein. A drift on the new find uncovered a body of rich ore. Continuing, this drift cut the Scheelite vein, so called because at the surface it yielded scheelite ore. At this point, however, it developed into a well-defined quartz with high-grade gold ore with the scheelite but little in evidence. The accompany-

ing photograph shows the mine and mill on the hill beyond the river.

Two miles south of the town of Gold Hill is the Braden mine. This property has been worked intermittently since the early 'sixties. Just south and east of the Braden mine are the Centennial, Millionaire, Roaring Gimlet, and Gold Ridge mines, all of which have passed through the same experience as the Sylvanite, but are now being put in operation again with the idea of mining deeper. Just across the ridge from the Braden on the west are the Bill Nye, Kubli, Red Oak, Tin Pan, and other smaller mines which have been the principal producers of this district and are still closed.

The recent reported uncovering of a large body of cinabar ore, in the David Force quicksilver mine, which assays from 40 to 60% mercury is reported.—The War Eagle company has developed ore containing, in addition to mer-

The Trojan Mining Co.'s payroll is larger than it has ever been in the history of that company. It is producing \$50,000 worth of gold each month and will probably increase this output. The acquisition of other valuable properties by purchase directly adjoining the properties of the Trojan company will probably result in adding to the mill.

UTAH

Alta.—Conditions at the Alta Tunnel & Transportation Co.'s property are reported as being the most favorable since development was started, according to F. V. Hodfish, manager. Raise No. 1, started at the intersection of the main fissure with a cross-vein, has cut a streak of high-grade silver-lead ore 8 in. thick. A bedded deposit of manganese, 20 to 25 ft. thick, has been cut by No. 3 raise. This bed overlies a stratum of low-grade ore, approximately 25 ft.

The Sylvanite Mine Near Gold Hill, Oregon

cury, large quantities of arsenic, some gold, silver, nickel, and zinc. Before resuming the company purposes to install equipment in its plant to recover several of the by-products.

Jacksonville.—The old Norling gold-quartz mine three miles west of Jacksonville on Jackson creek has been acquired by the Medford Mining & Milling Association, recently incorporated under the laws of Oregon. Recent work in the mine has uncovered a large body of ore assaying \$9 to \$18 per ton. During the first development of the mine in 1905-'07 it is reported to have produced 120 tons of ore worth \$6400.

SOUTH DAKOTA

Lead City.—The Homestake Mining Co. is employing approximately 2500 men. It is producing \$500,000 monthly in gold. A new hoist, one of the largest in the world, has been installed at the Old Abe shaft, thereby increasing the output from the lower levels. The Old Ellison hoist has been electrified, but is not in operation as yet. The company now is constructing a new 1000-ton mill in East Lead which will be equipped with a new type, 1700-lb. stamp. Each stamp will be capable of grinding from 8 to 10 tons of ore, whereas the company is now using in all the mills a stamp weighing about 900 lb., which will reduce only from four to five tons per day. When the new mill is completed the daily capacity will be increased from 4200 to 5200 tons.

thick, containing bunches of high-grade carbonate silver-lead ore.

Eureka.—Ore shipments for the week ending July 23 totaled 156 cars, the same as for the preceding week. The Tintic Standard shipped 51 cars; Chief Consolidated, 36; Iron King, 14; Iron Blossom, 12; Victoria, 11; Dragon, 10; Eagle & Blue Bell, 7; Swansea, 4; Gemini, 3; Colorado, 3; Mammoth, 3; Eureka Mines, 1; Sunbeam, 1.

The shaft at the Diamond Queen Mining Co. has been re-timbered, and announcement is made that work of deepening the shaft will be undertaken soon. It is the intention to sink the shaft to the 500-ft. level, where drifting will be undertaken.—A new find was recently made in the Iron Blossom mine of the Knight companies, which appears to have great possibilities. The Dragon mine, also controlled by the Knight interests, is now outputting a large tonnage of iron ore.—The heading on the 500-ft. level at the Eureka Lily mine has been in ore for the last 60 ft. The material is low-grade, with high-grade seams throughout the mass. The drift on the 1400-ft. level has been cutting bunches of high-grade silver-lead-copper ore, according to Grant H. Snyder, manager.

Park City.—Ore shipments will be resumed shortly by the Naildriver property, according to J. D. Fisher, superintendent. A small quantity is being mined daily; the work

that is being done by lessees is progressing satisfactorily. —Progress is being made in the erection of the new concentrating plant by the Silver King Coalition Mines Co. The steel-work is being set up as fast as it arrives, and about 70 men are now employed on mill-construction.

Shipments of ore from this district for the week ending July 23 totaled 1273 tons, as compared with 1475 tons for the preceding week. The Silver King Coalition shipped 565 tons; the Judge allied companies, 390, and the Ontario, 318.

Price.—The Raven Mining Co., owning elaterite properties in Duchesne county, has sold its holdings to the Elaterite Varnish & Rubber Co. of Los Angeles. This company is preparing to develop the deposit. The elaterite is valued at about \$100 per ton and is shipped by motor trucks to Price, a distance of 75 miles. Most of the product is shipped to Los Angeles.

BRITISH COLUMBIA

Edgewood.—Basil Cortiana, principal owner of the Ram-pulo group, at Lightning Peak camp, has driven the adit 40 ft. since the beginning of July, and is within 35 ft. of its objective. A drift on the vein from the tunnel 100 ft. above has been driven 150 ft., exposing a six-foot vein of good ore.

Slocan.—The Silversmith Mines, Ltd., has issued its annual report for the fiscal year ended May 31, 1921. Expenditure, which included the acquirement of the Ivanhoe mill, mill-site, and water-rights from the Minnesota Silver Co., amounted to \$240,298, and made a considerable inroad on the cash surplus. The reconstruction of the Ivanhoe mill, erection of the aerial tramway, and other improvements that now are being made will still further reduce this surplus. During the year 15,585 tons of ore was mined, 134 tons of which was shipped in the crude state, the remainder producing 2021 tons of lead concentrate, which was sold, and 2090 tons of zinc concentrate, which is being stored pending the finding of a profitable market. The ore sales realized \$260,404, compared with \$205,996 in the previous year. The Ottawa mill has been started, and is said to be giving complete satisfaction. It depends entirely on flotation for concentration of the ore.

MEXICO

Durango.—American capitalists are interested in the purchase of the old Salida mine in the Velardena district, which was allowed to go by default. It has been re-located as La Providencial. This property was worked prior to the revolution, the ores being treated at the Torreon and Velardena smelters. The ores contain silver and lead. —The furnaces of the American Smelting & Refining Co.'s smelter at Velardena are being kept heated by wood as fuel to prevent them from freezing up and cracking while the plant was shut-down. —Some shipments are being made from the Velardena to the Torreon smelter by small independent shippers.

The Concordia group of four mining claims has been re-located by Plutarco Almiada, representing W. Dartling. They are located in the Tamazula district in the municipality of Topla and include the old Prieta mine which contains gold and silver ores.

Parral.—The San Francisco Mines Co. made a fair profit for its last financial year with the present small plant, but the drop in metal prices has produced small losses. It is, however, believed that when the new 250-ton plant is in operation, which should be the case from January next, fair profits will be made even on the present price level. Development is in a backward condition, but, pending the erection of the new milling plant, milling of ore from the reserves will be suspended and development pushed forward, so that by the end of the year the position should have improved materially in this respect. During the remainder of this year, moderate profits are expected to be made by re-treating the 43,000 tons of residue, on which all mining

and milling charges have already been paid, and also by milling certain carbonate ores from the upper levels not included in the ore-reserves.

Parral.—Pedro Alvarado, the former mine laborer who became a multi-millionaire by his discovery of rich silver ore on the ground that developed into the famous Palmilo mine, it is reported has just sold fifty-one of his mines to the Mexican Natural Resources Co., of San Antonio, Texas, for \$6,000,000 United States money. Alvarado came into public notice about 15 years ago, soon after his rise to sudden fortune, by offering to pay the public debt of Mexico. General Porfirio Diaz, who was president at the time, refused the offer. For many years Alvarado distributed large sums of money among the poor people of Parral by making a trip through the streets once a week, scattering silver coins as he went along. The mining properties which Alvarado has just sold are situated in the States of Chihuahua, Durango, and Sonora. It is the intention of the company acquiring these properties to proceed with the development as rapidly as possible and to that end there are already in the field a staff of field engineers consisting of C. C. Coulter, George C. Hinton, Ernest E. Underwood, and E. B. Bunte, who have a completely equipped laboratory in Parral and are engaged in making a survey and report on each of the properties.

Santa Rosalia.—The Compañia del Boleo, an important copper mining and smelting concern, operating in Lower California, according to Consul Bartley F. Yost, of Guaymas, is enlarging its smelter through the installation of a converter plant for the purpose of refining the matte and blister in its own plant, instead of shipping it away for relining, as has been done heretofore. The cost of the machinery and installation is estimated at about \$1,000,000 and the company has floated bonds to that amount. All the machinery was purchased in the United States. As the company owns a fleet of steamers it is intended to transport the copper bullion through the Panama Canal to New Orleans and Galveston, where it will be trans-shipped to New York. The company owns a tank steamer for bringing crude-oil from Tampico to Santa Rosalia. On its return trip it will be loaded with copper bullion.

Torreon.—Simon de Avila and associates of this district have recently located a group of six claims in the foothills of the Sarnosa mountains west of the city of Lerdo. Preliminary work on these claims has produced some good silver-lead ores. —Work is now being carried on at the Mapami mines of the Cia. Minera de Penoles and the ores are being shipped to their smelting plant at Torreon.

At San Juan de Guadalupe, a short distance south of this city, Eugene Leroy has taken over the Gardenia and Chabasco mines. These properties have produced considerable high-grade silver-lead ores and are again being put in shape to continue production.

Zacatecas.—General Rios Zertuche, associated with his brother, Dr. Daniel Rios Zertuche, has taken up a large group of claims in the Pinos district. The denouncement embraces a number of old abandoned mines which in former years produced large quantities of silver-lead ores which were shipped to the nearby smelters. The new title to this group is the Anexas a Tres Amigos. Development work is planned in order to put the old workings in shape for actual mining. —Clemente Vergara has also applied for titles to the La Luz group of mines in the Mazapil district. His filing has been recorded with the mining agent at Zacatecas city.

ONTARIO

Bourkes Station.—The mine buildings at the Bourkes mines were recently destroyed by a bush fire, causing a loss of about \$25,000. The mine had been closed for about a year.

Kirkland Lake.—The Lake Shore during June recovered \$52,539 from the treatment of 1656 tons of ore, being an average of \$31.64 per ton. The mill ran only 75.9% of possible running time, owing to power difficulties. Final arrangements have been effected for the re-opening of the Sylvanite. It was originally planned to include this mine in the merger, which resulted in the formation of the Kirkland Lake Proprietary (1919), but it was found difficult to secure control of the stock. It is now understood that J. G. Latilla of London has secured and exercised an option on stock held by William Wright, and effected a satisfactory arrangement with Buffalo stockholders identified with the Wright-Hargreaves for the development of the property. Albert Wende, general manager of the Wright-Hargreaves, will direct operations. The production of the Wright-Hargreaves for June exceeded \$51,000 in spite of the loss of nearly 25% of the possible running time due to the failure of the power company to supply electricity. Development work is being directed to opening the 200-ft. and lower levels. At the King Kirkland another vein from 7 to 10 ft. wide has been found on the surface. It is heavily mineralized. The drift at the 300-ft. level of the Bidgood has been in ore for upward of 100 feet.

Porcupine.—A new orebody discovered on the McIntyre by diamond-drilling has been cross-cut on the 1375-ft. level, where it shows a 30-ft. width of ore assaying \$20 per ton. The vein is supposed to have come in from the Hollinger, the boundary of which is several hundred feet distant. In the main shaft a station is being cut at 1625 ft. When this is completed the work of deepening the shaft to 2000 ft., with stations at 1750 and 1875 ft., will be started. At the Porcupine Paymaster the main vein is being driven on at the 200-ft. level with encouraging results. The vein is 20 ft. wide in places, with parallel veins of importance running in close proximity. The shaft will be deepened to 400 ft. The shaft of the Beaumont, formerly the North Davidson, is down 300 ft. and a station is being cut at that level.

SPAIN

Madrid.—The following decree regarding the granting of concessions for the exploration and operation of mines appeared in the 'Gaceta de Madrid' of June 15, according to a Consular report:

Article 1. On and after the date of publication of this decree in the 'Gaceta de Madrid' mining concessions will be granted only to Spaniards or companies formed and domiciled in Spain, it being required in the latter case that the president of the Council of Administration, the administrative delegates, the managing directors with the power of signing in the names of the companies, and the engineers charged with the works be Spaniards. Only one-third of the other offices may be held by foreigners. The above-mentioned concessions may not be ceded or transferred except to persons or entities fulfilling the stated requisites.

Art. 2. All concessions authorized will be under the condition that the material and machinery used in the exploration and operation of the mines shall be of Spanish production and manufacture, and that the use of foreign material and machinery will only be authorized in the case where it is shown, before the Commission for the Protection of National Production, that it is absolutely impossible to obtain them in Spain on account of their not being produced here.

The Government will make its decision without further recourse.

Art. 3. The present concessionnaires of mines and those being registered on the date of this decree will continue to enjoy the rights authorized by their concessions, and only in their new installations will have to comply with the conditions of the above article with regard to materials and machinery.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

A. N. Franchie was in San Francisco this week.

F. L. Sizer has returned from Grass Valley, California.

F. A. Voorhees, of Los Angeles, is at Mojave, California.

Augustus Locke is at Butte, on his way to Calumet, Michigan.

Henry S. Burholz has moved from Torreon, Mexico, to New York.

Robert B. Brinsmade has moved from Ixmiquilpan, in Hidalgo, to Mexico City.

Cornelius F. Kelley, president of the Anaconda Copper Mining Co., is visiting Butte.

Arthur Gibson is now with the Maxine Mining Co., at La Porte, in Plumas county, California.

C. G. Patterson has moved from San Juan de Limay, Nicaragua, to Piedmont, California.

E. J. Franklin, mechanical engineer for the Ray Consolidated Copper Co., is at Salt Lake City.

Frank D. Pagliuchi has left for New York. He expects to return to San Francisco in about a month.

John P. Benson, of Berkeley, California, is now with the Grecia Mines Co., at San Juan de Limay, Nicaragua.

Howard D. Smith is here from New York. He is about to examine a group of mines in Nevada county, California.

Forest Rutherford has returned to New York City after completing some mine examinations in Northern Ontario.

J. E. Robison was in San Francisco this week; he will sail from New York for the Belgian Congo in about a month.

George H. Bern, mining engineer of Salt Lake City, has returned home after a five weeks trip to New Mexico and Arizona.

A. W. Newberry has been employed by Weld & Liddell, consulting engineers of New York, to examine a mineral property in Montana.

J. O. Greenan, for the past year engineer in charge for the Keno Hill company, at Mayo, in Yukon Territory, has returned to his home at Berkeley.

Harold Cogswell has left the Idaho-Maryland Mines Co., at Grass Valley, California, and is now with the United Comstock Mines Co., at Virginia City, Nevada.

Charles F. Raney, formerly efficiency engineer for the North Butte Mining Co. and now with the E. I. Du Pont de Nemours company, is in San Francisco from Denver.

T. Horiuchi, director of the Meiji Mining Co. of Japan, and Y. Takahashi, chief mining engineer for the Tanaka Mining Co., are visiting mining districts in this country.

Chris G. Dobson, of the faculty of the College of Engineering, University of Washington, Seattle, is now doing special engineering work for the Gold Reef Mining Co., at Cornucopia, Oregon.

C. Minot Weld and Donald M. Liddell will continue to practise as consulting engineers and economists under the name of Weld & Liddell, at 2 Rector St., New York, the partnership of Weld, Liddell & Lazenby having been dissolved.

Olaf P. Jenkins is in charge of the field-work of the Washington Geological Survey, and is investigating certain road materials, the Grand Coulee as a reservoir site, and the iron ores of Washington in relation to the possible manufacture of iron and steel.

Frederick W. Denton, vice-president of the Copper Mining Co., has been appointed as a member of the Board of Control of the Michigan College of Mines at Houghton. He succeeds James MacNaughton, general manager for the Calumet & Hecla Mining Co., whose term has expired.

THE METAL MARKET

METAL PRICES

San Francisco, August 2

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	6
Copper, electrolytic, cents per pound.....	13.00—13.50
Lead, pig, cents per pound.....	4.05—5.05

Spelter, cents per pound.....	0.50
Zinc-dust, cents per pound.....	9

EASTERN METAL MARKET

(By wire from New York)

August 1—Copper is inactive and weak. Lead is quiet and steady. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

GASOLINE AND BUSINESS

A striking situation, and one having a most important relation to the general economic conditions throughout the country is shown in the unprecedented accumulation of gasoline stocks as recorded for the month of May, and the unexpected decline in consumption. For many years the curves of increases and depletions in the country's gasoline stocks have followed a normal course of increase in winter, continuing from October to April and a lowering of the curve from April to October. The reason, of course, is the starting each summer of maximum use of motor-cars and trucks, with a resultant lowering of storage stocks of gasoline, followed by a re-building of stocks in the winter months of minimum car use.

The present year, however, presents a remarkable departure from the normal trend in that there was a complete break in the normal rate of increased consumption in May. Month by month, the country had been using from 2,000,000 to 3,000,000 gal. of gasoline more per day in 1921 than in 1920. This continued in April of the present year. But in May the total consumption, including exports, was less on a daily basis than in the preceding April, and the country used 1,700,000 gal. per day less than in April 1920. On May 31, 1921, there was 800,000,000 gal. of gasoline in storage, which is the highest stock of record for the United States.

This complete reversal is a natural reflection of general economic conditions, both at home and abroad. There have been less exports and shipments to our insular possessions. During May the domestic consumption exceeded that of April by 21,000,000 gal., but the exports were 17,000,000 gal. less. Considering stocks as a whole, at the end of April 1920, there was 643,552,644 gal. on hand, while at the end of April 1921 there was 577,071,795 gal. on hand, or a running down of the stocks of about 70,000,000 gal. in May 1920. Quite different are the comparative statistics for the same month this year. On April 30, 1921, there was 747,222,000 gal. of gasoline on hand, and at the end of May there was 800,045,787 gal. on hand. In other words, instead of a depletion in the stocks of approximately 70,000,000 gal., as occurred within the same period in 1920, the stocks were actually built up by 53,000,000 gal. during May of the current year. The relation of consumption to the use of automobiles and trucks, while a matter of common knowledge, will be more definitely appreciated through figures showing the total number of such vehicles registered and the production of gasoline during the same years.

Year	Production of gasoline in millions of gallons	Automobiles and trucks registered in the U. S.
1920	4883	8,500,000
1919	3958	7,559,000
1918	3570	6,147,000
1917	2850	4,983,000
1916	2050	3,518,000
1915	1407	2,446,000

The answer to the anomaly of an increase in gasoline stocks in May, instead of a decrease, and a decrease instead of an increase in consumption as might normally be expected, is a decreased use to a very marked degree of automobiles and trucks in the United States during the month, as compared with the previous month, or with the corresponding months of previous years; also to a decrease in exports.

MONEY AND EXCHANGE

Foreign quotations on August 2 are as follows:

Sterling, dollars:	Cable	3.57
	Demand	3.58
Francs, cents:	Cable	7.72
	Demand	7.74
Lire, cents:	Demand	4.30
Mark, cents		1.25

Eastern Metal Market

New York, July 27.

Buying of all the metals is 'spotty', and prices in some cases are lower. There is no evidence of any revival and none is looked for before fall.

Necessity of sacrificing speculative lots has resulted in lower prices for copper, with light buying.

There has been some buying of tin at lower prices.

Demand for lead is moderate, but prices are unchanged.

There is little life to the zinc market, with values fairly firm.

IRON AND STEEL

Further settling of steel prices has come in the past week, and in some products the downward movement has been rapid, says 'The Iron Age'. Informal announcement of a 1.75c. price for steel bars and of 1.85c. for plates and structural shapes—a \$3-per-ton cut below the July 5 schedule—was made in the week by several independent producers, but already somewhat lower prices are reported, indicating more aggressive competition in practically all markets.

Some encouragement is found in the larger tonnage under inquiry, but it is well recognized that in such a market no approach to price stabilization is to be expected. Every producer is meeting competition as it develops.

That the Steel Corporation's earnings for the second quarter were better than most predictions is ascribed in part to its unique advantage in railroad ownership and the fact that, for nearly all the second quarter, Chicago business was done on the Pittsburgh base.

Operations by Steel Corporation mills are running close to 30% this week, an improvement over the previous July average. Railroad-car repair-work is gradually being arranged for. Railroad material inquiries continue to feature the international markets. In August 12,000 tons of rails are to be bid on for Chile and 3000 tons for Morocco. Some 12,000 tons will be bought for a new Bolivian railroad and 1000 tons of light rails are wanted in Manila.

COPPER

Buying of copper is not heavy and what there is is spasmodic and of an uncertain nature. It is confined, as to sellers, to speculators or small producers' interests who, for financial or other reasons, are obliged to sell as the month of July comes to an end. This situation has resulted in offerings of electrolytic copper at concessions under what most large interests are willing to consider. While reports are to the effect that some sales have been made as low as 12.12½c., delivered, for July-August, a fair appraisal of values seems to fix 12.50c., delivered, as the present market, with lots here and there available at lower levels. The large producers are maintaining one asking price of 12.75c., delivered, or 12.50c., New York, but would probably shade this on desirable business. The Lake copper market is inactive at 12.50 to 12.75c., delivered. Buying for foreign consumption is moderately good. There is active inquiry for casting copper from China, with some purchases recorded.

TIN

Outside of three moderately active days last week there has been little business. On those days it is estimated that about 500 tons of future shipment Straits tin was sold, both consumers and dealers being the buyers, the latter predominating. Later there were few sellers, and buyers also were disinclined to purchase, in the confident belief that prices would be lower this week. This has been realized, the market breaking quite sharply yesterday and Monday, the quotation yesterday having been 26c., New York, against 27

to 28c. the week previous. The market is now quiet and weak. There has also been a decline in London quotations, those yesterday having been £158 5s. for spot standard, £160 5s. for future standard, and £158 15s. for spot Straits, all about £3 per ton lower than one week ago. Arrivals thus far this month have been 1270 tons, with 2865 tons reported afloat. One seller feels strongly that there will be no revival of any consequence for a year now that the canning season has passed and evidence being fairly good of stocks of some proportions in the hands of consumers.

LEAD

It appears that the leading interest is able to meet the light demand that exists at its regular quotation of 4.40c., New York, which we quote as the market. The St. Louis quotation of the same producer is also 4.40c., but independent producers are quoting 4.35c. and taking such business as is offered in that market. The latter sellers, however, in New York, are not at present a factor and almost nothing is heard of any offerings in the outside market. The market may be characterized as very quiet and barely steady.

ZINC

One large seller characterizes last week as the most stagnant in his memory, there having been three successive days on which there was no inquiry of any kind. This week there has been more demand which has resulted in good sales, a few 100-ton and smaller lots of prime Western going at 4.25c., St. Louis, or 4.75c., New York. The 4.20c., St. Louis, offerings of last week appear to have been eliminated. The buying referred to has been mostly from galvanizers bare of stocks and able to operate on recent orders. 'Brass-special' is quiet and selling at 4.35 to 4.40c., St. Louis.

ANTIMONY

Wholesale lots for early delivery are obtainable at 4.65c. per pound, New York, duty paid. Offerings from the Orient are lower at around 4c. in bond, New York, which has resulted in a fair amount of buying of futures.

ALUMINUM

Virgin metal, 98 to 99% pure, is now quoted by the leading producer at 24.50c., f.o.b. plant, in wholesale lots for early delivery, with imported metal of the same grade available at 22 to 23c., New York.

ORES

Tungsten: A little business is reported consisting of odd lots, but while inquiry is a little better there is no activity. Quotations are unchanged at \$3 to \$3.25 per unit for good ores.

Ferro-tungsten: The market is without life and quotations are nominal at 48 to 58c. per pound of contained tungsten in lump form, guaranteed quality.

Molybdenum: A little inquiry is reported but quotations are nominal at 50c. per pound of MoS₂ in regular concentrate.

Manganese: There is absolutely no demand, with quotations nominal at 22c. per unit, seacoast.

Manganese-Iron Alloys: The markets for both ferro-manganese and spiegeleisen are stagnant and quotations are nominal. For American ferro-manganese the asking price is \$75, delivered, while the British price is \$70, seacoast, but it is acknowledged that these could be sharply shaded were there any demand. Spiegeleisen, 20%, can be bought as low as \$26, furnace.

Ferro-silicon, 50%, is quoted by leading sellers at \$65 per ton, delivered.

Current Prices of Commodities

The figures given on this page represent the regular current price, at the time of our going to press, to industrial buyers of standard commodities in small wholesale lots on San Francisco Bay. They should not be construed as being quotations nor as being either the lowest or the highest price; they are given rather as a guide by which to follow the trend of the market or to estimate the approximate cost of materials and supplies.

CHEMICALS AND ASSAYERS' SUPPLIES

Acid, sulphuric, com'l 66%, in drums, per 100 lb.	1.50 to 2.00
" " " " carboys " "	2.60 to 3.10
" " C. P., 9-lb. bottles, in barrels, per pound	0.23 1/2
" " " " bulk, in carboys, per pound	0.18 1/2
" muriatic, com'l, in carboys, per 100 lb.	2.75 to 3.25
" " C. P., 6-lb. bottles, in barrels, per pound	0.28 1/2
" " " " bulk, in carboys, per pound	0.22 1/2
" nitric, com'l, in carboys, per 100 lb.	9.00 to 9.50
" " C. P., 7-lb. bottles, in barrels, per pound	0.38
" " " " bulk, in carboys, per pound	0.27 1/2
Argols, ground, in barrels, per pound	0.14
Borax, cryst. and conc., bags, per 100 lb.	5.50 to 6.50
" powdered, in barrels " "	5.75 to 6.60
" glass, ground, 30 mesh, cases, tin lined, per 100 lb.	8.50
Bone ash, 60 to 80 mesh, in barrels, per 100 lb.	0.31
Cyanide, sodium, 96 to 98%, 100-lb. drums, per pound	16.00
Lead acetate, brown, broken casks, per 100 lb.	19.00
" " white " " "	0.20
" " " " crystals, per pound	17.50

Sockets, weather-proof, molded, No. 60,000, per 100	28.80
Telephone wire, iron, size 12, half-mile lots, per 100 lb.	10.25

EXPLOSIVES

Blasting-caps, No. 6, in lots of 5000, per 1000	17.00
" " " " electric, 0-ft., No. 6, in lots of 1000, per box of 100	8.73
Blasting-powder, "B" soda, in 100-kg lots, per keg of 25 lb.	2.10
Dynamite, nitro-glycerine, 40%, in ton lots, per 100 lb.	19.25
" " gelatine " " "	19.25
" " ammonia " " "	18.25
Fuse, common, in case lots, per 1000 ft.	8.50
" " waterproof, triple tape, in case lots, per 1000 ft.	10.54

FUELS

Coal, Utah steam, \$4 at mine, plus \$7.50 freight to California terminal points, in carload lots, per ton	11.50
Coal blacksmith's, in carload lots, per ton	24.00
" " " " in small lots, per ton	27.00
Coke, in carload lots, per ton	26.00
Fuel oil, per barrel	1.75
Diesel oil, per gallon	0.06 1/4
Distillate " " "	0.10 1/4
Gasoline " " "	0.24 1/2

HARDWARE

Anti-friction metal, per pound	0.24
Babbitt, genuine " " "	0.54
Brass sheets, half-hard and soft, per pound	0.28
Drill-steel, hollow, first grade, in ton lots, per pound	0.18
" " " " solid " " "	0.11
Fish-plate bolts, 3/4 by 2-in., per 100 lb.	0.30

Nails and spikes (20d to 60d base), per keg	4.75
Nuts, hot pressed, 3/4-in., hexagonal, per 100 lb.	10.75
" " cold punched " " "	12.30
Picks, mining, 5-lb., per dozen	12.00
Shovels, carbon steel, No. 2, long handles, per dozen	18.00
Track spikes, per 100 lb.	0.10

HEAVY STEEL AND PIPE

Bar steel, soft, per 100 lb.	3.75
Rails, steel, 8 to 25-lb., per 100 lb.	4.54
Reinforcing-steel, per 100 lb.	3.75
Sheets, corrugated, galvanized iron, 26-gauge, per 100 lb.	6.80
" " flat " " "	6.70
" " flat, black iron " " "	5.90
Structural 3"s, channels, angles, and beams " " "	3.85
A deduction of 15c. per 100 lb. is made on the above when purchased in carload lots.	
Bars, steel, square, cold-rolled, per 100 lb.	7.10
Pipe, wrought-iron, black standard, 1 1/2-in., per 100 ft.	13.30
" " " " galvanized " " "	16.70
" " " " black " 4-in. " "	58.00
" " " " extra strong " " "	113.75
Shafting, cold-rolled (2 1/4 to 3-in. base) " " "	5.50

HOISTING-ROPE

Discounts for delivery from Pacific Coast stocks are: cast-steel, 22 1/2%; extra strong cast-steel, 30%; plow-steel, 35%; blue-centre steel, 20%. The following illustrations indicate the net price for each kind of rope, in standard 6-strand, 19-wire, 1-in. rope.	
Blue-centre rope, per foot	0.40
Cast-steel rope, per foot	0.24
" " extra strong, per foot	0.26
Plow-steel rope, per foot	0.28

LUMBER

The figures given are subject to variation, depending upon the size and length. A charge for cartage is also to be added. Prices are furnished by Van Arsdale, Harris Co.	
Fir, No. 2 clear and better, 1 to 2 in. thick, up to 16 in. wide, per thousand feet (M)	90.00
Fir, common, base price, per M	30.00
Fir, common, 6 by 6-in. up to 12 by 12-in., per M	36.00
Redwood, rough merchantable, 1 to 4 in. thick, per M	50.00
" " clear, 1 to 2 in. thick, up to 12 in. wide, per M	100.00
Spruce, 'B' and better, 1 to 2 in. thick, up to 16 in. wide, per M	90.00
Sugar-pine, No. 1 and 2 clear, 2 in. thick, up to 16 in. wide, per M	200.00
White pine " " "	180.00

MISCELLANEOUS

Air-hose, 1-in., 5-ply, plain, per foot	0.48 to 0.65
Candles, 'Granite' mining, 6-16-40, 10-case lots, per case	6.40
Carbide, in 100-lb. cans, per can	7.75
Cotton waste, best grade, per 100 lb.	14.00
Diamonds for drilling, according to size, per carat	50.00 to 75.00
Manila rope, grade 1, per pound	0.15
" " " " 2 (standard), per pound	0.14
Packing, flax, per pound	0.38 to 0.90
" sheet " " "	0.35 to 1.00
" steam or water, first grade, per pound	1.00
Silex lining, erated, per long ton	35.00
Tube-mill pebbles, Danish, selected (in bags), per long ton	30.00
Zinc-dust, in 250-lb. boxes, per 100 lb.	9.00
" sheet, 36 in. by 84 in., in ton lots, per 100 lb.	14.00

PORTLAND CEMENT, LIME, ETC.

Fire-brick, clay, per 1000, in carload lots	60.70
Fire-clay, in bags, per ton	18.00
Lime, lump, in barrels, per barrel of 180 lb.	3.25
Portland cement, in bags, per barrel of 380 lb.	4.20
Allowance of 15c. for bags returned in good condition.	
Portland cement, in barrels, per barrel of 400 lb.	5.50
A deduction of 50c. per barrel is made on lime and cement when sold in carload lots.	

ORES AND MINERALS

The following prices represent approximately what can be obtained for the products indicated delivered at points on San Francisco Bay. These, of course, vary widely with the grade and purity of the ores. The present stagnant condition of the market makes many of the quotations purely nominal; most of the ores can be purchased at these prices, but it should be understood that it is not easy for the producer to market them at this time.	
Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per %	00c.
Asbestos (crystalline), according to length of fibre, per ton	\$20 to \$2500
Barite, white and free of iron (crude), per ton	5 to 10
Bismuth ore, not less than 20% Bi, per % Bi	12
Feldspar, crude, lump, free of iron, per ton	5 to 10
Fluorspar, 85% calcium fluoride, per ton	15 to 20
Fuller's earth, ground to pass 80-mesh, per ton	5 to 10
Graphite, crystalline, per pound	3c. to 7c.
Magnetite, calcined, per ton	25 to 35
Manganese ore, less than 0.75% Fe; less than 6% SiO ₂ , per ton	25 to 30
Mica, according to size, cleanness, and cleavage, per pound	1 to 8
Molybdenite, not less than 85%, free of copper, per % MoS ₂	8 to 12
Nohre, according to strength, crude, per ton	8 to 15
Sulphur, 99.5% pure, only trace of As and Se, per ton	15 to 18
Talc, lump, white, per ton	7.50 to 10
Tin ore, not less than 60% Sn, per % Sn	5
Tungsten ore, not less than 65% WO ₃ , per % WO ₃	2.75 to 3.00

T. A. RICKARD. . . . Editor

IF in these times of depression we have escaped a financial collapse it is due largely to the Federal Reserve Bank, which has given our national monetary system a stability such as it did not possess before. We believe firmly that the directors of the Federal Reserve Board have exercised their highly responsible functions with skill and fairness, therefore we have no sympathy whatever with the attacks now being made upon them in Congress.

GOODWILL between the two English-speaking nations of North America is proved by the unfortified boundary of 3500 miles that divides them so amicably. Another evidence of friendliness is the decision of British Columbia to establish the rule of "turn to the right" for vehicular traffic. This change will come into effect on January 1 next. The confusion due to having a "to the left" rule on the northern side of the boundary and "to the right" on the southern has been the cause of many inadvertent collisions; and the illicit trade in spirituous liquors, since the 18th Amendment went into effect, is said to have supplied another cause of accidents on the road. Safety first!

AGRICULTURE and mining are said to be the two basic industries. Apparently the older one receives most sympathy from Congress, at the expense of the tax-payers. A bill has been introduced to provide a billion dollars for the purchase of farm products. This is class legislation with a vengeance. Exports of farm products have been on an enormous scale during the last year. Up to May of this year 334 million bushels of wheat and 56 million bushels of corn had been exported, as against 198 million bushels of wheat and 14 million bushels of corn in the preceding fiscal year. A bloc, or organized group in Congress is behind this pernicious legislation, for which there is no valid excuse at this time.

FOREIGN mining companies operating in Spain will be hard hit by the proposed new taxation law, which, if given the royal assent, will lead to the withdrawal of capital and the migration of foreign technicians and business men. Spain, as a neutral, profited greatly from the War; the bank-rate was fixed at 4%, with the result that money went abroad, to be invested at higher interest. Since the Armistice, much of the accumulated wealth has

been spent on luxuries, and not in anticipation of the slump that follows the boom as inevitably as the night follows the day. The present drastic measure against foreign enterprise will hurt Spain no less than those who have invested their money and their abilities in expanding her industries.

THE official organ of the Union of German Metal Workers, 'Metallarbeiter', publishes the result of an investigation on the question of the increases in wages and the cost of living in Germany since 1914. In all about 2,300,000 workers were considered, and it was found that 63% are now receiving wages that indicate a rise of 800% over those of 1914; 36%, from 500 to 800%; and the remainder, less than 500%. As the cost of living has advanced about 1550% during the period under consideration, it is obvious that conditions in Germany are such that a great deal of credit must be given to that industrious country for having accepted the maxim that work is the best cure for many ills, individual and national. Germany is showing the world how it is possible to weather an economic crisis.

TEMPERAMENT and environment are factors that must be taken into consideration in deciding the length of the working day. The Association of Technical Workers in Germany recently decided that the retention of the eight-hour day in that country is an economic impossibility; it is claimed that the loss of 17 billion marks by the railroads during 1920 was due to the inefficiency that followed the introduction, immediately after the Armistice, of shorter working-hours. It is claimed that a return to the twelve-hour working day is imperative; with the extra four hours of leisure the German worker falls a prey to habits of dissipation, which unfit him for serious effort. This will astonish the members of labor-unions in the United States; to them it will seem a reversion to obsolete and archaic ways of thinking. The suggestion that rest from labor must lead to dissipation is archaic.

PROVIDED all the delegates come to the proposed disarmament conference at Washington with a realization of the stupidity and futility of war, then much initial progress will have been made toward a reduction of the economic waste that is crippling the world, and crippling it to no ultimate good purpose, mental, moral, or

physical. There must be no quibblings and no half-measures. Complete and universal disarmament is the ideal. The great powers can inculcate the truth by example; they can insist, by moral pressure, on its recognition. If there be still any nations that wish to resort to an archaic and barbarous method of settling a dispute, then the present is the best time to convince them of their mistake. In the proposed disarmament conference lies the hope of a disillusioned world.

THE latest bulletin issued by the American Mining Congress draws attention to the mention, in a U. S. Geological Survey report, of the closing of the North Star and Empire mines at Grass Valley, and asserts that "their closing emphasizes the contention that the cost of mining is not declining". This is a blunder of statement and of inference. The two mines mentioned have resumed operations, as noted in our issue of July 30. Moreover, the closing of these mines was due not to the persistence of high costs but to a disagreement between the managements and the men in regard to the extent to which wages should be lowered in conformity with the decline in the cost of living. The Congress bulletin proceeds to say: "It is expected other mines will close unless Congressional relief is afforded". Nothing of the kind is expected in California. We are expecting a re-opening of idle mines, and we have good reason to expect it, because the decline in the cost of supplies and in the rate of wages has improved conditions considerably.

DURING the first half of the current year the production of gold in the Transvaal declined to 678,490 ounces, as compared with 715,957 in the corresponding period of 1920. However, the enhanced value of the gold as measured in the paper currency of Great Britain raised the monetary yield to £3,646,883, as against £2,883,582 for the first half of last year. The so-called premium is greatly helping British gold-mining companies all over the world, for the reason that they do business in the paper pound, not in gold sovereigns. For example, Mr. John H. Cordner-James, speaking as chairman at a recent meeting of the Oroya Links company, owning a mine in Western Australia, stated that the company's operations would have been conducted at a considerable loss during the last fiscal year if the premium received on the gold had not come to their rescue. "It's an ill wind that blows nobody good"; but it is obvious that the depreciation of the pound sterling in Great Britain does not begin to compensate for the relatively small economic gain accruing from a premium on the metal produced from the gold mines exploited under the British flag. Meanwhile it helps our friend the miner, and we are glad of that.

A DENVER newspaper, namely, the 'Rocky Mountain News', displays lamentable ignorance when writing on the gold problem. In an editorial article it is asserted that "American bankers are paying premiums on foreign gold and loading up their reserves with it. Ameri-

can gold production is away down so that it counts for little in the total, whereas foreign gold production is being maintained from the American premiums paid". This is nonsense. American bankers can buy gold at the Mint for \$20.67 per ounce, as of old; they are paying no premium to anybody, because the American dollar will buy as much gold as before; the dollar is at par. On the other hand, the pound, franc, lira, and mark are each and all of them at a discount, which discount places gold at a premium in England, France, Italy, and Germany, but that premium does not exist in relation to the U. S. dollar, because the dollar has not depreciated in terms of gold. The producers of gold in foreign countries are obtaining no advantage from an "American premium", which is the figment of a disordered imagination and an ill-informed editorial mind. Those who produce gold in foreign countries, such as South Africa, owe their advantage to the discount on the pound sterling, which is worth as much less in gold as it is in U. S. dollars. That is all.

NEW ways of turning to account the benefits of co-operation are appearing continually. An instance is the project of Mineral county, in Nevada, for constructing and owning an electric-distribution system and for conducting a retail business in electric power that it will buy at wholesale rates from the Nevada California Power Company. The company formerly maintained a line of transmission from its hydro-electric plant at Lundy, in California, to Hawthorne, in Nevada, and thence to Fairview and Wonder. When the Nevada Hills and Nevada Wonder mines were at length exhausted there was no important market for power in these districts, and the line connecting the mines with Hawthorne was torn down. The company later made application for permission to remove the remainder of the line, whereupon the citizens of Mineral county protested that this would not only leave their towns literally in the dark but would seriously interfere with the development of the many small mines wherein lies the chief hope of the county's future prosperity. At this juncture someone suggested that the county bond itself to finance the construction of a power-line and then sell electric energy to the mine operators and others who desired to purchase. It was pointed out that the county had authority to issue bonds for the construction of roads; that roads were of little value to those living in the county unless the mineral resources were exploited; and that the most effectual way to promote mining was to supply electric power to the operators of small mines. A special bill providing for a bond-issue of \$150,000 for the purpose of building the line was endorsed by 90% of the property owners in the county, including the Southern Pacific railroad company, which incidentally pays more than half of the taxes, and was enacted by the legislature without opposition. The Supreme Court of Nevada passed favorably on the validity of the Act, and the bonds were issued. Sundry investment brokers offered to underwrite the issue at a substantial discount, but Mineral county wanted 100 cents

on the dollar. Here was another chance for co-operation. The Industrial Commission of Nevada gets 90% of its funds from the mining industry; the stimulation of mining will benefit the Commission; the financing of Mineral county's project will stimulate mining in Nevada. Accordingly, the Commission decided to invest \$75,000 in power-line bonds at par. This was a good start, and since then every bond has been sold at its full face value. The material has been purchased, and within a year a trunk-line so located as to bring power within six miles of all the promising districts in the county will be completed. The most important of these are the Simon and Candelaria districts, but Lucky Boy, Hawthorne, Luning, Rand, and Mina are centres of active prospecting and development; they are expected to flourish when electric power is available.

SEVERAL interesting contributions appear in our 'Discussion' department this week. To Mr. Bain's letter we make special reference elsewhere. Mr. Chauncey L. Berrien is the General Superintendent of Mines for the Anaconda Copper Mining Company, and when he writes about mine ventilation one can feel assured that he knows whereof he speaks. Mr. Berrien quotes at length from a Bureau of Mines report, to correct an impression that might have arisen as the result of an abbreviated reference in an editorial of ours to atmospheric conditions in the mines of Butte; he is inclined to question, as we did in discussing the matter in the first instance, the conclusion as to a rise of body temperature under such conditions. The Anaconda company has earned a reputation for initiative and interest in mining hygiene; its policy has always been to spare no expense in an effort to create healthful conditions underground. Mr. G. L. Holmes writes on the subject of another report issued by the U. S. Bureau of Mines station in Alaska. Our friend Mr. Alfred James, a recognized specialist in cyanidation, throws additional light on the subject of regeneration of cyanide after precipitation of the gold in solution. Mr. E. M. West writes from Tonopah to throw a brick at a grinning wild-cat incubated in his own district. From far-away Batavia, in Java, we receive a note from Mr. J. Egerton Wood on a disputatious subject, the value of gold. It will be noted that he found a gold sovereign worth 18 francs, whereas a paper pound was worth only 10½ francs, so that the premium on the gold was over 47%. Mr. R. B. Elder, who writes on the measurement of surface-tension, is Assistant Professor of Metallurgy in the School of Mines of the University of Idaho. His letter is timely, because on the next page we print an important article on the same subject by Mr. A. W. Fahrenwald, who is Ore-Dressing Engineer in the Field Office of the U. S. Bureau of Mines, at Moscow, Idaho, and is working in co-operation with the Idaho Bureau of Mines and Geology at the University of Idaho. Mr. Fahrenwald's method of measuring surface-tension ought to prove of great service in elucidating many of the obscure problems of the flotation process, with particular reference to adsorption phenomena.

Consolidation of Mines

Combination, followed by unification of control and management, often affords the best solution of an industrial problem, as we pointed out recently when commenting on Mr. Henry Ford's offer to lease the Muske Shoals plant and to operate it in conjunction with a new automobile factory. It is not always, however, that the more prosperous partner is willing to saddle his enterprise with the incubus of a venture of questionable outcome. Recently, the South African government appointed a committee of engineers to consider ways and means to avoid the closure of the East Rand Proprietary company's mines, on the Witwatersrand. The suggestions made by the committee included one that was favored in the majority report, to the effect that arrangements should be made between the East Rand and the Cinderella Consolidated companies, which are neighbors, to operate the two properties as one concern. This suggestion has not been met with enthusiasm by the Cinderella Consolidated officials; they are anxious to give the East Rand company every assistance in helping to surmount the difficulty, but they state that, from their own point of view, it would be more satisfactory to wait for the resumption of operations, and until such time as the Cinderella Consolidated is able to arrange its own finances, so that the mine may operate as a separate entity. With this end in view, optimism is expressed concerning the future prospects of the company as a profitable producer, provided it remain independent. On the other hand, the Cinderella company cannot view with complacency the prospect of the calamity that would inevitably result locally from the closure of the East Rand Proprietary mines, and has expressed a willingness to consider any reasonable proposal with regard to an amalgamation.

One notes the somewhat arbitrary advice in the majority report of the committee to the effect that the consolidation, presumably in the interests of South Africa and of the industry, should be carried out. Is it against common sense to suggest that a government is justified, morally or constitutionally, in preventing the decay of an industry by insisting on a consolidation of the prosperous with the needy? Ore ceases to be 'ore' when it cannot be extracted and treated at a profit; but if a mine that contains such material be situated next to one that possesses ore of such a grade that its prosperity for many years is assured, then the waste on the other side of the boundary-line assumes the prospective character of 'ore'. This being so, is it unreasonable for a government to conserve its mineral resources by insisting that all ore that can be treated at a profit shall be so treated, even if this be possible only by a consolidation between two or more companies? The suggestion opens interesting possibilities, for it is certain that many deposits would assume a vastly greater economic importance if such an average could be made. The question draws attention to the advantages of large-scale operation, unified control, and cheap methods of beneficiation.

Professional Advice From the U. S. Bureau of Mines

We take pleasure in publishing a letter from Mr. H. Foster Bain, the Director of the U. S. Bureau of Mines, with reference to an editorial in our issue of June 11 on the work being done at the Fairbanks station. We agree with Mr. Bain that the special conditions in Alaska justify some widening of the scope permissible to the engineers of the Bureau, and that under such conditions they may properly give detailed advice without trespassing on the field of the consulting engineer; in fact, our mention of this phase of the work was merely incidental to our criticism of the specific report regarding the treatment of tailing after amalgamation. As is natural, Mr. Bain defends the metallurgist whose work we criticized, and he does it most disarmingly. Nevertheless, in spite of the explanation offered, we venture to reiterate our conviction that the conclusions and recommendations in the original report were based on unsound metallurgical and economic principles. However, nothing can be gained by further debate on this matter. We are quite content to give space to Mr. Bain's friendly demurrer.

It is necessary, nevertheless, to point out that the technical man must base his judgment of the work of the Bureau on the reports as published, not on miscellaneous related facts that may be known only to the writer of such papers; on what the writer says (for instance, about the feasibility of cyaniding sulphide concentrates), not on what he may happen to know; and on what the writer advises to be done, rather than on what he may have in his mind to do after the plant is in operation. Mr. Bain manifests his appreciation of the shortcomings of this particular report in these respects at least. Even if we should concede that the general recommendations are based on sound metallurgical theory and practice, the report as it stands could be, it seems to us, of little value to the operators in the Fairbanks district; they would require so much supplementary advice that complete instructions might better be sent in the form of a letter. To the engineer who is not directly concerned with the Alaskan operations the report is either misleading if he be inexperienced, or ridiculous if he be one who has specialized to an extent that permits him to see its faults. The only possible function of the report might be to add one publication to the total number that is expected to impress the politicians, who hold the purse-strings, with the importance of the work of the Bureau. We hasten to disavow any inference that such could have been the purpose of publishing the report in question. Mr. Bain asks for constructive advice, and he is entitled to it, for his administration of the Bureau calls for the friendly support of the mining profession. We venture, therefore, to suggest that if the Bureau is to maintain its excellent reputation for honest technical research it must give more attention to the proper preparation of the reports that are distributed and published under the name of its engineers. A single unfortunate

publication will spoil the good effect of half a dozen valuable ones. Possibly we were brusque in our criticism of this particular report; if so, the curtness was due to a desire to be emphatic. The end in view was to forestall a repetition of a mistake that is injurious to the reputation of the U. S. Bureau of Mines.

Motor Traffic and Road Construction

Slogans are often lacking in common sense and logic. 'Build the roads to carry loads' is one that should be analyzed from the economic point of view. According to Mr. J. N. Mackall, the chairman of the Maryland State Roads Commission, the availability of money does not mean the construction of roads. The building of a nation's highways is a physical problem rather than a financial one; and the speed of building is limited to the materials and the mechanical equipment that is available and can be made available for the purpose. The makers of railroads were never confronted with the task that is now before the constructors of highways; the former could control the traffic over their lines. Although weight and speed have advanced enormously during recent years, these increases have never been sanctioned until the permanent way, the alignment, and the grade had been modified to meet the altered conditions. The highway engineer, on the other hand, is confronted today with the task of designing roads over which he has no control. The slogan should be, 'Limit the load to one that the road can carry'. If the user of the road, or the one who is interested in road construction, considered the economics of the subject, he would lose his enthusiasm and interest in roads for heavy traffic. Instead, he would favor the construction of roads to be built to withstand the wear and tear of trucks of moderate size, and the maintenance of those highways that are able to carry such traffic. This contention is supported by an example that serves to emphasize the need for a consideration of the economics of road construction. A census was taken of the traffic on the Maryland section of the road from Philadelphia to Washington, through Baltimore, during 1918, when long sections were destroyed by motor-trucks. In this census the trucks were classified according to size. It was demonstrated that, if all loads that were carried on units of five tons or more had been carried on units of three tons, the excess cost to the operators would have been \$15,000; whereas the cost of repairing the damage, a large portion of which was caused by the heavy loads, was \$600,000. An enormous economic waste is indicated; the figures serve to emphasize the futility of attempting to build and maintain a highway system under such conditions. There are today many more miles of road in satisfactory service than can be constructed during the next twenty years. Are these to be worn out in a few years by the traffic of a few exceptionally heavy trucks; or is transportation to be limited to vehicles of such a weight that the roads can be maintained in normal condition without inordinate expense for repairs or for re-building?

Charcoal and Wood-Oil Manufacture

The distillation of various oils from wood, and the production of charcoal and other by-products, are interesting features of the activities of the St. John Del Rey Mining Company, at Morro Velho, in Brazil. According to the annual report, the distillation plant there, of American manufacture, has a capacity of 200 tons of charcoal per month. The production for the past year was more than sufficient to meet local requirements, the surplus being sold. The supply is never equal to the demand; prices obtained are satisfactory. Another important by-product is calcium acetate, of which 181 tons was sold during the year. Gasoline is exceedingly expensive in Brazil, so the production of wood spirit, for use as a substitute, is of economic significance. During the year 71,000 litres was distilled, and 36,000 litres was sold. Tests with tractors showed that the spirit-fuel gives about two-thirds the duty of the same volume of gasoline, and improved results are anticipated in the future. No detrimental effects have been observed, by the substitution of wood spirit, on the cylinders and valves of internal-combustion engines; such working parts are reported to be in perfect condition after lengthly tests.

Wood-tar is another important by-product at Morro Velho. During the year an attempt was made to adopt it as a fuel in the refinery, as a substitute for charcoal, and with entirely satisfactory results. Fourteen tons of such material per month is now used for melting the gold; advantages are obvious, and economies are claimed. The brass-melting furnaces in the repair-shops are also being converted; and further uses for the local tar are being discovered. The engineering staff of the Oeste de Minas railway carried out successful experiments, in which tar from the company's distillation plant was used as a fuel. The light oils and pitch produced during the process of refining the crude tar are consumed in other operations. The insulating material used in the construction of the cooling-plant was made from cork grown in the neighborhood and from pitch obtained from the distillation plant; the efficiency of the covering leaves nothing to be desired.

The transport, by pack animals, of wood from the forest is expensive, difficult, and unsatisfactory. Various schemes have been considered to replace or to supplement the present freighting system by a less costly method of transport. Wire-rope tramways apparently are impracticable. Roads for light lorries driven by wood-alcohol have been suggested. It is realized that, if Brazil is to move with the times, some attempt must be made to replace the present primitive methods of transport, so as to avoid a criminal waste of time and money. Unfortunately, however, the country is confronted with a financial crisis; the St. John Del Rey company has no market at present for its calcium acetate. For this and for other reasons the general manager, Mr. George Chalmers, expects that it will be necessary to reduce the activity and the output of the distillation plant. Whatever the effect of the economic crisis may be on this phase of the company's operations, it is evident that the officials have

made a praiseworthy effort to meet abnormal conditions, and that a technical success has resulted from their enterprise. Charcoal is used extensively as a fuel in mining districts; the distillation of crude oil from wood is apparently so practicable that other companies, similarly situated, are likely to utilize local raw material for the production of fuel for motors, as well as other valuable by-products.

Tube-Mill Pebbles and Colloids

The investigation of technical advance in other industries would add to our knowledge much that is essential. At present we obtain such information in a haphazard way. A certain amount of overlapping in research is inevitable, but it is doubtful whether any appreciable advantage is taken of investigations on subjects in which we are not directly interested—information that, if sifted and classified in a manner that would make the essential features clear and the applicability obvious, would be of immense value. As an example of this we refer to the use of artificial pebbles in the crushing of ore. The mining industry, as has been its wont, muddled along for many years without scientific guidance as to the character and the properties of the rock that should be used as a grinding medium in tube-mills. Flint pebbles were imported from Europe at enormous expense to serve this purpose; we could afford the first cost, the freight, and the other charges. Many of these stones had been subjected to alternating periods of cold and heat for centuries; a large number of them cracked and chipped with the first revolutions of the mill. Nevertheless it was maintained that the imported article was not only of superior quality, but that its use was an essential to successful grinding. In a few instances, however, the cost of haulage to a reduction plant in an isolated district was so great that the use of a cheaper substitute was considered. Rough mine-rock was tried, but in the majority of cases the results were unsatisfactory; it chipped and broke; the efficiency of crushing was seriously reduced by the accumulation of gravel and sand in the tube-mill. Power was wasted; although the grinding medium was ore, this advantage was more than countered by the reduction in the output of the re-grinding plant. An effort was then made to find a barren-rock substitute of approximately the same character as the imported pebble. It was ascertained that such material existed almost everywhere; it could be mined or quarried, and shaped to a size that was consistent with the work it would be called upon to perform in the mill. A preliminary tumbling treatment in a cylinder resulted in the production of a pebble of the same appearance as the European water-worn flint. Sceptics said, "It is softer than the imported article", which was true; but, in determining the requirements of a first-class tube-mill pebble, other factors must be taken into consideration. The hardness of the material used for grinding is of no significance if the stone breaks easily under impact; and this is what happened to a large proportion of the imported pebbles. In one instance, two piles of pebbles were made; one of these

was of imported flints; the other, of shaped stones of felsite, selected according to a diameter (and, accordingly, weight) that suited the requirements exactly. The tester, standing about six feet from the pile, would throw, in succession, a number of European pebbles among others of the very same character, with the result that many were unable to withstand the impact. The imported pebbles were hard, but they were also brittle; the chipplings produced in the mill during normal operation required a considerable expenditure of power before they could be reduced to fine sand or slime. The same test carried out with the felsite stone showed no fracturing and no chipping, but some abrasion. The substitute could be manufactured for much less than the European pebble could be purchased and hauled to its destination; comparative tests in the tube-mill showed it to be more efficient as a grinder because of (1) uniformity of size; (2) greater weight per unit volume; (3) absence of chipping and fracture; and (4) comparative roughness of surface, thus permitting a better grip during the grinding.

At this stage it was realized that a scientific appreciation of the factors of hardness and toughness of pebble and rock would be of value, and an examination was made of current technical literature. This proved a tedious task, but it was fruitful of result, for it was found that a large amount of experimental work had been done, on the testing of rock for road-building purposes, at the laboratories of the Office of Public Roads and Rural Engineering. It was then realized that the essential features of road-metal, namely, hardness and toughness, are also the essential features of tube-mill pebbles. The selection of a proper rock for ore-crushing was therefore practicable at the minimum of trouble and at a negligible cost, for the laboratories at Washington are equipped with apparatus by which accurate and scientific tests can be made on any type of rock, and its suitability or unsuitability as a grinding medium can thus be determined. The testing of rock has been carried out on so extensive a scale that the bulletins of the Office contain details as to deposits of suitable stone in almost every locality, and their availability for the manufacture of an efficient and inexpensive substitute for imported pebbles.

At the Colorado meeting of the Institute in 1918 a paper, by Mr. Luther W. Lennox, was discussed. In this the author showed that a fair idea of the comparative friability of ores could be obtained by the use of a small tube-mill, loaded with steel balls. The sample, it was explained, was crushed to a coarse mesh, graded and weighed, then introduced into the testing machine, together with a definite amount of water. After a pre-determined period of grinding, the ore was removed and an estimate was made, by screening and weighing, of the amount of the sample that had been ground to pass a screen of a certain mesh. From this a value was obtained representing the friability of the ore. The model tube-mill was somewhat similar to the apparatus known among road-building engineers as the Deval abrasion

machine, used to determine the French coefficient of wear, except that no balls are used in the latter case, and the axis of the mill is at an angle with the horizontal, with the result that a greater abrasive effect is produced. Thus it happened that an engineer in a private capacity developed a scheme for estimating the hardness of rock, a subject that had already received considerable attention, and on which large sums of money had been spent, in another industry. This will indicate the need for the systematic recognition of contemporary research. Mining and metallurgical engineers can turn to no comprehensive index and résumé of current technical literature, compiled by one who appreciates the value of a pertinent scientific fact, irrespective of its source; the economic waste that results from the unnecessary overlapping of research appears inevitable until such a résumé is available.

One man's meat is often another man's poison. Colloids of clay and of other earthy substances are the bane of many a chemico-metallurgical operation, but they are the delight of the maker of fine porcelain, and are of value to the agriculturist. A method of determining quantitatively the amount of colloid in a slime would have ensured the avoidance of many a fiasco in filtration; a scientific analysis of the physical characteristics of an ore is often as important as a chemical or a metallurgical analysis. The hardness and the toughness of a rock can be determined, as we have shown, by means of the apparatus described in the reports of the Office of Public Roads and Rural Engineering, and the friability by Mr. Lennox's method; but a determination should also be made, among others, of the colloid content; and in this connection we are glad to borrow some suggestions from the Bureau of Soils of the U. S. Department of Agriculture. Recently a paper, by Messrs. C. J. Moore, W. H. Fry, and H. E. Middleton, on 'Methods for Determining the Amount of Colloidal Matter in Soils', has been published; the experiments that have been and are being made should arouse the interest of the mining and metallurgical fraternity. From this paper it is learnt that a method for isolating the true colloid was perfected. An 'ultra-clay' was produced that was unfilterable; it proved to be a much stronger binding agent than portland cement. Two methods were devised to determine, quantitatively, the amount of colloid present in the soil. In the first case the results were based on the power of the dry colloid to adsorb a gas (ammonia); in the second case, to the power of a colloid in the form of an aqueous solution to adsorb the dye from a true solution. The experiments are being continued; the results should be followed by those who are interested in the physical characteristics of rocks, decomposed or disintegrated, all of which, when sufficient metal is present, may be designated 'ore'. We draw attention to the work of the Bureau of Soils in an attempt to emphasize the importance, to the mining and metallurgical fraternity, of the research that is being done, particularly with regard to the estimation of the physical characteristics of rocks and soils, in our Government departments.

DISCUSSION

Professional Advice From the Bureau of Mines

The Editor:

Sir—In your issue of June 11 you have been good enough to discuss one of the very real problems faced in the administration of the Bureau, although, unfortunately, you have done so on the basis of a single example, and, as I think, without quite your usual breadth of view and insight. In your editorial there are two material criticisms, first, as to the policy of the Bureau ever giving advice to individual producers which might be obtained from a practising engineer, and, second, as to the value of the particular advice given. With your permission I will discuss these separately.

There can be no real difference of opinion among engineers inside or outside of the Government service as to the soundness of the rule that those working for the Government should not trespass upon the proper field of those who earn their living by the application of their technical skill in general practice. Indeed, so far as the Bureau of Mines is concerned, this is not only a matter of fundamental policy, but is, by strong implication, prohibited by the organic law. It is, however, a principle of interpretation that no law requires an executive officer to desert his common sense, and the brilliant editor of the 'Press' has himself accepted the rule that all rules are subject to exceptions, "except that a man must be present while being shaved".

The work of the Bureau in Alaska is considered to fall among the exceptions, and this conclusion was reached deliberately and after mature consideration of the particular conditions to be met there. The experiment station was established at Fairbanks to pioneer and with full knowledge that the character of its work would necessarily differ from that of those in the States. Approximately 98% of the land in Alaska is still owned by the Government. The conditions faced by prospectors and miners in the Far North are difficult to an unusual degree and they deserve and should have every help which the Government can give. Under the leasing system, which applies to the coal and petroleum lands, the Government is a continuing partner in each enterprise and directly interested in its success. In securing development of the other mineral lands of the Territory the Government has the interest in making a land market that any other large land-owner would have. It has in both cases the larger and more important interest in public security and welfare which will result from making in our northern territory homes for people and

building up strong, well-founded, and economically independent communities. For these reasons the Bureau has felt warranted in going further in giving direct aid to miners and prospectors than in its regular work in the States. The situation is not the same as where much if not all of the land has passed into private ownership, where industries are established and running, where standard practice has been developed and is well known, and where private facilities for investigative studies and tests are abundant. There are now no facilities available for making tests other than those of the Bureau. It hardly seems justifiable under these conditions to raise the cry of competition with private enterprise.

The tests made at Fairbanks, of which one formed the basis of your criticism, were intended to suggest to operators in interior Alaska the possibility of additional gold-recovery from their ores after amalgamation. The tests were made on an amalgamation tailing obtained from one among several similar properties in the Fairbanks district. The mines are all small, the ore occurring in veins usually less than a foot in width. Development has not been carried on to demonstrate a large tonnage and the owners are in no case prepared to make large expenditures. There are no practising metallurgists in interior Alaska, and none of the properties in the Fairbanks district are yet on a sufficiently large operating basis to warrant the expense of individual investigations. That these tests were in the nature of a preliminary investigation is suggested in the concluding paragraph of the report, which reads: "Whether concentration and cyanidation, or flotation, is to be adopted, should be determined by tests of a representative amalgamation tailing derived at least in part from sulphide ores." I believe that with this larger knowledge of the situation you will agree that this was a proper activity on the part of the Bureau and did not in fact constitute a case of trespass.

With regard to your criticism of the tests themselves, I am persuaded that the real fault is more with the form of statement, or perhaps the making of any public statement, than with the work itself. Only a part of the work done was described. It had already been demonstrated in a number of cases that in the amalgamation of the Fairbanks ores, no economic improvement could be expected.

A few runs only were made in a custom-mill on the ore from this particular mine, and the accumulated tailing was not sufficient to warrant the erection of a plant for mixed sand and slime. The attempt to leach mixed sand and slime for current production, it was

believed, would simply result in a tank-charge impervious to solutions. Cyanide tests were made on the different products from table concentration to determine the extractions on each. The results obtained by such tests determine whether it is advisable to cyanide the concentrate with the sand, or to remove the concentrate for separate treatment, or for shipment to a smelter. The ratio of solution to ore in the tests was two to one. The mention of this in the report was not deemed necessary, as the important point (the cyanide and lime consumption in pounds per ton of ore) is given for each test. This consumption was not excessive nor was it higher (except in the case of slime treatment) for the longer treatment.

As to the bottle tests, there is room for difference of opinion. Much depends on the exact method followed and the amount of reliance placed upon the results. These particular tests were made by hand agitation which simply means occasional agitation during the day and none at night. Moreover, the removal of all the solution by repeated washing was not attempted; only enough water for washing being used to bring the solution back to the original volume. Such a method does not yield over-high results, the chief danger from bottle tests. As a matter of fact, Mr. Gross, who did the work, has made similar tests in a number of plants in actual operation and checked results by extraction over periods of several months and found the bottle results slightly below mill-recovery and the cyanide and lime consumption above. For preliminary work on small properties, bottle tests are far from being useless and they should not mislead an experienced operator.

The statement that high extraction cannot be expected from sulphide concentrate was not intended as a general dictum but referred to concentrate from the particular ore tested and was based upon results obtained from testing this and similar ores in the Fairbanks district. Neither was it intended to convey the idea that this concentrate could not be so treated as to give a good extraction, but that under conditions existing in the quartz mines of the Fairbanks district a high extraction from a sulphide concentrate is of improbable economic value. The fault here is in rhetoric, rather than technology, and is cheerfully and fully acknowledged. Per contra the implication of the critic that Mr. Gross was entirely ignorant or regardless of the literature of the subject is amusing in view of his experience in the cyanidation of sulphides which dates back to the elaborate studies of Draper and Gross at Central City in 1910, and has extended through a wide experience as an operator in Mexico and the United States.

In the outline of the mill suggested, the table would remove a concentrate if necessary for shipment and would discard the slime. While it might appear that a high loss is occasioned by not treating the slime, anyone familiar with conditions in interior Alaska would hesitate to recommend its treatment at present. A table of the Wilfley type can make a sand product sufficiently free from slime to allow wet loading in a tank and to

ensure satisfactory leaching; in other words, the table could not only be used as a concentrator if required, but would also take the place of a drag-classifier. It was not suggested that the concentrate from the table should be cyanided separately. In case a high-grade concentrate was not obtainable, the entire table product, except slime, should go to sand-leaching tanks. The table, in this case, should be used simply for the removal of the slime, although at any moment ready to remove a concentrate if desirable.

There is no reason why an excessive amount of water should be sent to the tanks with the sand-pulp. If the sand-pulp be not contaminated with an undue amount of slime, a leachable charge will be obtained.

As it was not intended to use an alkaline mill-water, the return of the water to the mill need be considered only in case of shortage. The alkalinity for the protection of the cyanide would be obtained after the removal of the water by placing the required amount of lime on the top of the charge to be taken up by the solution. This method was found to be satisfactory in a mill operating under the same conditions.

It is true that all solutions from leaching-vats should not pass through the zinc-boxes, but in a small plant where only one vat is being leached at a time, simplicity of construction and the avoidance of having zinc-boxes standing idle (which does not improve their efficiency) are perhaps sufficient reasons for passing all solutions through the boxes. While it is admitted that it might be better, even in such a small unit as the one proposed, to carry two solutions in the plant, it is a minor point of treatment easily initiated in the mill if found advisable.

The flotation tests on the slime were preliminary tests made for the purpose of determining whether an operator would be justified in considering flotation in the treatment of his ore. The tests on this particular ore did not make a shipping-grade concentrate, but an extraction of 62.7% of the gold can certainly be considered as sufficiently encouraging for further tests, which are stated in the report to be necessary.

With this explanation I think it will be agreed that the faults seen by the critic are due rather to failure in presentation than to the scope and character of the tests made. The latter were designed to meet a particular condition and are believed to have done so. The men most concerned, living in the community and participating in the work, lost nothing by the over-brevity of the report, a fault possibly due to over-earnest effort to meet the criticism of the 'Press' on the bulk of Government printing.

As I mentioned at the beginning, the matter is one phase of a large problem that must be met in the administration of the Bureau. Your New York contemporary has already referred to it and I should be glad to have further discussion and the advice and help of fellow-members of the profession in determining the correct lines of activity for the Bureau in bridging the gap between laboratory results and commercial practice. How is the difficult and expensive stage of semi-commercial

development of processes to be passed? Many problems are to be met here and the officers of the Bureau are by no means cocksure that the methods now followed are wholly sound. They have at least the merit of evolution and of having grown out of experience. The system of research fellowships, of temporary semi-commercial operations and co-operative agreements does produce results and does have points of merit, but no one can be more conscious than those in the Bureau that it is also open to criticism. Can any one point to a better way that is applicable under actual conditions? Your help is cordially requested and will be sincerely appreciated.

Now may I say just one word to recall the fact that it is constructive criticism that helps and that when in the judgment of a critic he must write in terms of destruction, a sympathetic tone is never out of place? Specifically it does not help to attract to or hold in the Bureau men of broad operating experience when their reports are referred to as "a joke". I submit with all fairness the past services of the Bureau warrant a keener effort to get at the missing facts in the case even where the fault in presentation rests with the Bureau.

Washington, D. C., July 15.

H. FOSTER BAIN.

Ventilation and Phthisis

The Editor:

Sir—In your issue of June 4, 1921, page 770, you called attention to a preliminary report upon 'Ventilation and Miners' Phthisis', and particularly to the fact that out of 1018 miners examined 432, or 42.4%, were found to be suffering from phthisis.

Owing to the fact that some might misconstrue this to mean that 42.4% of all miners in Butte are suffering from phthisis, or miner's consumption, I wish to call your attention to the statement on page 10 of the preliminary report quoted as follows:

"There men presented themselves for examination at the office of the Butte Anti-Tuberculosis Society after notice had been given verbally and by printed card that all miners who would come to the office at certain hours would be examined free of charge. No examination was made of all of the miners of the Butte district or all those of any particular mine. Of those examined, a large proportion knew or thought they were infected when they presented themselves. Of those examined 432, or 42.4%, showed definite signs of dust injury to the lungs. Practically all of these men were either still working or had quit within the previous two or three months."

You can readily realize from the quotation of the full paragraph that very few, if any, miners would submit to physical examination unless there was suspicion that they were affected by the disease, consequently a very high percentage of those examined would show symptoms. In fact, it is rather surprising that the percentage was not higher when it is realized that only 1018 submitted to examination out of a probable total of 20,000 miners employed in Butte at that time.

Calling further attention to the article in question, I

note that you quote from the Bureau of Mines Report as follows, "in most of the working places examined in Butte the temperature was well above 70° F., little or no movement of the air was perceptible, and the humidity approached saturation. Comparatively little work in such places causes body temperature quickly to mount from 98° F. (normal) to 103° or higher—that is, to fever temperatures".

We believe these results were obtained by noting the effects on Bureau of Mines observers rather than on the hardened miner. In justice to the mining companies in Butte, and particularly to the largest operator in Butte, I think your quotation of the report should have been extended to include the following:

"While the upper levels of the mines in this district were being opened, a considerable quantity of low-grade ore that was not of commercial grade then was left unmined. Because of the great reduction in mining costs during the last few years, the better price for copper, and, particularly, the lower cost of production, and the increased percentage of recovery, this ore is now of commercial value. Recovery of this ore has necessitated the reopening of many of the upper levels, and hence the operation of a large number of levels at the same time. For this reason, it is difficult to ventilate properly all of the working places in such mines; however, the mining companies are working as expeditiously as possible to extract this low-grade ore in order to eliminate as many levels as possible and to confine mining to fewer levels. The companies intend when this ore is extracted to seal off the worked-out levels with concrete so as to prevent the good fresh air from being vitiated.

"Almost all of the mines have one or more upcast shafts besides the operating shaft, which at nearly every mine is the downcast, and an effort is being made to have every operating shaft a downcast.

"Large, double-intake, reversible Sirocco fans, electrically driven, are installed at the collars of most of the upcast shafts. In some mines No. 11 Sirocco fans, also electrically driven, are used as boosters in the lower levels with satisfactory results, and in most mines small electrically driven fans with canvas pipe or tubing are installed in raises, drifts, and crosscuts to force the fresh air from the main air passages to the dead ends. *One company purchased at one order 325 of these small fans. This company has nearly completed plans, after working three or four years on them, that will double the volume of air circulating in its mines. Nearly all of its mines are ventilated independently of adjoining mines, and an effort is being made to provide independent ventilation for the others.*

"One working shaft is nearly all of solid concrete, a large number of other working shafts are coated with gunite, and a large number of upcast shafts are smoothly lined with concrete slabs, thus making the shafts fire-proof and at the same time reducing the frictional resistance for the air. The smooth surfacing of these shafts permits almost a doubling of the velocity of the upcast, and thus doubles the quantity of air that can be

exhausted per minute by the large suction fans at the collar. One mining company has planned and has authorized continuation of this work, so that when its plans are completed every one of its working shafts will be coated with gunite and every one of its upcast shafts will be smooth-lined with concrete slabs.

"The conditions at the deeper Butte mines are difficult and intricate, and the mining companies have for many years past spent much time, energy, and money in efforts to solve the problems involved. Much progress has been made, but much remains to be done. *The recommendations following are offered with full knowledge that many of them are already in effect at some mines, but with the hope that their adoption may become general.*"

I desire especially to remind you that the Anaconda Company had initiated the changes in ventilation and general operating conditions some time before the U. S. Bureau of Mines began its investigation, and is continuing such work as rapidly as possible. The recommendations suggested by the Bureau of Mines had been and still are the methods of common practice in mine ventilation and their adoption has become general, but cannot be carried out in a short period of time throughout twenty-five operating mines.

Butte, July 14.

Gold From Black Sand

The Editor:

Sir—As I have been away on business for some weeks I did not get my 'M. & S. P.' regularly and find, on returning here, that my screed which appeared in yours of May 14 has elicited a response from Mr. Gross. To set forth my reasons for my comment on the paper 'Recovery of Gold from Black Sand', which appeared in your issue of April 9, I will beg your indulgence again.

To quote from the original article: "most of the gold present was 'contaminated' with quartz, as the free particles of gold had been removed by amalgamation". We must remember that the gentleman is speaking of placer gold and that by free gold he evidently means gold which is absolutely free from any 'contamination' with quartz or other material, and not 'free gold' as known to the quartz miner.

In the letter of June 25, Mr. Gross states: "The purpose of the investigation was not simply to recover the gold contained in this black sand but to ascertain some method whereby the placer miner could, without too much expense, either in the way of labor or additional equipment, make a better saving on this material"

For the benefit of Mr. Gross I will state that I am familiar with conditions existing (or as they once existed) in the interior of Alaska, having made some extensive trips in that country as early as 1900 and later having owned some ground on O'Brien creek in the Forty-Mile country. I must also take issue with him on his statement that "black sand is a local term". This term is used all over the world in placer-mining circles to denote just what it calls for, "black sand", heavier than

the general mass of the placer material, which remains behind as a concentrate in the pan or sluice. In various districts we have sands of other colors which remain behind, the 'ruby sand' of Nome is an example, and such material should preferably, in a pseudo-scientific article describing tests made at a Government Experiment Station, be properly described or called by its proper name rather than by some misleading colloquialism.

The object of the test was "to ascertain some method whereby the miner could, without too much expense either for labor or additional equipment, make a better saving on this material". Then why resort to classification when classifiers are expensive, to Abbé mills which are also costly and are not in general use in placer-mining districts and are not carried in stock in remote regions by the general stores. Jigs were also used and a properly made jig is also an expensive (comparatively) piece of apparatus which the average placer miner knows neither how to construct nor how to use. Where, in a remote placer-mining region would one find a miner capable of determining that the "rising velocity in the classifier was exactly 54 ft. per minute"?

Mr. Gross would possibly be a bit more correct in his statement if he said that the average Alaskan does not regard 11c. per pound material as being of much value when in comparatively small quantities. A real placer miner takes more pride in his work than would permit of his being careless in cleaning 770 lb. of such material.

Let us examine the facts. The gold "was contaminated with quartz", by which I understand that a portion of it had not been freed from its original matrix of quartz. Can we remove it by classifying? No. There is only 770 lb. of the material, but grinding this amount in a hand-mortar or on a bucking-board would be arduous, and these appliances might not be handy in a placer camp. What more natural then than the two flat stones I mentioned. Nothing but grinding is going to release the gold from its matrix and two flat stones of suitable size can be found at or near almost any placer mine. If this amount of material is to be recovered at every clean-up, and clean-ups are to be at weekly intervals throughout the season, a small arrastra could be built by driving staves into the ground in a circle, lining the bottom with flat hard stones and a sweep provided with drag-stones so that the operator could walk around the arrastra and grind the material fine enough to release the gold. I have seen such arrastras built in remote regions by artisans who had few tools and small skill in the mechanic arts. They are effective and accomplish the desired result with a minimum of labor and expense.

Some years ago, while visiting one of the Alaskan placer camps, I witnessed a clean-up and was surprised at the somewhat careless way a certain group of 'miners' handled their clean-up work. It also happened that this was the first clean-up that their new cook, an elderly lady from the Snake River country in Idaho, had witnessed. She remonstrated with them and was told that there was "no fine gold here". She did not believe the statement and begged them to throw their tailing from

the clean-up into a pile for her. Later I saw her carrying some of it in water-buckets to her kitchen, where she dried it in small portions in a clean skillet and resorted to skillful 'blowing' on a sheet of tin, which she had burned in the fire to remove the tin coating. I saw her get quite a nice showing of fine color, and, in the fall of the year, I saw her in Skagway homeward bound and found that her efforts with the supposedly valueless material had netted her some \$15,000 for the season. She had been brought up in a placer-mining country by careful parents who were placer miners themselves.

With placer clean-ups, in the average ordinary sense, there is no use for classifiers, jigs, vanners, or what not. If some of the gold is still attached to quartz or other material, grinding alone will release it, and the quantity of material and its value per pound will determine how much expense for grinding and grinding equipment can be permitted. The small arrastra is the cheapest, most ancient and honorable, and probably as efficient as any of the small ball-mills or other fine-grinding apparatus. It can be run by man, mule, or water power and when the entire operation is finished and the camp about to be abandoned, the arrastra can be dismantled and the adjacent soil rocked or panned for the final recovery of almost all the values lost during its use.

I cannot imagine the use of what we commonly call a canvas-table for the saving of gold from such work, as canvas-tables are only suitable for very fine material, 'slimes' in fact, and such fine screening or classification cannot readily be accomplished at a remote placer mine. At any rate, the material should be ground finely before anything else is attempted, and, as it will be possible to amalgamate, in most cases, practically all the recoverable gold while such grinding is being done, why not start out by grinding fine and eliminate the rest of the treatment?

Cyanide Notes

The Editor:

Sir—The very interesting article by Algernon Del Mar, in your issue of June 11, emphasizes an apparent regeneration of cyanide after zinc-dust precipitation. He does not tell us what authorities were available in his library of "major size", but it would seem not to have contained the Transactions of the American and British institutions of mining engineers or of the Society of Chemical Industry or my book on 'Cyanide Practice' (1901), in which I collected my papers.

The subject has received more attention than Mr. Del Mar thinks. In the Transactions of the American Institute of Mining Engineers, Vol. XXVII, p. 283 (see also p. 124 of 'Cyanide Practice'), I point out that the apparent regeneration is apt to arise from the absence of a satisfactory test. "It is well known that the presence of alkali or alkaline carbonates, always present in used solutions, interferes with the silver nitrate test making the solution appear to be stronger in available

cyanide than is really the case. Chemists in charge of works should, therefore, be careful not to be misled by this test, or lowered extraction may result. The effect of caustic potash or soda on double cyanide of zinc and potassium is *not* to regenerate all the cyanide of potassium as shown by silver test; the test, as suggested by C. J. Ellis, being rendered unreliable by the silver throwing out the zinc from the double cyanide, and the zinc so displaced being dissolved by the KHO present, thus prolonging the titration."

That the double cyanide of zinc and potassium in the presence of caustic potash does not split up into simple cyanide plus oxide of zinc and potassium—compare point No. 1 in Mr. Del Mar's penultimate paragraph—was determined by a series of experiments involving the crystallizing out of the products which were analyzed (see p. 129, 'Cyanide Practice'). These experiments proved that the reaction is really $\text{K}_2\text{ZnO} + 4\text{KCy} + 2\text{H}_2\text{O} = \text{K}_2\text{ZnCy}_4 + 4\text{KHO}$ and not the reverse.

Perhaps the greatest argument against the so-called zinc-box regeneration is stated on p. 147 (same book)—the fact that cyanogen does not appear to accumulate in the sump solutions. Argall gave effective proof of this (p. 148).

Concerning Fakes

The Editor:

Sir—We who reside here have noted with considerable interest and silent applause your fearless criticism of George Graham Rice and others of his kind. We all know, if we are honest and candid with ourselves, the irreparable damage such fake-promoters do to the mining industry, particularly to the interests of the legitimate promoter and prospector. We who live here are naturally somewhat used to such concerns as you so justly condemn, but my thought dwells on a question that recurs to me whenever I think of crooked worthless promotions, and that question is how can such a proposition as the Cornucopia Divide Mining Co., the prize fake of the Divide district, an out-and-out wilcat in both properties and management, circulate its "engineer's" reports (these reports were prepared for the "Company" by a local assayer who signs himself M.E. Said M.E. received as a fee some 1000 shares of the stock to act as a 'come on' and assist in swindling his fellow-men). Their "President's" report and "annual" statement are fine, but why can such a concern circulate these fake reports with impunity? and furthermore why should they enjoy the privileges and benefits derived from operating under the sanction and permit of the Commissioner of Corporations of the State of California? The State of Nevada has suffered as no other Western State has suffered from the effects of just such corporations as the Broken Hill and Cornucopia, but this is the first instance I have noted where a permit was asked for

and received by a company of this type. It must have taken monumental nerve to put this across, but it 'worked'. A fake company masquerading as legitimate (especially if having secured a permit) is doubly dangerous to the public and no mercy ought to be shown in turning the spot-light of publicity on such concerns. The public is entitled to such protection as the 'Mining and Scientific Press' affords by publishing the facts.

The Value of Gold

The Editor:

Sir—In reading the letter of Mr. Robert B. Brinsmade in your issue of July 31, 1920, which has only now reached me, I am reminded that in this and many other letters and articles dealing with the increased cost of living, increasing wages, and so on, little or no consideration is paid to the problem of how it is to be done. Thus I see in one of your leaders in the same issue you state that \$3.34 per day for a miner is not enough. Before the War I take it that in England the daily pay of an average laborer, skilled and unskilled, would be about the value of two grammes of fine gold. This I was under the impression meant that the same amount of labor in one form or another (machinery and tools represent so much labor) was needed to produce two grammes of fine gold. The cost of producing gold must include the costs at the unprofitable gold mines as well as the profitable. I presume that the currency of both America and Europe is still on a gold basis; and if this is so, it is a mystery how a laborer is to receive more than the two grammes of gold per day unless he does more work. Even if all people were paid the same, Cabinet ministers, managers, and laborers, the equal division would not add much to the two grammes. If the gold standard is abandoned, there is no necessary limit to the value labor can demand for its work. But it is a waste of paper. Further, it is robbing all the poor people who had been saving for old age.

Temporarily I am living in a remote district in Sumatra, where there is little money, and nearly all the trade of the natives is done by barter. We who have to use money, have to pay more for local products such as rice, fruits, fowls, and eggs, because, as the sellers explain, they have to pay more for cloth, pots, and pans, and so on. This is quite understandable, and the people who live here and only work for themselves feel no change in conditions. It is not conceivable, however, that in any country one large part of the population, such as the colliers, shall continue indefinitely to be able to demand the equivalent of several days work from another for one day's work by them.

You refer to the bounty on gold. The other day I had to buy some sovereigns, and the Java Bank, which is the National bank for the Netherlands Indies, charged 18 francs each, whereas at the same time they only paid me 10.50 f. per pound for a draft from London!

However, as long as the world is run, as it is, selfishly,

and the highest business morality is to buy as cheaply as possible, and sell as dearly, whether it be soap, cloth, or manual labor, there does not seem much chance of solution outside the laws of evolution.

Batavia, October 9, 1920.

Measurement of Surface-Tension

The Editor:

Sir—The method of measuring surface-tension attributed to Dr. A. Ferguson and described in the short paragraph on page 124 of your issue of July 23 is known as Jaeger's method, and is one of the well-known methods of measuring this force. A description of the method and an analysis of the mathematics involved is given by Ferguson in the 'Philosophical Magazine', Vol. 28, July 1914, page 128. In the same magazine, Vol. 28, September 1914, page 403, is another article by Ferguson 'On the Surface-Tensions of Liquids in Contact with Different Gases', in which results are given as obtained by the use of this method. In 'Science Progress' of January 1915, Dr. Ferguson, under the caption 'Capillary Constants and their Measurements', gives a critical account of twenty methods for measuring surface-tension, in which Jaeger's method is included.

In practice, Jaeger's method consists in measuring the maximum pressure required to liberate a gas bubble from the end of a vertical capillary tube plunged beneath the surface of the liquid, or in contact with the liquid, the lower end of the capillary being on a line with the level portion of the liquid surface. At the laboratory of the University of Idaho School of Mines, Jaeger's method is used in conjunction with the method of weighing the tension in a bubble film. Surface-tensions have been studied extensively in connection with the investigation of flotation phenomena, and laboratory devices have been made which make the method of weighing the tension in a bubble film a rapid accurate laboratory method for measuring surface-tension. Articles describing the work and apparatus are soon to appear.

In case of pure liquids, results by these two methods are in very close agreement. When a contaminant which changes surface-tension is present in the liquid, results by Jaeger's method are always higher than those obtained by the other method, and this is true whether the contaminant lowers or raises the surface-tension of the solution. The tension of a freshly formed surface of a liquid containing a contaminant, as measured by the film method, is greater than that of an older surface similarly measured, and approaches the tension as measured by Jaeger's method.

In the case of the older surfaces, an approximate equilibrium is established between the surface and the solution; the factors tending to establish this equilibrium are time and agitation without aeration or the passing of bubbles through the solution.

Surface-Energy and Adsorption in Flotation

By A. W. Fahrenwald

INTRODUCTION. Theories of flotation have shown little development during recent months. One reason is that most of the possible physical and chemical explanations have been discussed, and nearly every theory advanced has left much wanting. Exact data and measurements have been difficult to collect, owing to the number of variables involved and the difficulties of designing experiments that could tell anything.

By making use of one of the fundamental laws of colloid chemistry it was possible to design a number of experiments from which I have been able to obtain some data on certain previously unanswered questions in flotation.

The purpose of the present paper is to discuss briefly an instrument developed for measuring surface-tension and the way in which it has been applied to the study of flotation. Further work is in progress, but the results so far obtained have proved of such interest that immediate publication of some of them seems justified. Certain reservations are made in the paper pending further experiments.

Flotation is a process involving the physics of surface-energy, including adsorption, and it appears that a study of these phenomena is indispensable to a solution of the problem.

The interfacial tension theory of flotation is now generally accepted. It was first suggested by O. C. Ralston,¹ who applied the inequalities of Reinders. These inequalities were further applied to explain flotation by Taggart and Beach,² by Taggart³, by Corliss and Perkins,⁴ and more recently by Frederiek G. Moses.⁵

In the present paper a preliminary quantitative study of certain surface-energy and adsorption phenomena has been made for the purpose of learning, if possible, exactly what takes place in a flotation pulp.

ADSORPTION. It is well known (1) that solids adsorb or hold closely to their surfaces certain gases, liquids, and molecules or even ions; (2) that liquids adsorb or hold closely to their surfaces gases, liquid globules, small solid particles, molecules and ions of solutes. More strictly speaking, the adsorption or concentration (generally of a third substance) is at the interfacial layer separating two phases. For example, water in contact with air gives an air-water interface; a certain tension

exists at this interface which is spoken of as the water-air interfacial tension and is measurable to a high degree of accuracy. Many substances in the water phase go readily into this interface, that is, they concentrate there, and this surface concentration process is called 'adsorption'. Soaps, flotation-oils, and many other substances dissolved or suspended as small particles in water concentrate in the water-air interface. If water is in contact with a solid such as the walls of a glass tumbler, a water-solid interface exists and it is presumed that a tension exists at this interface, although methods are not available for measuring it. If solid particles are suspended in water, a liquid-solid interface exists as truly as in the case of the water against the tumbler. Certain third substances in the water, in solution or in mechanical suspension, as oils and colloids, may concentrate in this solid-water interfacial layer, as shown later in this paper.

The interfacial tension between two phases, such as water-air, and water-solid, is a definite and specific quantity, and it is different for different substances in contact, and is affected (lowered) in many cases by the presence of a third substance in one or both of the phases.

It is an accepted generality that if the surface-tension or surface-energy of water or any other liquid is lowered, a surface concentration of a third substance has taken place, and, inversely, if a third substance has been adsorbed or concentrated at the surface of a liquid, the surface-tension or surface-energy has been reduced.

Willard Gibbs early worked out the mathematical relationship involved in the above general principle. His simplest equation appears in the form:

$$U = - \frac{c}{RT} \frac{ds}{dc}$$

where U is excess concentration at the boundary surface in grammes per centimetre, c is the concentration of solute in bulk of solution, R is the constant of the simple gas equation, T is the absolute thermodynamic temperature, and s is the interfacial tension. As this expression shows, any substance that lowers the surface or interfacial tension will concentrate at the interface, whereas any substance that raises the tension will be driven out from the interface. This expression has been investigated in several cases and has been found to hold. The formula, however, is of little value because interfacial tensions like that between a solid and a liquid cannot be determined experimentally. But it will be shown later in this paper that undoubtedly adsorption of at least certain constituents of flotation-oils takes place at the surface of certain minerals. Although in the experiments that follow it makes little difference, it is reasonable to suppose that when oil is adsorbed at the surface of solid par-

ticles, both the oil and solids being suspended in water, there is a lowering of the water-solid interfacial tension.

It was the above important principle that suggested the line of investigation outlined in this paper. It is significant to point out that most flotation-oils lower the surface-tension of water, that is, they contain certain constituents or group molecules that do so. *If it happens that the third substance added to a water-solid system is adsorbed at both the water-air and water-solid interfaces, surface-tension measurement on the water should give a scheme for determining the amount of the third substance adsorbed by a unit of surface of the solid phase.* In the experiments that follow later in this paper, it will be seen that flotation-oils (or certain of their constituents) when agitated in water lower its surface-tension. A curve can be plotted giving surface-tension on the vertical ordinate, and oil-water concentration on the horizontal ordinate. It will be presumed that such a curve can be used to determine approximately the amount of a given oil in water; then, by simply measuring the surface-tension of a given oil-water mixture and referring to the curve the amount of oil in the water can be told at once. Any oil, or certain constituents of it, removed from the water by any means, can be detected by measuring the surface-tension of the mixture. This presumption is made the basis for determining the amount of a given oil that is adsorbed from a given oil-water mixture by a unit of a given mineral surface.

SURFACE-TENSION is a manifestation of an inter-molecular force, whether it be due to the electro-magnetic fields surrounding the molecules (Langmuir⁶) or to some other bonding power is not an essential distinction in the theory that follows.

By definition the surface-tension of a liquid is the amount of force required to rupture a film of that liquid one centimetre wide. This force is generally expressed in dynes. For water and other liquids this value⁷ is slightly affected by the nature of the gas in contact with the liquid film.

The surface-tension of water and oil-water mixtures is such a fundamentally important factor in flotation that it is desirable to have accurate and rapid methods for measuring it. It has been determined by Richards and Coombs⁸ to be 72.62 dynes per centimetre at 20°C.; by Harkins and Brown⁹ to be 72.8 dynes per centimetre at 20°C., and by many others. Of these measurements, those of Harkins and Brown are perhaps the most accurate, as every precaution was taken in selecting capillary tubes for the determinations and in making the tests. A variety of methods, of which the most important are the drop-weight, capillary tube, capillary plate-disk, and

vertical-jet, has given values for the surface-tension of water that vary from 72 to 82 dynes per centimetre. The well-known drop-weight method in the hands of the ordinary operator is not accurate,¹⁰ and requires a great deal of time in making the measurement. For the rapid and accurate surface-tension determinations of oils and water required in the present investigations none of the above methods is feasible.

MEASUREMENT OF SURFACE-TENSION. The following apparatus, designed by me, embodies the principles of the apparatus used by Elder,¹¹ Ferguson,¹² and Bhatnagar,¹³ and of the method described by Watson.¹⁴ With this instrument (Fig. 1) the surface-tension of a liquid is determined by measuring the pull required to rupture a film of that liquid of known width. Instead of using a Jolly balance for measuring the tension, as was done by Elder, Bhatnagar, and others, a direct-reading springless balance is used, and instead of using a sphere or a disk to engage the liquid film, a bar or knife-edge of suitable length and design is used. A detailed description follows:

Referring to Fig. 1, it is seen that the apparatus consists of a ring-stand to which is attached near its top a ring *A* suitably machined and provided with small grooves *B* to form bearings for the knife-edge of a swinging member. The latter consists of a 2½-in. cork *C*, an axis *D* machined at either end to knife-edges passing axially through the cork engaging the bearings *B*, and a pointer *E* of suitable length stuck into the edge of the cork wheel nearly perpendicular to its axis. The pointer *E* serves as a suitable weight to be lifted in breaking the film of which the tension is to be determined.

The upright rod, comprising a part of the ring-stand, is threaded for about three inches at its lower end and fitted with a small hand-wheel *F*. The latter may be raised or lowered, and in turn raises or lowers the sleeves *G* and the attached ring *H*. This second ring serves as a support for the watch-glass *J* containing the liquid to be tested.

A scale *S*, placed back of the swinging pointer *E*, is so graduated that each space represents the same horizontal travel of the centre of gravity of the pointer. This scale may be standardized to read surface-tensions on the scale directly in terms of dynes per centimetre.

The cork wheel *C* mentioned above is provided with a small peripheral groove. Over the cork and in this

¹⁰F. L. Perrot ('Jour. Chem. Phys.', Vol. 15, pp. 164-207, 1917) concludes that the classic formula $P = 2\pi r\gamma$, which shows the proportionality between surface-tension and drop weight, should be definitely abandoned; it is only an erroneous approximation. He further states: "A relation which gives the drop weight as a function of the other properties of the liquid is still to be found."

¹⁴'A Text-Book of Physics', Longmans, Green & Co., 1905, p. 192.

groove is hung a No. 50 white cotton thread, to the end of which is suspended an aluminum or silver bar *K* about eight inches below the axis of *C*, and to the other end of which thread is hung a counter-weight. The purpose of the bar *K* is to engage the liquid to be tested; it is described more fully below.

A surface-tension bar six centimetres long is suitable. The small horns *L* (shown in Fig. 2) are to prevent the film of liquid from pulling away from the ends of the bar, as would be the case if the horns were not provided. They are made sufficiently thin and narrow to be quite

as the liquid being tested is lowered further, a liquid film will be drawn out (Fig. 4) and the pointer will drop to a constant reading representing the true tension between the 71 and 75 dyne graduations. The conditions of the two readings are shown in Fig. 3 and 4.

The first breaking or slip does not represent the true breaking-tension of the liquid film unless the body of liquid raised above the surface of the liquid is taken into account and corrected for. This involves the use of a somewhat complicated and cumbersome equation.¹⁵ For water without any correction, it gives approximately 76

FIG. 1. INSTRUMENT FOR MEASURING SURFACE-TENSION

FIG. 1A. ANOTHER VIEW OF THE SAME

negligible, the length of the bar being taken as the length of the straight edge between the horns.

If now the watch-glass containing the liquid to be tested is raised by means of the hand-wheel *F* until the liquid engages the horizontal edge of the bar *K* and is then slowly lowered (see Fig. 1A) the liquid will adhere to the bar, and a bubble film will be drawn out. The tension existing in this film will exert a pull on bar *K* and is measured by reading the number of divisions on the scale through which the pointer has been swung.

It is important to note that in making a determination of surface-tension, two breaking-points, a maximum and a constant reading, will be observed. The first breaking, represented in Fig. 3, will swing the pointer approximately up to the 80 to 85-dyne graduation in the case of water, depending on the thickness of the bar-edge; for a knife-edge the difference is about two dynes. Then,

dynes per centimetre for an edge 0.015 cm. wide. It will vary greatly from this figure, depending on the thickness of the knife-edge engaging the liquid and the degree of wetting of the metal edge by the liquid. If, after careful treatment¹⁶ of the knife-edge so that it will be completely wetted by water, several measurements of the tension required for the first breaking are made in succession, it will be found that tension as measured decreases gradually. This is due to the fact that the degree of wetting of the knife-edge by the water decreases; in other words, the liquid-metal contact angle increases from probably zero to several degrees, and the total

¹⁵Phil. Mag., Vol. 26, pp. 925-34, 1914.

¹⁶I have found that the best way to treat the silver plate or knife-edge to ensure perfect wetting is by rubbing it between the thumb and finger with a little bone-ash and then rinsing it under a running tap.

breaking-pull decreases as the contact-angle increases. It was also found that in the several determinations the point at which the pointer came to rest for the second reading was constant.

This method has the advantage over others, of greater accuracy, due to the fact that the force required to break a straight film several centimetres wide is measured instead of the tension exerted by a width of less than one centimetre, measured around a circular section of a drop, as in the drop-weight method. The accuracy is also in-

FIG. 2

dependent of absolute wetting of the surface-tension bar by the liquid to be tested, as pointed out above. This is not true of other methods, which are dependent on absolute wetting of the disc, capillary tube, or surface engaging the liquid, and therefore are unreliable and more or less impracticable. The method has the further advantage that a determination can be made in a few seconds, as it is read directly from the graduated scale.

FIG. 3

An absolute or theoretical measurement is made by the use of the following equation:

$$ST = \frac{W981}{2L}$$

where ST is the surface-tension in dynes per centimetre, W is the weight in grammes producing the same deflection of the pointer as the breaking-stress of the unknown liquid film; 981¹⁷ is the equivalent in dynes of one gramme, and L is the width of the film ruptured. By the method as above described the surface-tension of water has been determined to be 72.85 dynes at 20°C. This value is in close agreement with the most accurate figures obtained to date, which would seem to indicate that the instrument and method are accurate. It should be pointed out that in a measurement of surface-tension by means of the above described instrument, correction should be made for the pull of the liquid acting on the horns L , as they are actually projecting into the liquid at the time the tension of the film is being measured. One method of doing this is by bringing the dish containing the liquid up to the horns until they just dip into it. The dynes deflection of the pointer is deducted from the

¹⁷This value varies slightly with altitude, but does not affect the value of a reading for any particular locality even in the third decimal place.

previous reading, which represents the film-tension plus the liquid-tension pulling down the horns. Another factor, apparently entirely negligible, is the weight of the liquid film, which presumably is of the order of the thickness of a bubble film.

CONTAMINANTS IN FLOTATION. That certain contaminants are detrimental to flotation is well known, but the cause of their deleterious effect is an interesting problem. One interesting case that has been studied with the aid of my tensimeter is the case of a common flotation-oil on water (see Fig. 5). If we place on the surface

FIG. 4

of clean water a drop of No. 1. Cleveland Cliffs hardwood-creosote oil, it immediately spreads and covers the surface of the water with an oil film presumably one molecule thick. The excess of oil over and above the quantity required to just cover the surface of the water collects into lenticular globules. Now we say qualitatively that the oil spreads if

$$T_{wa} > T_{ow} + T_{oa}$$

where T_{wa} , T_{ow} , T_{oa} are, respectively, the water-air,

FIG. 5

oil-water, and oil-air interfacial tensions. In this particular case, at the instant the oil touches the water and before spreading takes place, $T_{wa} = 72.8$,¹⁸ $T_{ow} = 5$, and $T_{oa} = 32.5$ dynes per centimetre. It can be shown by actual measurement that the addition of one drop of soap solution to the water in a 200-cc. beaker before the oil is introduced will prevent the spreading of the oil. The soap alone lowers the surface-tension of the water to 30 dynes, which is less than $T_{ow} + T_{oa}$ and the oil therefore does not spread but forms in a mass of the shape shown in Fig. 5. In a similar manner the above oil lowers the surface-tension of the water by spreading to less than $T_{ow} + T_{oa}$, and the excess of oil collects in lenticular globules as when the soap solution has been added. Many other substances prevent oil from spreading readily on water, and if they are not flotation agents themselves, they are deleterious to flotation. One of the characteristics of a flotation agent is that it generally, and probably must, lower the surface-tension or surficial energy of water.

¹⁸Although the theoretical measurement of water by the method above described was given as 72.85 dynes, 72.8 is used throughout the rest of the text, as direct readings can be estimated to tenths only, and all other readings are made direct.

A film of General Naval Stores No. 5 steam-distilled pine-oil on water gives the latter a surface-tension of 48 dynes, and a film of Cleveland Cliffs Iron Company hardwood-creosote No. 1 lowers it to 45.5 dynes. The poorest kind of flotation would result if all the bubbles in an ore-pulp had a surface-tension as low as this. Much gangue would float under this condition of extremely low surficial energy.¹⁹ The following table gives the surface-tension of a few flotation-oils as determined with the tensimeter described above.

Surface-Tension of Flotation-Oils

EMULSIONS IN FLOTATION. An emulsion is defined by W. Clayton²⁰ as "a heterogeneous system in which a liquid is dispersed as droplets in some other liquid with which it is only partly or not at all miscible". Theoretically two types of emulsions may exist, according to which liquid is dispersed as drops. It is not definitely known whether the agitation of flotation-oils in water produces an emulsion of oil in water or one of water in oil. Emulsions of pine and hardwood oils with water have surface-tensions much lower than that of pure water. The following table gives the surface-tensions of emulsions of three well-known flotation oils with water.

¹⁹Every operator well knows what happens when more than a certain small amount of oil is added to the ore pulp to be floated. Large quantities of gangue-minerals immediately make their appearance in the froth-concentrate.

²⁰The Modern Conception of Emulsions', Jour. Soc. Chem. Ind., Vol. 38, May 31, 1919.

The above data are plotted in the graph, Fig. 6. It is seen that the surface-tension of the water decreases rapidly with addition of oil up to a certain concentration of oil, when the curve flattens out. It is probable that at this point the amount of oil adsorbed at the surface of the water has reached that of a complete film of oil. The lower concentrations correspond approximately to the quantities of oil used in flotation practice.

The surficial energy of an oil emulsion may be increased by aeration and skimming of the surface as the bubbles burst, a portion of the oil being removed by surface concentration or adsorption at the water-air (bubble) interface. Other substances in the water may, however, interfere with this process. An oil or other agent that cannot be thus removed is, from the point of

Fig. 6

view of this theory, a poor flotation agent. *The soluble oil and oil droplets may likewise be removed by agitating the emulsion with certain minerals such as sulphides.*

THE TESTS. Emulsions were prepared by agitation of the oil with 100 to 200 cc. of water. A motor-driven soda-fountain drink-mixer was used as agitator, in most cases considerable foam being produced by the agitation. Any surface-tension measurement made on the emulsion before all the foam had disappeared was not reliable, and before check measurements could be obtained it was necessary, after the dissipation of the foam, to pour the emulsion back and forth several times from one beaker to another. Several measurements were made on each emulsion, observing between each measurement the precaution of pouring back the part tested into the original beaker, and taking a new portion from the whole.

When several emulsions of the same oil-concentration and surface-tension were required, 400 to 600 cc. of water were taken, and, after agitating in the required weight (in. mg.) of oil, they were divided into volumes of 100 cc. each, and poured back and forth into each other several times. It was found that this was the only procedure that would give several emulsions of the same surface-tension.

Before treating the emulsion with any mineral, the mineral particles were agitated with clean water in order

²¹Mr. Elder of the Idaho State Bureau of Mines & Geology has applied this principle to the treatment of slime-tailing from the Coeur d'Alene. He has removed contaminants from the slime that tend to lower the surface-tension of water and has thereby increased the power of the oil to spread on the watery ore-pulp. For details the reader is referred to Pamphlet No. 1 of the Idaho Bureau of Mines & Geology, Moscow, Idaho.

to remove any powdered mineral held at the surfaces of the particles, and to ensure complete wetting by the water. A given number of cubic centimetres of the particles were then stirred or agitated in the emulsion or allowed to fall through it for a specified length of time; one minute being the standard, unless otherwise stated. The same precautions were taken in measuring the surface-tensions of the emulsions before and after treatment.

MINERAL-OIL ADSORPTION. Not all minerals will adsorb oil, and those that adsorb little or none are not easily floatable. The surfaces of sulphide mineral particles adsorb oil from oil-water emulsions quite readily. The amount adsorbed can be estimated by measuring the surface-tension of the emulsion before and after treatment with a given quantity of mineral particles of known size. If we treat a series of emulsions of known oil-concentration and of determined surface-tension with a given quantity of mineral particles of known size and determine the surface-tension of the emulsions after treatment, it is possible to estimate the quantity of oil, or at least the constituents that lower the surface-tension of water, adsorbed by a unit surface of the mineral. The quantity and rate of adsorption are possibly a measure of the floatability of the particular mineral. However, different minerals may adsorb different constituents or group-molecules of the oil. The following table gives the surface-tensions of a series of emulsions of varying oil-concentrations before and after treatment with a given amount of clean galena.

with galena is evidence that the oil, or certain constituents that lower the surface-tension, has been removed from the water, and made unavailable for the purpose.

FIG. 7

FIG. 8

In the case of the hardwood-creosote the 50 gm. of galena used has adsorbed nearly 80% of the five drops of oil added. This indicates that the hardwood-oil is more readily adsorbed by the galena than is the pine-oil. It

Calculation of approximate total mineral surface in 50 gm. (-10 +20-mesh) galena.

Average diameter of particles = 1.21 mm.

Weight of mineral particle = $1.21^3 \times 7.5$ (sp. gr. of galena) = 13.3 mg.

Number of particles in 50 gm. = $50,000 \div 13.3 = 3650$.

Total surface of mineral = $1.21^2 \times 6 \times 3650 = 32,000$ sq. mm. = 320 sq. cm.

These data are plotted in the graphs, Fig. 7 and 8, from which it is possible to calculate the total amount of oil in milligrammes adsorbed per square centimetre of surficial galena surface treated. In the case of the pine-oil more than three (30 mg.) drops of the five used (49 mg.) were adsorbed by the mineral. The fact that the surface-tensions of the emulsions have been raised by treatment

has been found in practice in the Coeur d'Alene region that Cleveland Cliff's hardwood-creosote is one of the best oils for floating galena.

In another test two emulsions of identical oil-concentration (24 mg. in 100 cc. water) and surface-tension (by measurement) were treated respectively with 10 cc. of -20 +28-mesh galena from the Coeur d'Alene, and with

10 cc. of $-20 + 28$ -mesh galena from California. Each mineral-emulsion mixture was agitated one minute. The surface-tensions of the emulsions after treatment were 68.5 and 69.5 dynes respectively in contrast to 50 dynes for the untreated emulsions. From this experiment it appears, if we assume the same amount of surface was exposed to treatment in both cases, that samples of galena from different districts have slightly different adsorptive powers; it is to be expected that the Californian galena, which adsorbed more oil than that from the Coeur d'Alene, would be more floatative. We know from experience that apparently similar minerals seemingly do vary in degree of floatativeness, although frequently the difference in behavior is due to difference in the gangue.

THE RELATIVE FLOATABILITY OF SULPHIDES. It is well known from experience that all sulphide minerals are not equally floatative under given conditions. If adsorption and floatativeness are in any way related, it should be possible to establish this relation by determining the relative adsorptive capacities of different sulphides under given conditions. To test this the following experiment was made.

Five oil-water emulsions containing the same amount of oil (approximately 25 mg. hardwood-creosote) and having the same surface-tension (by measurement), namely 49 dynes, were prepared. These were treated with 8 cc. of $-20 + 28$ -mesh particles of the following minerals:

No. 1 emulsion was treated with galena from the Coeur d'Alene.

No. 2 emulsion was treated with sphalerite from Missouri.

No. 3 emulsion was treated with chalcopyrite from Globe, Arizona.

No. 4 emulsion was treated with chalcocite from Butte, Montana.

No. 5 emulsion was treated with clean quartz.

The surface-tensions of the emulsions after treatment were respectively as follows: 56.5, 52.0, 54.0, 54.5, and 50 dynes. These data are plotted in Fig. 9.

This experiment demonstrates clearly that under a given condition different sulphides have different adsorptive capacities for flotation-oils, and that there is a close relation between adsorptive power and floatability. It has been my experience that the relative floatative properties of the above minerals are in the same relative order as the adsorptive powers shown above. Further, there is at least a coincident relation between the adsorptive powers of minerals and their molecular weights. Of the above sulphide minerals, galena has both the highest molecular weight and the highest adsorptive power. Sphalerite has the lowest molecular weight and is seen to have the least adsorptive power. Of course, this may only be a coincidence. Quartz, of course, is not a floatable mineral, and its power to adsorb oil is seen to be very small; it has raised the surface-tension of the emulsion only one dyne.

ADSORPTION AND SIZE OF MINERAL PARTICLE. If minerals adsorb oil, as the above tests show conclusively, the

quantity adsorbed should be in proportion to the total amount of mineral surface exposed. To test this premise the following experiment was made: Four emulsions, each containing four drops (23 mg.) of No. 1 Cleveland Cliff's oil in 100 cc. of water were made up. Each had a surface-tension of 50 dynes by determination. One of these was treated with 6 cc. of galena particles passed through a 14-mesh screen and remaining on a 20 mesh screen, one with 6 cc. of $-20 + 28$ -mesh galena particles, one with 6 cc. of $-28 + 35$ -mesh galena, and one with 6 cc.

FIG. 9

of $-35 + 48$ -mesh galena. The surface-tensions of the emulsions after treatment were respectively as follows: 51.0, 53.0, 54.3, and 57 dynes. The total milligrammes of

FIG. 10

oil adsorbed is 3.06, 6.12, 7.65, and 10.75 respectively. The amount of oil adsorbed per unit of surface is 0.091, 0.118, 0.113, and 0.068 mg. per square centimetre respectively. This is a reasonably close check when it is considered that quantity of oil adsorbed is a function of mineral surface and oil concentration, as seen in the table that is given in Fig. 10. This experiment indicates clearly that the amount of oil adsorbed increases as the amount of mineral surface increases. This is perfectly natural and serves as a reliable check on these experiments. In flotation it is therefore to be inferred that the amount of oil used should be in proportion to the size of the mineral particles to be floated, to the percentage of floatable mineral surface, the contents in the ore, and the amount of water used in the pulp.

TEMPERATURE AND ADSORPTION. Ore-pulps to be treated by flotation have in practice been heated before treatment in several instances. To determine if adsorption of oil

by mineral is affected by temperature, the following experiment was made: Three emulsions of hardwood-creosote oil in water were made up, each contained 22 mg. of oil and had a surface-tension of 50.7 dynes. No. 1 emulsion was treated with 6 cc. of (-20 +28-mesh) galena particles at 20°C., and No. 2 with 6 cc. (-20 +28-mesh) galena particles at 50°C., and No. 3 was run as a blank under the same condition as No. 2, but without the galena. The object in running the blank was to be sure that the heating and cooling of the emulsion was not the factor affecting the surface-tension, since the measurements were all made when the emulsions were at the temperature (20°C.) of the room.

The surface-tensions of the three emulsions after treatment were 53.7, 57.0, and 51.0 respectively. At the room temperature (20°C.) the surface-tension of the emulsion was raised, through treatment with the mineral, from 50.7 to 53.7 dynes, an increase of 3 dynes, or, from curve Fig. 6, equivalent to an adsorption of approximately 7 mg. of oil. At 50°C. the surface-tension of the emulsion was raised from 50.7 to 57.0 dynes, an increase of 6.3 dynes, or equivalent to an adsorption of approximately 11 mg. of oil. The blank test after treatment had a surface-tension of 51.0 dynes, approximately that of the original emulsion, 50.7 dynes, indicating that the heating operation hardly affected its surface-tension. The same temperature increased the adsorptive capacity of chalcocite (Cu_2S) for the same oil over 50%. It would appear from this experiment that temperature is an important factor in flotation. It will probably be found that certain chemicals likewise affect the adsorptive capacity of given minerals for given oils. Experiments along this line are contemplated.

ADSORPTION AND AIR-BUBBLES. That air-bubbles in agitation and mixing of oils with ore-pulp are beneficial in practice is well known. To test this point two emulsions, each having a surface-tension of 48 dynes, by measurement, were treated as follows: No. 1 emulsion in a 100 cc. graduate was treated with 6 cc. of (-20 +28-mesh) galena. The graduate was stoppered with a cork that fitted close to the liquid, thus leaving no air space between the liquid and the cork. No. 2 emulsion in a 100 cc. graduate was treated with 6 cc. of (-20 +28-mesh) galena. The graduate was stoppered so that about one inch of air space was left between the liquid and the cork. In each case the graduate was inverted 24 times, that is, the particles of mineral dropped through the emulsion 24 times. In the first case no air-bubbles were present, in the second case numerous small bubbles rushed up through the emulsion as the mineral particles dropped through the emulsion. The surface-tensions after treatment were 52.0 and 54.2 dynes respectively. This result is easy to explain. When air-bubbles are present in the emulsion, a water-air surface is provided at which oil is concentrated; the particles cut through these bubbles, and as a result there is a better contact of mineral with oil than when no bubbles are present.

SURFACE-TENSION OF BUBBLES IN A PULP. While it is readily possible to measure the surface-tension of oiled

pulp entering a machine, and of the tailing leaving the machine, it would be a little difficult to say just what is the surface-tension or the water-air (bubble) interfacial tension of a bubble in the pulp during flotation. As thousands and thousands of bubbles are introduced into the pulp, the surface available for spreading of the oil increases enormously and it is doubtless true that where only a fraction of a pound of oil is used per ton of ore treated, there would not be sufficient oil to lower the surface-tension of the many bubbles very greatly, at least not to the extent that the surface-tension of a beaker full of the pulp containing no bubbles would be lowered; therefore a measure of the surface-tension of the pulp entering the machine would not be a criterion of the surface-tension of the pulp-air bubble, and the pulp-bubble interfacial tension is no doubt higher than can actually be measured.

SUMMARY AND CONCLUSIONS. The fact that adsorption of oil at a water surface is accompanied by a lowering of the surface-tension or surface energy of the water has been made the basis for determining the amount of an oil or oil constituent that is adsorbed by a unit of mineral surface. Almost all flotation-oils lower the surface-tension of water with the oil content. For any particular oil a surface-tension oil-water concentration curve can be made; then from a surface-tension determination of water containing a particular oil the amount of oil in the water can be ascertained approximately. It will, therefore, be evident that if an emulsion or mixture of a given oil in water and of a given surface-tension be treated with a specified size and number of particles of a given mineral, and the surface-tension of the oil-water mixture measured again after treatment, the amount of oil adsorbed by a unit surface of any mineral can be determined.

Probably only certain constituents or molecules of the oil are active in lowering the surface-tension of water, and probably only certain constituents are adsorbed at the surface of the mineral, and the method therefore may give only a rough estimate of the amount of oil adsorbed. This is being made the subject of further investigation.

To carry out an investigation where numerous measurements of surface-tension had to be made, it was necessary to develop an instrument with which accurate and rapid measurements could be made. The instrument described above, in the hands of a trained operator, is capable of giving accurate results, and a measurement can be made in less than one minute.

ACKNOWLEDGEMENTS. I wish to acknowledge my indebtedness in this work to Robert B. Elder of the School of Mines, University of Idaho; for the many ideas and suggestions that have come to me through discussion of the problem with Mr. Elder; to Francis A. Thomson, the Dean of the School of Mines, and Director of the Idaho State Bureau of Mines & Geology, for his early appreciation of the significance of the possibilities of the method of study herein described; and to A. M. Piper, of the State Bureau of Mines & Geology, for his careful scrutiny of this paper.

REVIEW OF MINING

SURPLUS OF REFINED COPPER NOW ABOUT 728,000,000 LB.—CURRENT OUTPUT 34,000,000 LB. MONTHLY

W. F. Bartholomew, of Tucker, Bartholomew & Co., says of the status of copper: "There is no use disguising the fact that stocks of copper are not being reduced as rapidly as was expected when the leading copper producers shut-down their properties. There is available in this country 728,000,000 lb. of refined copper and if we include stocks in the refineries still in process the total surplus of copper will figure up close to the billion mark. Even this, however, is a reduction of 200,000,000 lb. since the first of the year, but we are only just beginning to feel the effects of the shut-down of the mines. Consumption of copper in this country last year was in excess of 1,250,000,000 lb., but consumption in the United States this year will do well if it amounts to one-half of last year's total. Stocks have not been much reduced the last few months because of the large refinery production, but at the present time only eight properties are now producing, the rate of output being 34,000,000 lb. per month.

"Mines in the United States are now down to 11% of normal production, while South American properties are operating at 46%. Accordingly little matte is now coming to refineries and a steady reduction in stocks should be apparent from now on. A monthly production of 34,000,000 lb. is making the market, for the companies producing this copper are selling it as fast as produced, and while the big selling agencies are not forcing sales the small independent producers are selling at 12½c. In view of this situation, one must take an optimistic view of conditions, for within the next year there should be a demand for every pound of copper above ground in addition to that which the present producers are turning out; when the future is sufficiently clear for the big companies to resume operations it will take six months for their copper in volume to reach the market."

TEXT OF THE CLAIM-ASSESSMENT ACT

Following is the exact text of the bill of Representative Carl Hayden of Arizona providing for the changing of the 'assessment' year for mining claims:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section 2 of "An Act to amend sections 2324 and 2325 of the Revised Statutes of the United States concerning mineral lands," approved January 22, 1880, be, and the same is hereby, amended to read as follows:

"Sec. 2. That section 2324 of the Revised Statutes of the United States be amended by adding the following words: 'Provided, That the period within which the work required to be done annually on all unpatented mineral claims located since May 10, 1872, including such claims in the Territory of Alaska, shall commence at 12 o'clock meridian on the 1st day of July succeeding the date of location of such claims: Provided further, That on all such valid existing claims the annual period ending December 31, 1921, shall continue to 12 o'clock meridian July 1, 1922.'" The bill was passed by the House of Representatives on August 1 and is expected to pass the Senate at an early date.

HOISTING ENGINEERS AT TONOPAH VOTE TO END STRIKE

The strike of the hoisting engineers at Tonopah, in effect since April 16 when the engineers' union refused to accept a daily wage of \$5.75, a reduction of 75c. from that previously in effect, was ended on August 5 by a vote of the engineers.

It is reported that the vote was thirteen for, and six against, resumption of work under the new wage. Every former employee will find employment, it is stated, as the Tonopah Mining Co. made no effort to fill vacancies caused by the strike on April 16, either in its mine or mill, and other mines awaiting forces are the Rescue Eula, Midway, Monarch, Jim Butler, California, Brougner, Gold Zone, and Klondyke leases. The West End is the only large mine of the district that refused to combine in the reduction of wages ordered almost four months ago and is still paying the old scale.

Under the scale of wages ordered by the operators in the spring, machine-men in the mines receive \$5.25 per day and shovelers \$4.75. In the mill conveyorman, filter operator, mill laborer, oiler, pipe-fitter's helper, and solution-helper get \$4.75; crusherman, batteryman, repair man, fireman, pipe-fitter, refineryman, solution-man, tableman, and tubemill man receive \$5.25. It is believed that the other organizations will follow the lead of the hoisting engineers in declaring the strike off.

NEW RAILROAD FROM ROGERSON, IDAHO, TO WELLS, NEVADA

The Interstate Commerce Commission at Washington, D. C., has issued a Certificate of Permit for the construction of a railroad from Rogerson, Idaho, to Wells, Nevada. This road will be about 85 miles in length, connecting with the Oregon Short Line at Rogerson and the Southern Pacific and Western Pacific at Wells. The road will afford direct rail haul from the Salmon River mining region to the smelters near Salt Lake City, reducing the distance between mines and smelter at least one half. Heretofore all shipments have been made by truck, 40 miles to the railroad and thence by a long haul to the smelters. One company is said to have ready for shipment a quarter of a million tons of ore now lying on the dump. The ores are chiefly valuable for their silver and copper, the deposits so far as developed to date resembling those of Butte, Montana, it is said.

EXCELSIOR IRON COMPANY GIVES OPTION ON DEPOSITS OF IRON ORE IN UTAH

Growing interest among Eastern capitalists and steel men in the rich iron-ore deposits of Utah is indicated by the announcement that J. R. Walker, through the Excelsior Iron Co., has given Eastern interests an option on his iron-ore holdings in Iron county, the option setting a purchase price on the land at \$4,000,000.

Mr. Walker declines to comment on the matter further than to verify the authenticity of the report. The Walker holdings are understood to constitute one of the larger individual pieces of land in the iron fields. It is understood that

other negotiations respecting other similar holdings are under way, and that the chances are that but a short time will elapse before definite development will be started. The activity of railroad surveyors in the southern part of the State is linked in some circles with the interest in the iron-ore development.

D. C. JACKLING GIVES VIEWS ON THE PERIOD OF STAGNATION IN COPPER MINING

D. C. Jackling spent several days in Salt Lake City recently, en route from Yellowstone Park, where he enjoyed a brief vacation. When asked his opinion as to the future of copper mining, Mr. Jackling stated that the international situation has an important bearing; that adjustment of conditions in foreign countries to such a degree as to restore the demand for the use of copper abroad is the key to the situation, or at least one important factor; and that the demand for copper will follow the demand for other raw materials. As to how soon the copper properties under his direction would resume operations, Mr. Jackling stated that early resumption cannot be looked for with any degree of optimism; the situation may be summed up as being neither a question of weeks nor years, but a question of months. As to how many months no one can say. He stated that no plans have been made for a resumption at any of the properties as yet, although the Utah Copper undoubtedly will be among the first of his group to resume operations.

ALASKA

Hyder.—Both the concentrating and cyaniding departments of the new mill at the Premier mine are said to be giving complete satisfaction. It is expected that the first lot of concentrate will be shipped during the first week in August, and that the value of it will be close to \$100,000.

ARIZONA

Bisbee.—Members of the 'congress', elected recently by employees of the Copper Queen branch of the Phelps Dodge company, held their first meeting on August 3. A communication from Walter Douglas, president of the Phelps Dodge Corporation, was read to the congress by G. H. Dowell, general manager of the Copper Queen branch. Following this Dowell addressed the congress, explaining the work facing the employees under the new scheme; he urged all to co-operate in an effort to bring about a 'square deal' for everyone concerned. Concluding his remarks, Mr. Dowell said:

"The company stands ready and anxious to do everything within its power to make this representation plan a success. We propose to do our whole duty toward our employees in so far as is humanly possible. If the members of this congress enter upon their duties in the same spirit, and if every employee on the payroll will honestly endeavor to do his duty toward the company as the company intends to do its duty toward him, then this representation plan will prove a tremendous success, and the 'square deal' we all so much desire will be indeed a reality."

Following the general meeting of the congress yesterday, the house of representatives held a meeting at which Sam Verran was elected speaker and Robert McCartney, secretary. The senate will meet for organization in two weeks.

Douglas.—Important reductions in rates on smelter products from points in Arizona and from Cananea, Mexico, to Baltimore and New England points by way of New Orleans or Galveston, in connection with the Southern Pacific Atlantic Steamship Lines have been published to take effect September 12. The rate to New England points has been reduced from \$21.10 to \$17.60 per ton and to Baltimore the rate is reduced from \$20 to \$16.50 per ton. These reductions apply only on shipments forwarded by way of the Sunset-Gulf route.

Miami.—Within the past few weeks the Miami Copper Co. has made a shift in its productive operations from its ten-year old No. 4 shaft to a newer opening, known as No. 5. The change was effected without interfering with production. About three years ago the Miami management started a new shaft to relieve the older opening. None of the equipment of the older shaft will be removed, leaving it available should occasion arise. July production was back to around 4,200,000 lb., against but 3,900,000 lb. in June.

Miami has been able to dispose of practically all of the copper it has produced and today is one of the few, if not the only company, now operating at a profit. The bulk of its sales has been for export in which business the company comes into direct competition with the Copper Export Association, of which it was at one time a member.

Tombstone.—Prospects that have not been worked for 20 years are being re-opened in this district. The Bunker Hill company has started one of its compressors for the benefit of lessees in the vicinity.

George Kitt and associates, of Tucson, who have a lease on the State of Maine property from the Bunker Hill company, have just completed a two-mile pipe-line to connect with the main line of the Huachuca Water company, to furnish water for their cyanide plant and for the hoist. They have already started working the cyanide plant on a large stock of ore that was on one of the dumps. Kitt was here last week to inspect the work that is being done and was well satisfied with the showing already made.—H. C. Harsha, of Bisbee, who has a lease on the Cummings property adjoining the Ivey-Critchley lease, has uncovered a good sized body of ore containing lead and silver.—Roger Saunders and the Giacomini Brothers are at work on a claim leased from the Bunker Hill company, near the Oregon, and have already opened some small bodies of silver-manganese ore that promise to lead into larger bodies.

CALIFORNIA

Allegany.—New equipment is being installed at the Rainbow mine now controlled by a group of mining men from Grass Valley. The mine was formerly a rich producer, but the vein was lost and work was discontinued. Exploration is now directed to the other side of the 'horse' that intercepted the lode.—The Sixteen-to-One company is installing a 20-drill compressor preliminary to extensive underground exploration.

Auburn.—F. Moss has a force of men engaged at the Blue Eyes mine, situated six miles east of Last Chance. A 1200-ft. adit is being extended through lava beds in search of rich channels.—A compressor has been installed at the Glen mine, situated near Miller's Defeat. The company is exploring a narrow channel in which 'pay-dirt' is now being mined at two points 2000 ft. apart.

Caliente.—Carl W. Chilson and J. O. Perclval operating the Royal Flush mine have opened a quartz vein at a depth of 90 ft., assays from which average \$32.22 in gold. The full width of the fissure has not yet been determined.

Jackson.—Production from the Argonaut mine is increasing. Rich ore is coming from the deep workings, particularly from the 4900-ft. level. Damage resulting from the fire and flood has been repaired.

Placerville.—The Golden Unit company has completed the construction of a mill at the old Argonaut mine, near Greenwood.—It is reported that the districts surrounding Kelsey, Diamond Springs, and Eldorado, all tributary to Placerville, are being actively prospected. Several sales of small properties have been consummated recently.

Redding.—The three important copper companies in Shasta county asked for a reduction in the assessment of their mines, aggregating \$1,089,304. The Board of Equalization granted reductions totaling \$457,500. The Mountain

Copper Co. asked that the assessment on the Iron Mountain mine be reduced to \$50,000. The equalizers fixed the valuation at \$350,000. The United States Smelting, Refining & Mining Co.'s Mammoth group of mines was reduced from \$449,060 to \$275,000; its Sutro mine from \$58,000 to \$40,000; and its Keystone mine was allowed to remain at \$32,000. The company's improvements were reduced \$88,920. The Balaklala Copper Co. asked that the assessment on the Balaklala mine be reduced from \$262,160 to \$43,875. The equalizers thought \$175,000 was fair.

Shoshone.—The Paddy Pride, through Patrick Miles, superintendent, has bought from the Goldfield Consolidated 500 ft. of air-pipe and 1000 ore-sacks. The air-pipe will be placed in the 420-ft. lower tunnel, from which a 65-ft. raise is in a 7-ft. width of lead-silver ore assaying 0.04 oz. gold, 61.06 oz. silver, and 73.20% lead. The full width of this ore has not yet been determined. Shipments will be started when the air-pipe is in place, according to Miles.

Sierra City.—Energy is being bent toward the develop-

Cyclops tunnel-level by the Midwest M. & M. Co. and two shifts are breaking ore for delivery at the company's Iron City mill, a plant of 75 tons capacity. A third shift is to be employed within 30 days. Flotation concentrate from the 'Brown' process is reported to average 0.64 oz. gold, 105 oz. silver, and 11.65% lead.

Cripple Creek.—The Vindicator Consolidated company is extending a lateral north-west from the 19th level of the Golden Cycle shaft, corresponding to what will be the 20th level of the Vindicator No. 2. The objective is the present terminal point of the Roosevelt deep-drainage tunnel, some 3000 ft. distant. Negotiations looking to extension of the tunnel are under way, but no agreement has as yet been reached. The Vindicator is now raising water from the Golden Cycle, but with the tunnel-connection completed this heavy cost will be eliminated. Development of the rich shoot on the Little vein at the 2000-ft. depth on the Vindicator continues from the Cycle cross-cut, and, with the raise through to the Vindicator shaft, sinking will be started in

A Recent Photograph of the A. S. & R. Co.'s Smelter at Murray, Utah, Showing the New Stack

ment of a 'pay-shoot' following the discovery of a new vein in the Sierra Butte mine. The vein was found on the foot-wall side of the old orebody; cross-cuts are being driven in search of possible quartz.

Sonora.—A supply of good ore in sufficient quantity to keep a mill in continuous operation for several years is reported at the Patterson mine. The management has taken steps to equip the property with a thoroughly modern mining and milling plant. The foundation for a 20-stamp mill is under way. A new office building is also in course of erection. The installation of a 150-hp. hoist is planned, as it is desired to have a hoisting equipment that will make possible the sinking of the shaft to the depth of 2000 ft. The development of the Patterson by the present operating company has been under the direction of J. L. Whitney.

COLORADO

Aspen.—The Richmond Hill M. & M. Co. is planning resumption of work on the Little Annie mine following tests on ore made by J. T. Terry, flotation metallurgist of Leadville. The mill will be re-equipped and placed in charge of Terry.——Aspen business men have formed a leasing company to operate the Eclipse group on Castle creek and have forwarded supplies. Veins containing zinc, lead, copper, silver, and gold are exposed in shaft and tunnel workings.

Blackhawk.—A 52-hp. hoist has been installed at the

ore as the rich vein extends to the shaft station. The extension of the tunnel rests with other companies owning property in the Bull Hill area, who are expected to contribute to the general cost, estimated at \$30,000. The Vindicator company, however, will extend the deep lateral to its end-line at its own expense. The Vindicator at the present time is draining the Bull Hill area, and it feels that property owners should contribute toward the tunnel extension through other than Vindicator holdings.

Montezuma.—Ore assaying between 400 and 700 oz. silver per ton has been opened in a tunnel on the Berry group at a depth of 1250 ft. Five tons, rich in ruby silver, will be forwarded to the Arkansas Valley smelter at Leadville for treatment.

Salida.—The Parks-Davis Chemical Co. of New York has purchased the Ohio and Colorado smelter in this city for a consideration reported at \$400,000. A cash payment of \$150,000 was made in Denver when the deal was closed on August 1. The Parks-Davis company controls the Raleigh mine in the Salida district and its ore containing arsenic, lead, zinc, and products used in the manufacture of drugs will be treated at the smelter.

IDAHO

Coeur d'Alene.—W. A. Williams, of Spokane, recently cut in his prospect in the Pine Creek district a stringer of ore

as wide as his hand that assayed \$47 in silver and lead. He made the discovery in an open-cut only 14 ft. below the surface.—Payment for the first carload of ore shipped from the Sidney mine showed a net value of about \$30 per ton, which means that a 50-ton car has a net value of \$1500. The ore that is being shipped is practically all taken out in the course of extending the two drifts.—A bond has been taken for a reported consideration of \$80,000 on the Terrible Edith mine, two miles above Murray, by H. A. Morse, a mining engineer of San Francisco. It is a lead and zinc property that was extensively worked for a good many years previous to the War. Shipments of more than \$100,000 worth of ore have been made in past years and the property has 3000 ft. of underground work. A lower tunnel will be driven.

Fairfield.—Six-horse teams are hauling mill machinery to the Walton mine. G. R. Collins, general manager, says he has bought a sawmill to cut mine-timbers and timber for ore-chutes; he believes the company will be producing concentrate within 60 days. Spokane men are interested.

MISSOURI

Joplin.—Persistent rumors that prominent Eastern capitalists have combined to buy into the Tri-State field of Missouri, Kansas, and Oklahoma during the present slump in prices continue to emanate from mining headquarters in Joplin; the activities of agents of these interests lend strength to the belief that this is true. It has been understood here that one of the largest companies recently gave an option on all its holdings, including four concentrating plants, and it is believed here that the option will be closed. A few of the richer mines continue steady operations, and production from them is quite as large as any time in the past. One of the significant developments at present is the sinking of the new shaft by the Chanute Spelter Co. on the land west of the Hartley tract. The shaft is going down more than a quarter mile from the Hartley mill, but it is understood it is the plan of the Chanute company to handle the 'dirt' from the new shaft in this mill, using a long surface tram. This is interpreted as marking the tendency of the times to avoid building new milling units. A cheering feature is the news that slab zinc has been sold for export; this seems to prove that prices have reached a level where no more zinc will be imported.

MONTANA

Butte.—The Anaconda company, in a drift on the 2800-ft. level of the Gagnon mine, has opened a deposit of ore that is rich in copper glance. Whether or not the ore is in one of the silver veins of the Alice group is not known. If this is the lower extension of one of the silver-zinc veins the development is of the utmost importance.—The new discovery of the Anaconda company will also serve to direct the attention of the Davis-Daly company to its Mt. Moriah and New Era claims that are situated in the same part of the district. The Davis-Daly company expects to reach the 750-ft. level, with its Hibernia shaft, within 60 days. A cross-cut 700 ft. long will then be driven to explore the vein.—The Butte & Superior company is rapidly approaching the point at which the copper-bearing vein already found on the 2050-ft. level should be entered on the 2200-ft. level. The shaft has now reached the 2600-ft. level.

NEVADA

Argentite.—The shaft at what is known as the Sanger-Taylor property at Argentite, formerly known as Cow Camp, has been sunk to a depth of 100 ft. and a drift is being driven at this depth. The ore, 4 ft. wide, is of "very good grade," according to Taylor. Sixteen men are employed in building a six-mile road to the claims, and when this has been completed machinery will be moved to the shaft. All work to date has been done with a windlass. The claims

were optioned recently by a company controlled by the Wattersons of Inyo county, California.

Ely.—The Ely Northern Copper Co. has opened a deposit of copper ore 43 ft. wide that assays 5.42% copper. The property on which it is operating is owned by the Boston & Ely Consolidated Mining Co.—S. Herbert Williams has secured a bond and lease on the property of the Ely Revenue Copper Company.

Goldfield.—The Goldfield Development Co. at Gold Hill is drifting east from the bottom of the new 200-ft. shaft; the farthest west of the ore-shoots of the tunnels should be cut in about two weeks. There are two tunnels, driven by former owners, the upper 500 ft. long and the lower, which reaches a depth in the vein of 270 ft., 700 ft. long. Both are drift tunnels. Three ore-shoots are said to be exposed in them, one 140 ft. long, another 160 ft. long, and the third has been opened for 20 ft. in the lower tunnel. The ore contains copper, silver, and gold, with the first increasing as depth is gained. The vein is 14 to 70 ft. wide.

Donald and Giles, Florence lessees, recently made their second shipment, 60 tons of \$140 ore. They have been doing development work, but are nearly ready to resume stoping. The next shipment is expected to be several tons of rich ore they have sacked.

Mina.—The Simon Silver-Lead Mines Co. has acquired control of the Kirk-Simon Smelting Co., at Harbor City, California. The plant is being re-modeled to treat the zinc flotation concentrate from the new mill here. Zinc oxide will be the product of the Kirk-Simon plant. The situation near tidewater will be advantageous in marketing the product.

Peavine.—The Standard Metals Co. is employing two shifts at its mine and mill. Two grades of concentrate are being produced; one containing silver and lead; the other, gold, silver, and copper. Production is at the rate of 90 tons of concentrate per month. The shaft will be sunk to the 500 point, as indications on the present bottom level (300-ft.) are excellent.—According to C. H. Dennison, manager for the Wedekind Silver Mining Co., the drift on the 100-ft. level has been advanced 127 ft., disclosing a vein from 3 to 6 ft. wide.—At the Black Panther drifting in both directions is being done on the 300-ft. level.

UTAH

Alta.—David Phillips, manager for the Alta Tiger Mining Co., reports that at a distance of 65 ft. up a raise which is following No. 1 fissure, along the contact of the black and gray lime, five feet of ore was cut. Assays show \$3 in gold, 20.8 oz. in silver, and 8.1% lead.

Eureka.—Exceptionally good progress is being made in the sinking of the Water Lily shaft at the Chief Consolidated mine by Walter Fitch, Jr., mine contractor. During the first ten days, the three-compartment shaft was sunk a distance of 135.5 ft. Progress is now being made at the rate of about 16 ft. per twenty-four hours, using three shifts. Unless exceptionally bad ground or a heavy flow of water is met, Mr. Fitch expects to establish a new record for shaft sinking. The shaft will be sunk to a depth of at least 1000 ft. as a preliminary step toward the development of the extensive holdings of the Chief Consolidated in the eastern part of the Tintic district.

The work of re-timbering and enlarging the shaft at the Eureka Standard property, adjoining the Tintic Standard, is progressing. E. J. Raddatz, president of the company, is desirous of starting development soon. The property is well equipped and is situated in a promising part of the district.

Lewis Merriman has been elected president of the Tintic-Zenith and Tintic-Union mining companies. It is believed that this is a preliminary step toward the amalgamation of these two companies with the Apex-Standard Mining Co., which is controlled by Mr. Merriman. The holdings of the Tintic-Zenith and Tintic-Union companies embrace more

than 60 claims. Recently additional claims have been patented by Merriman and associates, and if the expected deal goes through, the new company will have one of the largest groups of claims in this district. The Apex Standard has been developing steadily, and while ore in large quantities has not been found, high-grade bunches have been cut from time to time.

Ore shipments for the week ending July 30 totaled 153 cars, as against 156 cars for the preceding period. The Tintic Standard shipped 56 cars; Chief Consolidated, 31; Iron King, 14; Dragon, 10; Victoria, 10; Iron Blossom, 6; Centennial-Eureka, 3; Little May, 2; Swansea, 2; Colorado, 2; Gemini, Bullion-Beck, Eureka Hill, Mammoth, Gold Chain, Sunbeam, 1 each.

Park City.—Shipments of ore from this district for the week ending July 30 totaled 1397 tons, of which the Silver King Coalition shipped 534; the Judge allied companies, 471; and the Ontario, 389. During the previous week, shipments totaled 1273 tons.

Salt Lake City.—Effective August 11, the freight-rate on lead bullion from Utah smelting points to the Atlantic seaboard was reduced from \$22 to \$16.50 per ton. During 1920, the mines of Utah produced 1,343,200 tons of ore, exclusive of the production from the Utah Copper mine at Bingham. Most of this was silver-lead ore, and it is estimated that the reduction in freight on bullion will result in a saving to mine operators of approximately 60c. per ton, or a total saving of more than \$800,000 per annum. Inasmuch as the smelting companies increased their charges when the freight-rate on bullion was advanced, it is believed they will now give the mine operators the benefit of the reduction.

The coal-mining companies of the State report a pronounced betterment in the situation as applying to their products. An average of from 250 to 350 cars of coal per day is being shipped by the mines in Carbon county, most of which is billed to Pacific Coast points. The Denver & Rio Grande road has lately put on 15 additional locomotives to handle the increased traffic between the coal mines and this city.

WASHINGTON

Valley.—Edwin Seaman and his son were plowing last spring when their attention was attracted by a rock, turned up by the plowshare, that looked like ore. Selected samples have shown returns of 29.6% copper, with some gold and silver. The rock that Mr. Seaman considered a nuisance in his field is now said to be the outcropping of a vein that can be traced across his farm. Work done in open-cuts has produced ore of good grade. A shipment of sorted material is to be sent to the smelter.

Kettle Falls.—Assays of ore taken from a vein near Shannon creek, 12 miles west of here, where 30 claims have been located, show \$95 to \$250 in gold and silver on selected specimens, according to reports. Several tons of \$45 ore are said to have been broken.

BRITISH COLUMBIA

Hope.—Work has been resumed on the Emancipation mine, 15 miles from here. W. Fleet Robertson, Provincial Mineralogist, made an examination of this property last year, and in his report stated that the showing justified the bond that the Liberator Mining Co. has entered into with the Emancipation company. The Liberator, the present operators, hope to demonstrate the existence of a large body of milling ore. Most of the gold taken from the property in the past came from small rich off-shoots from the main vein.

New Denver.—It is understood that R. R. Hedley, who recently secured a lease and bond on the Arlington, will ship a

trial lot of ore from the old dumps to the Ottawa mill to be treated; should the experiment be found to be profitable a large quantity of this material is available. The Wakefield mine, at Four-mile creek, is being re-opened. Old-timers in the camp have great confidence in this mine, and believe it will 'come back', as the Silversmith and Queen Bess have done.

Prince Rupert.—W. R. Tonkin of Seattle, has 20 men employed at development work on his property, at Fish creek. The ore is said to be rich in gold and silver on the surface; the object of the development is to prove the ore at depth. A compressor is being added to the equipment at the Homestake mine, at Kitsault glacier, Alice Arm district. This property has been opened extensively by open-cuts and a considerable orebody has been exposed, which is said to average about 60 oz. in silver and 6% in copper. The great drawback to the property is its inaccessibility. It is reported that the syndicate that has been exploiting the oil-shale on Graham Island, one of the Queen Charlotte group, intends to erect a commercial plant to extract the oil from the shale. The company has had a small experimental plant running for some time. Finds of good ore are reported from the Hobo claim, in the Salmon River, and the Patricin group, in the Marmot River districts.

Trail.—The ore receipts at the smelter for the week ended July 21 totaled \$405 tons, the Consolidated company's mine supplying 7977 tons. The other shippers were: Anna, Sloean, 20 tons; Whitewater, Sloean, 36; Gold Hill, Tagham, 42; Knob Hill, Republic, 47; and Surprise, Republic, 283.

Victoria.—Word has been received from John Dresser to the effect that he is on his way to Hudson's Hope to take control of the drilling operations that are being undertaken by the Provincial government to further explore the oil possibilities of the Peace River district. Dresser said he would make an examination of the well that is being bored by the Imperial Oil Co., at Pouce Coupé, on his way to Hudson's Hope. He reports that the Government well, which is being drilled by Lynch Brothers, of Seattle, is down 800 ft. and that the favorable formation should be reached at a depth of 1700 feet.

MEXICO

Durango.—Kenneth A. G. Shearer, prominent English mining man of Guanacavi, is going to develop the Tamesis mines in the Hacho arroyo near the Aurora and Marzlufur mines. Reinaldo Avila, operating in the Inde district, has filed on the vacant ground contiguous to the gold and silver mines Tres Varones, El Repecho, and Constancla. Jesus Gonzales has filed on a group of 14 pertenencias in the San Diego district south of the Refugio mines. Alejandro Rodriguez, representing Juan A. Gallardo, has located several new claims in the Hualzar mountains near the city of Durango. Some good specimens of gold and silver ore have been taken from shallow workings.

Mexico City.—The production of metals in Mexico during the twelve months ended in June is given as follows in kilos (one kilo equals 2.2 lb.): Gold, 10,420; silver, 922,212; copper, 46,056,900; lead, 121,434,066; zinc, 14,363,075; mercury, 77,229; antimony, 1,572,376; graphite, 2,911,529; tungsten, 34,917; tin, 1588; arsenic, 1,198,806; and manganese, 838,624.

Mexico has abolished the export duty on silver, the law having already gone into effect.

Zacatecas.—The mining agency at Concepcion del Oro has registered three new filings this week. One of them is for a group of six silver-copper claims in the San Pedro de Ocampo district, to be titled under the name of Le Reina de San Pedro. The property is situated near the Naranjera and San Francisco de los Muertos mines. Another location is made by Jose R. Zamora in the Mazapil copper district,

consisting of two promising claims. The third, to be called the San Antonio del Ojo del Agua, is located by I. G. Puente, associated with several other mining men. The group is composed of nine claims which lie contiguous to the old Zacatecas, Flor de Maria, Morelos, and other patented claims in the Sierpe district. J. R. Dyer and associates have re-located the old Anexas de Zaragoza mines in Los Muertos mountains under the name of Tenochitlan.

ONTARIO

Kirkland Lake.—The Wright-Hargreaves is now operating on a larger scale than any other mine in the district, the mill treating about 150 tons daily. Stopes have been opened up in several parts of the mine but the mill is kept going mainly on development ore. Small steel balls are to be substituted for pebbles in the tube-mills, as the ore is found to be harder than the pebbles.

A circular issued in London by the Kirkland Lake Proprietary (1919) states that work on the Tough-Oakes and Burnside properties has shown developments of a most satisfactory character particularly by the location of a payable vein west of the main north and south fault on the Tough-Oakes. Details are given of a scheme for the reorganization of the Canadian Sylvanite Company. It has been arranged for the Kirkland Lake Proprietary to subscribe jointly with an American group of financiers for the 80,000 unissued shares of \$5 each of the Sylvanite and reorganize that company with a total capital of \$3,000,000 in one dollar shares, of which \$2,000,000 will be issued to the shareholders in the present Sylvanite Co. in the ratio of five shares for one. The remaining 1,000,000 shares are to be held in reserve giving the Kirkland Lake Proprietary and the American group the option of acquiring 500,000 shares each over a period of two years.

The Teek-Hughes proposes to increase its milling capacity from about 100 to 160 tons per day and has given orders for a ball-mill, tube-mill, and classifier, with accompanying equipment.—At the Wood-Kirkland eight veins have been discovered by surface work within 200 ft. of the shaft.

The Lake Shore has been enabled to resume dividend payments and has declared dividends of 2% payable August 10 and 2% payable November 10.

The Ontario-Kirkland is making a new permanent shaft near the mill-site by raising from the 400-ft. level to connect with a shaft started from the surface.

At the Queen Lebel a good vein 8 ft. wide has been cut; assays yield satisfactory results.

Larder Lake.—The Crown Reserve of Cobalt is exploring its claims near the Canadian Associated Goldfields and has uncovered a vein 40 ft. wide, 20 ft. of which carries fair gold content.

Matachewan.—Work in this field is being held up by reason of transportation difficulties and lack of power.—At the Thesaurus mine mining equipment has been installed and operations are being carried on by steam-power.

Porcupine.—Following a meeting of the directors of the McIntyre it was officially announced that work would be started at once on an addition to the mill of 500 tons capacity, bringing the total daily capacity up to 1000 tons. It was also given out that the station on the 1625-ft. level is completed; the sinking of the shaft will now be resumed. The recent find now being developed on the 1375-ft. and 1500-ft. levels is stated to be "a body of high-grade milling ore lying to the south of No. 7 vein on the contact between the quartz-porphry and the basalt".—The Allied Porcupine Mines is unwatering the workings of the Three Nations, which it recently took over together with other properties.

South Lorrain.—The electric motor which drives the 20-stamp mill of the Keeley mine was recently burned out, necessitating the temporary closing down of the plant.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

David Cole is at Cananea.

Leon A. Perret is at Yokohama.

J. M. Callow was here last Tuesday.

Alvin B. Carpenter is at Mexico City.

S. R. Guggenheim is at Island Park, Idaho.

Howard D. Smith has returned to New York.

S. Herbert Williams was at Denver last week.

Richard Roelofs, of Colorado Springs, is at the Fairmont hotel.

J. Nelson Nevius has returned to Pasadena from Silverhorn, Nevada.

H. G. Young has returned to Montreal, Quebec, from Michipicoten, Ontario.

Walter Fitch Jr., mining contractor of Eureka, Utah, is in southern California.

H. C. Carlisle, engineer for the Tonopah Mining Co., is here from Philadelphia.

L. D. Ricketts is making a tour of inspection and was at Globe, Arizona, last week.

V. N. Franchic, on his return from Panama, has gone from San Francisco to Great Falls.

G. M. Ponton, of Montreal, was in San Francisco on his way to Ensenada, Lower California.

H. Foster Bain, Director of the U. S. Bureau of Mines, is expected in San Francisco next month.

Britton B. Gottsberger has been elected secretary of the Mining and Metallurgical Society of America.

Robert H. Hawley, superintendent of the leaching plant of the Utah Copper Co. at Magna, Utah, has resigned.

Stephen Birch, president of the Kennecott Copper Corporation, was at the Nevada Consolidated Copper Co.'s properties recently.

Gaichi Yamada, assistant Professor of Metallurgy at the Kyoto Imperial University, Kyoto, Japan, has been visiting mining districts in Utah.

Luis Ibanez Velasco has resigned as assayer for the Compañia de Petroleo 'El Aguila', at Tampico, Mexico, and has gone to Berlin, Germany.

L. O. Kellogg, superintendent for the South American Development Co., at Portovello, in Ecuador, is spending a holiday at Carmel, California.

H. S. Mullikan, special technical assistant, U. S. Bureau of Mines, will visit the Mines stations at Los Angeles and Berkeley, about the middle of August.

Alejandro Lacasa, metallurgist and mining engineer of Spain, who has been three months in the United States investigating various metallurgical processes, was in San Francisco last week.

OBITUARY

Lawrence Greene, managing director of the Clayton Mining & Smelting Co. of Idaho, died at his home in Salt Lake City on July 30, after an illness of four years. He was born at Ottawa, Canada, on January 25, 1865. In 1885 he went to Clayton, Custer county, Idaho, and began working for the Clayton Mining & Smelting Co. He was with the company for more than 20 years, working up to the position of general manager. He then resigned, and moved to Salt Lake City, where he engaged in other business, but was still retained by the company as managing director. He is survived by his wife and four children, one of whom, Godfrey C. Greene, is a metallurgist for the Nevada Consolidated Copper Company.

THE METAL MARKET

METAL PRICES

Zinc-dust, cents per pound.....	9

EASTERN METAL MARKET

(By wire from New York)

August 8.—Copper is inactive but steady. Lead is quiet but firm. Zinc is dull and unchanged.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

GOLD IMPORTS AND THE RESERVE SYSTEM

The Federal Reserve Bank says in commenting on the volume of gold imports the past few months and their relation to the Federal Reserve system:

"When Congress passed the Federal Reserve Act one of its major purposes was to provide elasticity of currency and credit. Gold was to form the sole reserve behind Federal Reserve notes, the new elastic currency, and was to be the principal reserve behind reserve bank deposits, which increase as bank loans and deposits expand. Congress did not specify in dollars or percentages what these reserves should amount to, except as to minimum requirements, and even these were not absolutely rigid.

"In practice the reserve ratios of the system pass through a wide range, but thus far have never fallen to the minimum below which they cannot go without payment of penalty. These minimum percentages are 40% of gold behind notes and 35% of gold and lawful money behind deposits. In the middle of July 1920 gold behind all Federal Reserve notes in circulation, after allowing for required reserve against deposits, amounted to 40%, and in July 1921 to 80%. The corresponding ratio of New York Reserve Bank rose from 46% to more than 100%.

"It is from holdings of reserve banks that gold is mainly withdrawn at times when it is flowing away from the country, and it is into reserve banks that gold mainly goes when the flow is toward the United States. Consequently, if the outflow coincides with a heavy credit demand, as between July 1919 and July 1920, reserve ratios rapidly decline; if the inflow coincides with a lessened credit demand as at present, reserve ratios rise rapidly. In either case, flexibility of the Federal Reserve system permits adjustment to demands for credit from industry, commerce, and agriculture, and former adverse consequences of heavy gold movements, such as a sharp curtailment of credit when gold flows out, are minimized.

"Supply of gold in the United States is now at its highest point, though not much higher than before restrictions on export of gold were removed in June 1919. During the last 12 months, because of conditions without precedent in any like degree, there has been a great flow of gold from Europe. The total stock in the United States on July 1 was \$3,223,000,000, estimated about 10% of the world's stock.

"The gold recently received came largely from private sources, and served mainly to reduce foreign indebtedness to this country. Gold holdings of most of the European central banks are larger than before the War. The Bank of England has more than half as much again, and even the German Reichsbank has nearly as much gold as before the War. That does not mean necessarily that the entire stocks of gold in those countries are greater than before the War, because the tendency has been for the gold to be assembled in central banks, where it should serve as the basis for credit and issues of currency."

MONEY AND EXCHANGE

Foreign quotations on August 9 are as follows:

Sterling, dollars: Cable	3.66%
Denard	3.66
Francs, cents: Cable	7.80
Denard	7.84
Lire, cents: Demand	4.42
Mark, cents	1.24

Eastern Metal Market

New York, August 3.

Inactivity is general in all the markets. Price changes are more pronounced in copper while in the other metals prices are almost stationary.

Speculative copper, and metal in weak hands, has weakened the market without stimulating buying.

On most days the tin market has been inactive but prices have been firm.

Lead is more freely offered, but quotations are steady.

There is still little life to the zinc market.

Antimony is a little lower.

IRON AND STEEL

The latest transactions in steel products have shown substantially the same low prices as were revealed in the previous week, with here and there a new decline; sheets and plates apparently are the lines of least resistance, says 'The Iron Age'. Willingness to name a price that will take the business, where the tonnage is larger than usual, is still the attitude of the leading steel companies, albeit sentiment is better in view of a somewhat larger volume of orders and inquiries and the feeling that improvement in other industries will soon be felt in iron and steel. Some publicity has been given to what is called a new and lower schedule of prices by the Steel Corporation, particularly on bars, plates, shapes, tin-plate and sheets, but the figures given have been the basis of ordinary transactions for more than a fortnight.

The general average of steel-mill operations in the Pittsburgh, Youngstown, and Wheeling districts is somewhat higher this week, due largely to the starting of departments that have been idle, in some cases, for several weeks.

The returns of July pig-iron production confirm the week-to-week reports last month that iron and steel works operations were declining. In the 31 days of July, 864,555 tons of pig-iron was made. This was at the rate of 27,889 tons per day, or more than 20% less than the June rate of 35,494 tons per day, the June total being 1,064,833 tons. Not since December 1903, nearly 18 years ago, when 846,695 tons was produced, has the country seen so small a pig-iron output as last month's. July showed a net loss of 7 active furnaces, 69 being in blast August 1, with a capacity of 28,175 tons per day, against 76 on July 1, representing a daily capacity of 32,195 tons.

COPPER

There is practically no improvement with the turn of the month. Some claim that the weak and speculative copper has disappeared, but others deny this and freely admit that the electrolytic copper market is down to 12c., delivered, which means 11.75c., New York. Demand is light and is easily satisfied with the cheaper offerings. Not all sellers, particularly the large producers, will sell as low as 12c., and some refuse to quote under 12.50c. The unsettlement in exchange has put a damper also on foreign buying, which just now is light. It is interesting, however, to note that Germany is now our heaviest buyer, having ranked first in the last five months previous to June when she took more than twice as much as any other country. For the 11 months ended with May, this year, Germany had taken 27% of the total exports which compares with 33% before the War, or in 1913, when she was preparing for war.

TIN

There is not much activity. On most days the market has been featureless and buying absent. On one day the middle of last week about 200 to 250 tons was sold, mostly future shipment from the Straits, which was sold both to consumers

and dealers. The market on yesterday and Monday was quiet and nominal at 26.75c. and 26.50c., New York, respectively, for spot Straits, largely because the London market was closed on Monday, due to bank holidays. Previous to that buying in London was fairly heavy. Quotations there yesterday were only 5s. per ton higher than a week ago with spot standard at £158 10s., future standard at £160 10s., and spot Straits at £159 per ton. Statistics for July show deliveries into consumption to have been 1521 tons, with stocks on July 31 at 1721 tons, and in landing at 800 tons. Imports for the first 7 months have been 10,418 tons as compared with 31,613 tons to August 1, 1920.

LEAD

The situation is little changed. Independent producers are offering a little more freely at 4.40c., New York, or 4.20c., St. Louis, but the demand is not equal to the supply at these levels, which represent the market. The leading interest continues its quotations of 4.40c., New York and St. Louis, for wholesale lots for early delivery.

ZINC

There is improvement reported in the market. Some prime Western in wholesale lots for August delivery is obtainable at 4.20c., St. Louis, or 4.70c., New York, but most producers in this market are apathetic and asking 4.25c., St. Louis, or 4.75c., New York, for the little business presented.

ANTIMONY

Antimony is stagnant but prices are only a little lower at 4.60c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

The leading producer has not changed its quotation for virgin metal, 98 to 99% pure, which stands at 24.50c. f.o.b. plant, for wholesale lots for early delivery. Importers are asking as low as 21c. per pound, New York, duty paid, for the same grade of foreign aluminum.

ORES

Tungsten: There is no business. Quotations are nominal at \$3 per unit and upward, depending on the grade of ore and other conditions.

Ferro-tungsten is obtainable as low as 55c. per pound of contained tungsten, but there is no demand.

Interest centres on the proposed tariff and it is figured out that the new bill imposes a duty of about \$9 per unit on ores and 72c. per pound on the tungsten contained in alloys.

Molybdenum: Quotations are nominal in a quiet market at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: The market is devoid of business and asking prices are unchanged at 22c. per unit, seaboard, for high-grade ore.

Manganese-Iron Alloys: There are inquiries for about 700 to 800 tons of ferro-manganese and about 350 tons has been sold. Quotations are about \$70, delivered, for the domestic alloy and \$70, seaboard, for the British. One representative of a British producer has a limited tonnage which he is holding at \$70, delivered. Spiegeleisen is quoted at \$26, furnace, with sales of carload lots reported.

Ferro-silicon, 50%, is now obtainable as low as \$60, delivered, and there are inquiries for a few carloads.

Exports of Mexican oil from Tampico during the third week of July totaled 1,000,000 bbl., of which 650,000 was crude. This is about 20% of the normal rate.

*In addition there was a payment of \$600,000 made on July 3, 1919, to the Kerr Lake Mines, Ltd., as a return of capital to the stockholders of that company.

†In addition \$1,652,260 was paid by individual companies prior to the amalgamation in 1914.

Book Review

Concentration by Flotation. Compiled and edited by T. A. Rickard. John Wiley & Sons, Inc., New York. 692 pp., ill. For sale by 'Mining and Scientific Press'. Price, \$7.

The material in this book is a compilation of articles that have appeared in the 'Mining and Scientific Press' during recent years. Five of these, constituting 'The Flotation Process', were published in book form in 1916; 17, comprising 'Flotation', appeared in 1917. The new book contains, in addition to the 22 articles already published in book form, 18 later contributions to the subject, thus bringing the study of flotation up to date, and providing, in convenient form, a compendium of the best literature that has been published on the technology of the process.

The book offers evidence, if such were needed, of the large amount of material on flotation, technical and technological, that Mr. Rickard has contributed to current literature. In the present treatise he is responsible for the original production of about 25% of the contents; the range of subject matter is extensive; the versatility of the editor of the 'Mining and Scientific Press' will be apparent to every reader. A glossary of scientific and technical terms serves as an introduction; this will help the engineer or the layman to understand the fundamentals of this most important development in metallurgy. Mr. Rickard's contributions to the book include chapters on the history and the principles of flotation, the flotation of gold and silver mineral, flotation practice of the Utah Copper Co., the smelting

of flotation concentrate at Garfield, together with a critical and masterly, though condensed, exposition of flotation litigation, freed, as far as is possible, from legal jargon. Other chapters deal with the theory of flotation by a number of writers and investigators, including O. C. Ralston, Glenn L. Allen, E. E. Free, C. Terry Durell, H. Hardy Smith, Robert J. Anderson, Joel H. Hildebrand, Will H. Coghill, H. P. Corless, and C. L. Perkins. A chapter by James M. Hyde discusses the testing of ores; another is contributed by O. C. Ralston and Glenn L. Allen. E. J. Atckison describes the flotation of semi-oxidized silver ore. The cyanide treatment of flotation concentrate is dealt with by Charles Butters and J. E. Clennell; and the recovery of copper from flotation concentrate by leaching is discussed by Percy R. Middleton. Current practice at well-known mills is described by James Hebbard, R. T. Mishler, Hallet R. Robbins, W. E. Simpson, Edwin T. Henderson, R. J. Harvey, A. H. Heller, and C. C. Freeman. W. Shellshear contributes a chapter on preferential flotation; and H. Hardy Smith, one on the cascade method. The book concludes with a résumé of literature on the theory of flotation, with critical notes, by H. R. Adam. Both the editor and the publisher are to be congratulated on the appearance of an attractive volume, which will serve as a reliable text-book to all who are in any way interested in the flotation process.—A. W. A.

Spiegeleisen, as made in Europe, may contain from 10 to 35% of manganese, states an Imperial Mineral Resources bulletin. British and American standard spiegeleisen contains about 20% of manganese.

T. A. RICKARD, Editor

GOLD mining is generally considered to be a vicarious occupation for engineers, but the St. John Del Rey Mining Company can boast an average length of service of the heads of departments now at Morro Velho of 23 years. Is this a record?

WALTER LYMAN BROWN, who is representing the American Relief Association in Russia, is one of the mining engineers to whom the War gave an opportunity for large public service. He used to be stationed at Rotterdam as distributing agent for the Commission for Relief in Belgium, and in our issue of September 21, 1918, he wrote an article describing the good work done by himself and his associates under Mr. Hoover.

IN spite of the destruction by enemy action of over 13 million gross tons of sea-going vessels between August 1, 1914, and November 11, 1918, and the loss through marine hazards of an additional 2,390,000 tons during the same period, the world's mercantile tonnage afloat is today greater than it would have been had the average rate of increase for the ten years prior to 1914 continued since that date, according to the 'Commerce Monthly'. Estimates of tonnage now afloat indicate a total in excess of 60 million gross. Afloat—yes! But too many of the ships are merely affording a safe anchorage for barnacles. The new director of the U. S. Shipping Board asks for a subsidy of \$300,000,000 for the coming fiscal year. The sum mentioned is as good a guess as can be made at the present time, he says; a bigger sum may be needed. All in favor of unlimited taxation, say 'aye'.

NEGOTIATIONS, initiated by a committee of the American Mining Congress, for the purpose of arranging a settlement of the flotation litigation have come to an abortive conclusion, for the present at least. It appears that the Minerals Separation people asked \$15,000,000 for their patent rights, whereas the representatives of the copper companies, their principal opponents, offered \$5,000,000. Some slight concessions were made, we understand, but in the end the Minerals Separation people refused to take less than \$11,000,000, and the other side declined to raise their offer to any such figure. This is a pity, for we believe that it is greatly to the interest of all concerned, and of the mining

industry, that litigation should be settled out of court. If Mr. Lloyd George and Mr. De Valera can meet and reconcile their differences we do not despair of Mr. John Ballot and Mr. D. C. Jackling being able to do so likewise if both could be caught in a conciliatory mood.

SUCCESSFUL mining engineers realize that their professional work involves no circumscribed routine; it embraces a little or much of almost every branch of human endeavor; there is hardly a phase of industrial, social, or scientific advance that is not viewed with at least some degree of interest. The failure of the mediocrity is due generally to mental insularity, and to a lack of appreciation of what has been done in other industries, as well as in his own particular 'line'; the success of the professional man often follows an acquisitiveness for information on any or every subject, and a cultivated ability to discard the useless, to discern at sight the valuable or the interesting, and to classify the information so that it is readily available. We are not directly concerned with the distillation of oil from shale, but we realize that the subject is interesting and important; therefore in this issue we reproduce an article by Mr. David E. Day, of the Day Company of this city, because the problems discussed are somewhat similar to many that occur in some phases of metallurgy, and because of the author's lucid presentation of principles, facts, and conclusions—a circumstance that points to careful investigation, and gives the promise of technical success.

STATISTICIANS have estimated that, without the use of modern machinery, several billion slaves would be needed to keep the wheels of industry turning at their accustomed rates; but it is obvious that, although machines may displace manual labor, manual labor could not do the work that many machines are doing today, however many billion of workers were put to the task. In this issue we publish several pertinent comments by Sir Robert Kotzé, Government Mining Engineer in the Transvaal, on the relations between fatigue and the atmospheric conditions in mines. His conclusions are shared by many, for he reminds us that improved economy of exploitation and better health will result if we are economical of the muscular labor of those who work underground and amid conditions that are not always healthful. Substitute as far as possible, he says,

the energy of the machine for the muscle of the laborer. This advice has been anticipated to a great extent during the last decade in countries where labor of all kinds is costly, but its logic has yet to be realized in many places where labor is considered cheap. We would, however, emphasize the point that the so-called cheap labor is usually most expensive in the end. It is not generally realized that against the cheapness of the native labor on the Witwatersrand must be debited the heavy levies that are met by the companies for the maintenance of the various phthisis sanatoriums, for payments of compensation, and on account of the money that the industry loses in training and teaching men who afterward develop a debilitating or fatal disease. Apart from the economic aspect of the matter, it must be admitted that, so long as it remains a factor to be considered, the white plague is a reflection on the social side of the mining industry. So long as miners' phthisis occurs as a result of honest labor, so long will it be impossible, as it is with war, to count the expenditure in terms of dollars and cents. If atmospheric conditions underground are bad, then let them be remedied by mechanical ventilation; if ideal conditions are impracticable of attainment, then let it be realized that muscular labor should be reduced to a minimum, and machine methods utilized to the full.

Wages and Costs

The chronic economic disagreement between capital and labor, between employer and employee, is not likely to be settled until both are prepared to deal justly by one another. In our mining districts at this time there are many strikes and rumors of strikes in consequence of the effort to lower the rate of wages in accordance with the decline in the cost of living. Obviously, as wages were increased in consequence of an advance in the cost of living, it is just that they should be decreased when the economic tide recedes. Among the efforts made sincerely to adjust the matters equitably is the arbitration now in progress at Grass Valley, California. This gold-mining centre is one of the most attractive and prosperous of the communities that came into existence in the early days—seventy years ago. By reason of the persistent productivity of its mines, especially the Empire and North Star, the people of Grass Valley have escaped many of the disagreeable vicissitudes incident to gold mining; owing to its pleasant climate and agreeable position, on the western slope of the Sierra Nevada, it has become a place of homes; it is a community of English-speaking people, including many Cornish; it has not, like many other industrial centres, been invaded by immigrant aliens. The principal mines have long been under the same management, and it is a management of educated and experienced engineers, not lacking the humane feelings to be expected of a properly educated man. Therefore the relations between the managers and the men have been on a friendly and self-respecting footing. Here, if anywhere, one might expect that the wrangle between the two sides in the economic struggle

could be adjusted reasonably; and that here at least the problem of deflation would be settled fairly and peaceably. This is what is happening. On July 1, 1920, wages in the district were raised to \$5 per day for miners and \$4.75 for shovelers, an agreement to that effect for one year being made between the mine operators and the Mine Workers Protective League, which is the name of the local union. To this organization the mine operators, as represented by the managers of the mines, have raised no opposition; every employee is a member of it, even the shift-bosses, assayers, and master-mechanics. The mines are run on the 'open shop' system, but no man is prejudiced by being a member of the union or by not being a member. The men are not discouraged from joining the union nor intimidated if they do. Last year the union undertook to force a man—he happened to come from Australia—to join them; he refused to do so, but said that he would have joined if they had "come to him decently about it"; when coercion was attempted, he balked. We know of no locality where the 'open shop' is more fairly observed; in many other places it is a sham. At each mine there is a grievance committee; and the management "likes it", I am told, because the committee often makes excellent suggestions and the men usually choose good men to represent them.

So far, so good. It will be agreed that the conditions do credit to all concerned. The North Star began operating at one-third capacity on May 1, 1920. By July of that year the principal companies were employing a full force, but it was soon found that the men were not working efficiently; they loafed; they had been spoiled by the war-time spirit, which was expressed by grabbing at high wages without giving a fair return in labor, a spirit that was reduced to an absurdity in the naval dockyards and munition factories, while the pseudo-workers were being coddled as heroes of the home line of defence. How pitiful all that insincerity seems now! One man at Grass Valley, for example, bragged that he could "get by" on two cars per shift, whereas the usual task for a shoveler underground is six or seven cars per shift. It includes some sorting. In consequence of this state of affairs the mines could not be operated profitably. They began to lose money. At one mine it was found necessary to cut down the force to one-third and supply ore to a third of the mill only. By selecting ore of a little better grade, the manager was able to earn a profit. He found that a third of the crew broke enough ore to supply half the mill. Even at the higher wages the efficiency of the select men was such that the ore could be exploited more cheaply than before.

After several conferences between the operators and a wage committee from the League, in an attempt to agree upon a wage-scale to replace the one to expire on June 30, it became apparent that no agreement could be reached. Therefore on June 10, 1921, a letter was sent to the League, or union, stating that the best offer the companies felt justified in making was a reduction in the wages of miners to \$4.25. At the same time it was announced that shovelers would receive 50 cents less, in-

stead of 25 cents less, than a miner's wages, because it had been discovered that many men preferred to be 'muckers' at 25 cents less, rather than do the drilling. The League refused to accept the offer. The North Star began to discharge its force preparatory to stopping all work. On July 1 all the men not already discharged failed to come to work except the pump-men and hoist-engineers, who remained at the old rate of wages. The League called them out, but did not call a strike, because that could not be done without a secret vote and the leaders had good reason to believe that such a step would not be endorsed by the rank and file, who, it is believed, were willing to come back on the new terms. Moreover, as the companies were still paying the old scale of wages, there was no excuse for a strike. So the pump-men were "requested to quit". They did; but two of the companies brought men from the outside, so their pumps were not stopped. The Empire prepared to stop pumping. Within a few days the League suggested arbitration, and this the companies accepted forthwith on the mutual understanding that a settlement should be made on the basis of the cost of living, that is, the wages as of July 1, 1920, were to be reduced in proportion to the decrease in the local cost of living since that date, with the proviso that there should be a difference of 50 cents between the wages of miners and muckers in any event. On July 15 the men went back to work at the scale of wages proposed by the operators, leaving the final settlement to their leaders. Those representing the miners believed that there had been less decrease in the cost of living at Grass Valley than elsewhere. Each side was to appoint an arbitrator and the two were to select a third. Unfortunately the chief spokesman for the miners caused himself to be selected. He is Mr. William Southcott, who for twenty years has worked as hoist-engineer at the North Star mine; he is Mayor of the town, and a power in the Methodist church. The companies selected Mr. Allen P. Matthew, a lawyer of San Francisco and connected with the firm that is retained by one of the companies. The company side was represented in the negotiations by Messrs. George W. Starr of the Empire, Arthur B. Foote of the North Star, and John A. Fulton of the Idaho-Maryland mine. A difficulty has arisen in the selection of the third arbitrator—the arbitrator, in effect—because Mr. Southcott has nominated a gentleman who is in politics, and politics, of course, is the death of economic fairness, because, in this case, for example, the men represent many votes and the managers only a few. To us it seems obvious that the third arbitrator should be one entirely detached, somebody not living in the district and in no way connected with any of the disputants. A professor of economics from one of the two principal Californian universities would seem to us a person suitable for the purpose. Here we advert to the objection suggested in the selection of Mr. Southcott. A partisan, especially one committed already to a fixed point of view, is unlikely to be a fair arbitrator. The companies did not select one of the mine managers, nor should the leaders of the union have forced their chief on the board

of arbitration. Meanwhile we note that the mine managers, after a detailed examination of the statistical evidence available, satisfied themselves that the decline in the cost of living since July of last year has been 28%, whereas the other side argued that it was not more than 12%. A decline of 15% would justify, statistically, the reduction of wages to the schedule suggested by the operators. It is difficult, of course, to establish an average cost of living, because the household budget varies in different homes; moreover, the prices at which things are being retailed today are by no means uniform even for standard articles, because some merchants are trying to sell old stocks bought at war prices for as little less as possible, whereas others can sell cheaply the cheaper stocks purchased by them since the unpleasant process of deflation began to go into effect. However, where there is a will there is a way, and we feel confident that three fair-minded intelligent men can decide justly. If it can be done anywhere, it can be done at Grass Valley, provided always that exuberant egoisms are kept in subjection. We await the result with keen interest, for a satisfactory conclusion should serve as an example for other mining districts.

Discussion

This department is lively again this week. We are glad to hear from our friend Mr. Edgar Hall, who quotes an incident of prospecting in Australia to suggest how silver may be melted out of an ore, as in the story of Potosi. Both Mr. Allen H. Rogers and Mr. W. Spencer Hutchinson write on the licensing of engineers, and we are pleased that our mention of the matter has elicited their opinions on so important a subject. However, as Mr. Rogers affirms, we gave the findings of the American Association of Engineers for what they were worth; we offered, and we offer, no argument for or against licensing in general; we admitted that the problem "is beset with difficulties". In discussing the work of corporations and unrestricted partnerships we had in mind those cases in which the opinions of professional engineers, with a specialized knowledge and experience of a particular branch of technology, and no commercial interest in the venture, have been over-ridden to make room for the pseudo-technical reports of such unrestricted corporations as we attacked, the partners of which are vitally interested in the profits to be made, not out of the technical or economic results of their recommendations, but out of the initial cost of the plant or the initial expense of erection. American industry has suffered by such aggressive action against the privileges of practising engineers; technical failures have resulted, thus throwing discredit on skilled technicians as well as upon that branch of the industry in which they are interested. The professional engineer, whose advice might well have been considered in the first instance, must often remain idle until, in desperation, he accepts a salary for work in the field. We would, of course, demur from any suggestion that a firm such as the General Electric Company should

be prevented from issuing plans for the erection of its own machinery. But Mr. Rogers must realize that professional advice is often given gratuitously by a commercial firm that is interested in the erection or sale of plant equipment and in connection with a problem of which none of its staff has any special knowledge. If the State control of engineers is to be considered, it is obvious that such encroachments on the activities of practising professionals ought to be checked. The Mining & Metallurgical Society of America, we understand, is considering the question of licensing in all its aspects; we again suggest that its researches should include a study of the matter to which we have drawn attention. The revision of the mining law is the subject of three letters. The first is by Mr. John F. Davis, who speaks as a lawyer conversant with the troubles arising from the effort to reconcile the facts of nature with the acts of legislation. However, it is fair to say that the square location is not the idea of a "theoretical engineer"; we do not know who first brought it forward, but as adopted in the proposed revision it is fathered by a number of mining engineers of wide experience and high reputation. We are glad that Judge Davis quoted the paragraph from his own previous statement on the subject, because it holds good today and is an excellent summary of the matter told in convincing language. Mr. Emile M. Renaud also does not like the revision, and he gives his reasons for not liking it, the first of which is the difficulty of adopting cardinal lines when locating a claim. To this, prospectors generally seem to object. Mr. Renaud clings to the right of location by discovery, because the omission of this requisite plays into the hands of mere speculators, who can plaster the ground adjacent to a discovery with claims on which no prospecting has been done, and so cause the discoverer to lose part of his reward. On the other hand, Mr. Frank L. Sizer comes to the rescue of the revisers, although he also objects to an annual tax of \$5 per acre in lieu of the \$100 worth of assessment work. A plea for the tariff on quicksilver is made by Mr. A. E. Kellogg. Mr. Algernon Del Mar returns to the discussion of the question of chloridizing roasting, and insists that zinc chloride is not a solvent for silver chloride. We would like to hear from a few more mining engineers on the subject of the proposed revision of the mining law; it is a matter of great importance and is well worthy of thorough discussion before it is decided by Congress.

Industrial Co-operation

A plan to promote better relations between the Phelps Dodge Corporation and its employees at the Copper Queen branch, and to provide means for the prompt and equitable settlement of complaints and grievances, has received the approval of over 80% of the men, and has gone into effect. In many respects the proposals are novel, the plan having been modeled on the Constitution of the United States, under which, as the general manager, Mr. C. H. Dowell, states, "every individual is given an opportunity for advancement according to his ability

and determination, and every citizen is given a voice in making the laws that govern him". The plan was first submitted, by the Employees Conference Committee and the Foremen and Bosses Committee, to the company officials for approval. The Board of Directors and the general manager sanctioned the plan, provided it could be shown that, as determined by secret ballot, the majority of the employees were in favor of it. The result of a vote, as already mentioned, was overwhelmingly in the affirmative.

The plan provides for the establishment of a House of Representatives and a Senate, as well as executive and judicial departments. All employees will have a voice in the adoption of rules and regulations that govern their work and the conditions of their employment. The employees will vote by ballot, every six months, to elect representatives from among themselves. No employee who is classified as a foreman or a boss, or whose duties are of a supervisory nature, is allowed to vote for, or to serve as, a representative. The House chooses its own officers, appoints its own committees, adopts its own rules, and punishes its own members; it assembles once a month, and may be convened at other times by the head of the Executive Department. Members of the Senate are chosen from the foremen, the bosses, and those whose duties are of a supervisory nature, but no superintendent or head of a major department is allowed to act; like the House of Representatives, the Senate meets once a month, appoints its own committees, adopts its own rules, and punishes its own members. Provision is made for freedom of speech in both assemblies; no penalizing is permitted. Measures only become effective when they have passed both Houses of Congress, and have been approved and signed by the head of the Executive Department. If a measure does not meet with his approval, he returns it, with his objections, to where it originated, when it may be reconsidered or revised. On the other hand, any measure may become effective over the veto of the head of the Executive Department by a vote of two-thirds of the members of each House. Congress may enact legislation dealing with safety rules, the employment and discharge of employees, the allocation of rewards to employees in return for the introduction of economies or improvements, the provision of pensions, and the establishment of benefit societies. A Standing Committee will hear grievances on the part of the men, and will make decisions. Congress will be empowered to pass measures to provide an educational course in mining methods and management, the graduates from which will be considered, in preference to others, for positions of responsibility; it may establish a plan of apprenticeship, whereby the young men in the community may learn a trade; and it may 'legislate' with the idea of facilitating the peaceful settlement of all differences between the company and its employees. The constitution exhibits a broad-minded tolerance in granting the right to work to anyone, irrespective of race or nationality, or membership or non-membership in any organization, the principles of which are not in conflict with the Constitution and laws of the

United States or of the State of Arizona. The company, however, reserves the right to increase or decrease production, or the scale of its operations in any or all departments, without question, and as it sees fit. The head of the Executive Department is the general manager of the Copper Queen branch; his 'cabinet' will consist of the assistant manager, together with the superintendents of the mine, of the reduction plant, and of the concentrator. All measures passed by Congress will be approved or disapproved within ten days after presentation. The general manager, as head of the Executive Department, may make recommendations to Congress, he may convene either or both Houses in extra session, he may attend

tion of the plan emphasizes the fact that all should be interested in corporate affairs. The experiment will be watched with interest. The plan has been based on a sound and logical foundation, the Constitution of the United States. We wish Mr. Dowell, the general manager for the Phelps Dodge Corporation at the Copper Queen branch, and the chief of the Executive Department, the loyal support of his Congress.

Iron-Ore Resources of Europe

The iron and steel industry is a barometer of national progress. The bulletin by Mr. Max Roesler on

OUTLINE MAP OF EUROPE, SHOWING RESERVE OF IRON IN ORE

The circles have been drawn according to the scale shown in the diagram in the right-hand bottom corner, in which the unit circle represents the world's output of pig-iron in 1913 (about 80,000,000 metric tons). The solid centre represents the known reserve; the shaded part, the probable reserve; and the open circle, the possible reserve. A cross indicates that the reserve is less than 20% of the world's output in 1913.

meetings and participate in discussions. He has the power to grant reprieves and pardons. A Supreme Court of three judges will be appointed by him; it will have original jurisdiction in cases in which the constitutionality of any measure is in question, and appellate jurisdiction in cases arising out of grievances between employees and those in authority over them. The formula-

tion of the iron-ore resources of Europe, recently issued by the U. S. Geological Survey, is the outgrowth of a report that was compiled by the Survey for use at the Peace Conference. As the subject is one of general interest, it is fitting that the report should be arranged for publication in convenient form. Although the Conference re-adjusted the political divisions of Europe, it is obvious

that racial antagonisms, class struggles, and divergent economic demands will cause further changes. Sufficient information is available, however, to show the new political significance of the large deposits of iron ore in Europe. The principal changes of ownership that have occurred as a result of the Great War are summarized as follows: The part of the minette deposits that lies in Lorraine Annexée has been returned to France. Of the German bog ores, the part estimated for Posen has been allotted to Poland, together with the small deposit of Triassic ores in that part of Silesia the ultimate ownership of which remains to be determined by a plebescite. The small deposits near Krakow, in Galicia, also go to Poland. The iron ores of Bohemia and Moravia, as well as those of the Szepes-Gömör district, which lies in the Ruthenian country, on the southern slopes of the Carpathians, have been allotted to Czecho-Slovakia. The deposit in the Vares district, in Bosnia, has been transferred to Jugoslavia. The deposits in eastern and south-eastern Hungary (those of Banat and Hunyad being the only extensive ones) are regarded as belonging to a greater Rumania. Poland and Finland, parts of old Russia, are considered as independent. The uncertainty in regard to Poland's eastern frontier and the re-arrangement of the Baltic States does not affect the allocation of the iron-ore reserves of that region, because the unallotted territory contains no ores that are considered as valuable enough to be reported.

The summary shows that, out of a total of 12,405 million metric tons of iron in iron ore, France has the largest reserve, which amounts to 35.2% of the total. Great Britain is second with 18.2%. The Swedish, representing 12.5% of the total, is largely in the form of high-grade ore; the British ores are carbonates and hematite, and are of a much lower grade. The calculation of reserve of ore in Great Britain is complicated by the fact that a considerable proportion of the ore cannot compete with that produced abroad, even if readily available for mining; so that, in spite of the enormous reserve in Great Britain, the use of imported ore is increasing, and the production of domestic ore is declining. Germany comes fourth on the list, with 11.1%; and we are told that she has shown an ability to use her own resources to such an extent that the local pessimists are probably wrong in assuming that her future lies only in agricultural expansion. Spain stands fifth with 5%, but difficulty and expense in transportation, which have been left out of consideration in calculating the reserve, make it questionable whether the whole amount will ever be mined. Central Russia is sixth, with 4.2%; Norway, seventh, with 3.8%; and Southern Russia, eighth, with 2.8%. Belgium, Portugal, Jugoslavia, the Caucasus, Finland, Rumania, Italy, Switzerland, and Bulgaria all have small reserves; Turkey in Europe has some ore; Holland, Denmark, and the Baltic States contain almost none. Mr. Roesler's compilation concludes with a comprehensive bibliography of the literature of the subject, together with a number of excellent maps, one of which we reproduce herewith.

Mexican Labor Problems

Subordinates should be led, not driven; in the War it was the officer who knew that his men were behind him who achieved success. The same attitude should be observed by those of us whose work takes us to foreign countries, and where the personal element is an important factor in the conduct of successful industrial operations. Mr. Alonzo Crittenden makes this point clear in his article on the management of Mexican labor, which appears elsewhere in this issue. The correct attitude for the foreigner to observe in such a country is not an easy one, neither is the best course of action always obvious. The so-called Latin-American is unstinted in his courtesy to the foreigner. To many this appears to be insincere and surfeited; but the attitude is due to a strict and invariable observance of the customs of the country, to which our southern neighbors hold an unswerving allegiance. The foreigner must realize this. In return he must endeavor to combine an equal measure of amiability, for diplomacy's, if not for sincerity's sake, in his dealings with the Mexicans of all classes. If he does this he will be repaid amply. His attitude on matters of administration or operation must be sure and certain; his decisions must be fair, logical, and to the point. He must bear in mind that Mexico, like many other countries, is cursed with a drink habit that befuddles the workers on occasion and is the cause of nine-tenths of the unreliability that is such a deterrent to efficient industrial effort. This condition is inevitable; and allowance must be made for the fact that the *peones* have been permitted a full measure of self-determination in this respect. With one type of foreigner only is a knowledge of the language inadvisable; those who consider the Mexican merely as a machine whose mentality has only reached that stage of development of which it may be said that curses and insults constitute the only suitable form of communication. For such, a linguistic handicap is advisable. In this connection we are reminded of a manager of a small property in northern Chihuahua who refused to learn Spanish. One day, when on a visit underground, he found that the Mexican in charge of the pumps had, with misplaced zeal, stupidly tampered with the nuts of a stuffing-box, and with unhappy results. Being unable to vent his wrath in the language of the country, the manager sent for the book-keeper, who was a fluent linguist. "Tell this — — — —", he said, shaking his first in the face of the erring Mexican. "that if I ever catch him monkeying with this — pump again, I'll pull every — whisker out of his — face." The book-keeper quietly told the Mexican, in understandable Spanish, that the attitude of the *jefe* should be disregarded, and that it would be better in the future for him to restrain his initiative in the matter of machinery alteration until he was surer of the result. The manager, unable to understand a word of the book-keeper's admonitions, thought that his fiery invective had been translated verbatim; and, subsequently, that the improvement in pump-control underground was due to his threats; but the book-keeper knew otherwise.

DISCUSSION

The Discovery of Potosi

The Editor:

Sir—In your issue of April 2, commenting on Prof. Gowland's essay, you refer to the discovery of Potosi by the Indian who stumbled over a stump and fell, and so exposed some bright silver, a story we learnt as children.

Some years ago I had an experience which makes that story probable and intelligible. A small prospect, long since abandoned, from which a few shipments of silver ore had been made in the early days, is situated in the bush at a spot favored by picnickers. During the dry year of 1912 the ground was swept by a fierce bush-fire, which destroyed the timber of the shaft, and the workings collapsed. At the next picnic the children came running in great excitement; they had "found silver"!

Where the heavy hardwood logs had burnt slowly in the dump at the shaft there was much charcoal plentifully spangled with silver. Under the conditions there, at the time, if a lump of hornsilver had been lying at the foot of a stump, the bush-fire might easily have produced like conditions to those which led to the discovery of Potosi.

EDGAR HALL.

Silverspur, Queensland, June 2.

The Evasion of Licensing

The Editor:

Sir—It seems to me that your editorial on this subject in your issue of July 16 was written under a misapprehension. You state that the New York licensing law "permits corporations and unrestricted partnerships to practise irrespective of the conditions of this law. They are exempt". As I read the law, this is not correct. Section 39 k is as follows:

"Corporations or partnerships. A corporation or partnership may engage in the practice of professional engineering or land surveying in this state, provided the person or persons connected with such corporation or partnership in charge of the designing or supervision which constitutes such practice is or are licensed as herein required of professional engineers or land surveyors. The same exemptions shall apply to corporations and partnerships as apply to individuals under this act."

This can only be interpreted to mean that corporations or partnerships engaged in the practice of engineering or land-surveying must do the work by means of licensed engineers in their employ. They cannot practise otherwise as your editorial seems to state.

On the other hand, except for this provision, they may continue to practise engineering exactly as they are doing now. So it is hard to see how the effect of this law will have the result described in the sentence where you say: "Conditions are permitted under which a group constituted in whole or in part of men who are not engineers may violate, with impunity, the codes of ethics that have been adopted by various professional societies for the guidance of their members and for the protection of the public".

Your statement regarding the action of the American Association of Engineers at its recent convention at Buffalo is not in accordance with my understanding of the fact. It is my impression that the A. A. E. is the only organization of engineers that favors these pestiferous licensing laws. Their opposition, as declared in a resolution at Buffalo, has been directed against permitting corporations to practise engineering under any conditions. In this, in the case of the New York law, they were seconded by the Society of Consulting Engineers. If, as I understand it, they had been successful in amending the law in accordance with their ideas, such concerns as the General Electric Co. would have been prevented from issuing plans for the installation of the machinery they sell. It is difficult to see how any manufacturing concern could continue its business under such conditions.

I note that at the conclusion of your editorial you have given the Association's argument in full detail, from which I infer that the information on which your editorial is based has been obtained from that organization. What object they have in misrepresenting the facts I do not know; in fact, their policy of trying to force the system of licensing on the engineering profession seems to me exactly opposed to their declared purpose to promote the economic and social welfare of its members. In this State they did their utmost during the last session of the legislature to get a licensing bill passed, but in this movement they were successfully opposed by the members of the national societies. That they have been successful in so many States is, I think, much to be deplored, but if we are to have licensing laws, I question whether one much better than that of the New York State could be drawn.

ALLEN H. ROGERS.

Boston, July 21.

The Editor:

Sir—Your editorial on this subject in your issue of July 16 seems to indicate your approval of the legislation providing for the registration and licensing of engineers.

I want to tell you of the opposition to such legislation which has developed in Massachusetts. A bill was proposed at the last session of the legislature. It was sponsored by the American Association of Engineers, and that organization was active and insistent in its efforts to get favorable consideration. The Boston section of the American Institute of Mining and Metallurgical Engineers joined with the other engineering societies here in opposition to the bill before the legislative committee. Our efforts resulted in postponement to the next session of the legislature.

We are opposed to any law requiring registration or licensing of engineers, for the reason that there is no public need or general demand, whereas the laws proposed and already adopted in some of the States endangers our business, and the fees required are an unnecessary and offensive tax.

Boston, July 26. W. SPENCER HUTCHINSON.

Revision of the Mining Law

The Editor:

Sir—I have read the letter of J. R. Johnson, of Silver City, New Mexico, published in your issue of the 6th inst., and I most heartily agree with it, and hope the "departmental miners" at Washington will give heed to its wise practical suggestions.

This agitation for the square location is of perennial recurrence. Generally, it is fathered by some theoretical engineer seated in a swivel-chair, who is utterly without any realization of what would be the legal and practical effect of such legislation at this late day. The increasing familiarity of many of our prominent mining men with the square location of Mexico and its results has had much to do with fostering a sentiment in its favor. This recurrent agitation is no new thing. As early as 1880, B. C. Whitman, of Nevada, and Judge Hallett, of Colorado, openly advocated it, and the Public Land Commission urged it upon Congress, while Chief Justice Beatty, of California, and R. W. Raymond, strenuously contended for the extra-lateral right, at any rate until the era of active prospecting should have actually passed away. See Report of Public Land Commission of 1880.

The unanswerable point made by Mr. Johnson is that the practical effect of this fussy "remedy" will accomplish nothing except to make confusion worse confounded by giving us two systems of location instead of one; preserving the extra-lateral right for all past locations and giving us the square location only for future locations.

The idea founded on the tin-bounding of Cornwall and the original lode-claim system of Prussia has strong anchorage in this country. If, possibly under conditions analogous to those that obtained in Prussia at the time, the extra-lateral right shall ever be abolished, then its abolition now would merit consideration. The extra-lateral right is, however, a vested right at present in all lode patents fulfilling the conditions of the present law, and in all the numberless locations duly made under the

lode rules, customs, or regulations. No amendment can take that vested right away. In all lode mines that at present exist where compliance has been had with the condition of substantial parallelism of end lines, the extra-lateral right is indefeasible, unless the abandonment of the possessory ownership by the owner shall throw the mine itself back into the public domain. Any legislation on the subject, could at most, then, only affect future locations.

Mr. Johnson is also right in calling attention to the fact that in order to appreciate the merits of the respective systems themselves the point of view of their advocates should not be lost sight of. Twenty years ago, in discussing that phase of the subject in a historical sketch of the mining law of this State, I called attention to this point, and I have seen no reason to change a word which I then said with reference to it. After discussing various phases of the question at that time, I said:

"After all, no matter how honestly the advocates of the two systems contend, the conclusions reached depend largely upon the point of view. The large mine operator, who buys and opens, but who does not discover or locate, mines, upon whose shoulders falls the burden of the costs of litigation—he, with his lawyers and his surveyors and his experts, usually leans toward the 'square location'. The prospector and the discoverer feels in his every fibre, no matter what fictitious sacredness judicial construction of the statute may have thrown about the idea of the surface, that the lode itself is the only real property, as it is the only thing he has been hunting, and when he finds the lode his desire 'to stay with it till it reaches hell' is a passion that cannot be understood by one who has never owned a lode mine and worked in it, or who has never lived in a mining community. The discoverer is not of the class that has usually had to bear the costs of mighty lawsuits, and therefore he loses no sleep over the possible litigation. And, even if he does take the chance of losing the mine, he is willing to do so with the same cheerfulness with which he spent the greater part of his life on the chance of finding it. As long as the law recognizes his right, he is willing to take his chances of being able to hold on to the lode. He has long learned to look upon mining with the same game philosophy with which John Oakhurst looked upon life: as at best an uncertain game, and to 'recognize the usual percentage in favor of the dealer'."

JOHN F. DAVIS.

San Francisco, August 8.

The Editor:

Sir—I have read the proposed revision of the mining laws, and as you kindly stated in your issue of June 18 that you would be glad to hear from your readers, I venture to submit my views on the matter.

I am always in favor of any progressive legislation, also of any reform that is the good of the greater number, but I am far from being in accord, specially on some points, with the proposed revision initiated by the committee appointed by the Bureau of Mines.

Sec. 5-A, Locating on Cardinal Lines:

That feature of the proposed revision is next to impossible, from a practical point of view. It is absurd to locate on cardinal lines in conformity with the system of public land surveys, even on surveyed land, unless we want to drive the legitimate prospector from the field altogether. It is deplorable that Nature, in creating lodes and mineral deposits, was not accommodating enough to lay them parallel and on cardinal lines in conformity with Uncle Sam's surveys.

To be explicit I will cite instances that demonstrate without a doubt the unreasonableness of the demand that the legitimate prospector locate on cardinal lines. We, right here, are on surveyed land, and two years ago a local mining association ventured to locate a water-right to generate power to run a mill that was being built on the river; and in order to do so, with the application they had to furnish the Water Commission with a survey of the ditch, the points of diversion and distribution, the engineer's field-notes, etc. Their engineer was on the ground with a crew of men; all went on a hunt for a corner-section monument; they hunted for a week, but they did not find one; so finally they concluded to tie up to a patented claim about a mile away. How long would it take a prospector with a four-bit compass in his pocket (as a rule it is as good as he can afford) to find a corner monument? He could not tie to the patented claim, for it was not located on cardinal lines.

Another instance. This spring a railroad company, the Yosemite Valley Railroad, ventured to run a survey up the river for a proposed line. F. M. Woodman was the engineer in charge. With a crew of men, and armed with a transit, maps, and all the guides and references available, after days of hunting and brush-cutting they finally found what purported without a doubt to be a section-corner. Mr. Woodman will verify my assertion. He is connected with the Y. V. R. R. and Yosemite Lumber Co., of Merced Falls, California.

I have been here and owned claims here for ten years. While I knew I was on surveyed land, I did not know the whereabouts of one corner monument in the county. None of my neighbors knew of the whereabouts of such a monument, and some of them had been here much longer. These are samples, and samples of the whole mining country in general. That ought to be enough to convince any sane man of the absurdity of locating on cardinal lines.

Section 5-B, Subject to Limitations:

I fail to see what good it can do to give the right of location without discovery, and I know that in many cases it would do much harm. It is a known fact that there are two classes of prospectors: The Roughneck who does all the original locating in a new area and digs all the first holes, but does not at any time locate anything unless he makes a discovery. If he does succeed in making his prospect attractive it is only a matter of a short time before he will be at the end of his rope and must do something toward getting financial help. There is one course open for him: to sell the control, but by

doing so as a rule he is left to stick around for awhile, then kicked out, or 'frozen out', as it is generally called. That is when the other class of prospector comes in. And to make it short and explicit, let us call this class the Highbrows. It is in this class that the committee of the select few who initiated this proposed revision belong, and it is only for their selfish interest that it should be enacted. The other course for the Roughneck is to take the few paltry dollars that the Highbrow offers him, and for safety as a rule he takes the latter course; he takes the few dollars and settles with the storekeeper and buys a few necessities and then goes to some favored spot to hunt for another prospect.

By all means let us have it that a discovery is a condition precedent to the location of a mining claim.

As the draft reads, I presume that the committee had in mind that possibly in some cases the prospector might venture to do his prospecting for discovery with a diamond-drill. I do not see any objection to that, but let him do his drilling before he locates. The right is given to hold a claim classified as mineral for five years without discovery and then the prospector or locator would have his time extended for five years more, by payment into the U. S. Land Office of \$50 for each acre or fraction thereof. Where is the legitimate prospector that could pay \$50 per acre per year or \$2000 per year in advance? The average legitimate prospector has not enough to buy beans for a month in advance. It is ridiculous.

According to Section 5-G: Final entry and payment shall be made for all mining claims within seven years from the date of the original location. This would compel the prospector to take the few dollars he is offered within seven years or lose all, for very few would have the money for final entry and payment, although he always has the time to represent.

The longer a claim is held before final entry the better it is for the development of the mining industry, for \$100 has to be expended in improvement or development, and as proof I'll say this: I know in the Ubehebe country where there is a group of 14 claims that have been patented for many years on which there is ore that assays as high as 12% copper, besides other values, and they are not worked. The owners own other copper properties and thereby limit the output.

Section 6-B, pertaining to paying the money into the U. S. Land Office in lieu of development or improvement. The only good that could do would be to create a position for three-buckle high-boot man, who probably would get the position for services rendered; or, in other words, to liquidate a political debt, and he could come over and look up a discovery for Mr. Highbrow. Let the amount be expended in labor or improvement; as already stated, Mr. Highbrow doesn't like to dig. Well, Mr. Roughneck will do his digging for him. He needs that money to buy beans and powder to do his own representing.

Section 7, pertaining to lateral rights: I believe that something should be done to eliminate so many lawsuits caused by apex splits, but by enacting a law to that effect we may get rid of one evil only to create another; what

will become of the apex lawyers and expert-testimony men? As a rule in an apex suit both sides are fat financially and they can well afford the expense: and those fellows have to live, somehow, but as I am not fighting the lawyer's battle in this matter, I will let them do their own fighting; it is up to them. There is a law in British Columbia that was enacted in 1896 and seems to have given satisfaction ever since. A full claim is 1500 ft. square and the right of the apex does not extend beyond the vertical planes of the surface lines, but not on cardinal lines in conformity with the Dominion survey, mind you. Why not copy it to the extent that suits us? You may say that we ought to draft our laws without having to borrow from a neighboring country. I think so myself, but not in that select committee of the few, as so far demonstrated at least; but I am more inclined to think that the brain was not lacking so much; they were merely ruled by their sordid selfishness.

As a summary of the whole: there is no improvement in the proposed revision with the exception of lateral rights. Our mining laws are pretty good and fair to all those concerned as they now stand; and if our lawmakers see fit to change the extra-lateral rights to one more feasible and one that would protect the rights of all concerned, good and well. That could be done with an amendment to the existing laws without repealing practically the whole law and be substituted with this narrow and vicious proposed revision as drafted by this select committee of the few. Now, Mr. Roughneck prospector, do your duty and bombard your respective Senators and Congressmen with protests against this vicious proposition. You are in the majority, and every one of your votes counts one on election day, the protests should be so numerous that our lawmakers would not dare to pass the law as drafted; even if they were inclined to be in favor of it. But if you sleep on the job, then do not blame the lawmakers when it is too late, for they are not all versed in the science of prospecting. Therefore enlighten them.

EMILE M. RENAUD.

Coulterville, California, July 10.

The Editor:

Sir—The proposed new mining law does not, in my opinion, deserve the wholesale condemnation given it by W. W. Rush in your last issue, nor do I think that L. I. Manson can be taken seriously when he says "the side lines of all lode-mining claims shall run parallel with the dip of the vein, to its entire depth". Surely, if Mr. Manson has had any experience with a complicated vein system, he must know that this would be an impossible adjustment. The "gold old mining code" can scarcely be said to "have withstood the test of time"; rather I should say that it has been tolerated and will soon be amended so as to meet present-day requirements. I agree with him that the payment of a tax of \$5 per acre, in lieu of assessment work (honestly performed) of \$100 per claim, each year, would be a pernicious change, tending to slow up and even, in some instances, prevent the

development of mining claims, which, at best, is now hampering the mining industry. There is indeed the danger that he senses in Section 13, under B, in regard to the conveyance of lands which are under the control of the Forest Service and it is to be hoped that this feature of the bill will be eliminated.

If the public at large is as suspicious of the mining engineer as Frank P. Davis seems to be (in your issue of July 16) we must be a sealy lot; and Mr. Davis must be poorly advised, if he thinks that the law is to be retroactive in its provisions. In the same issue, the comment of L. C. Denny is intelligent and pertinent, and I hope that such criticisms will reach the attention of the Committee. There is little doubt but what a provision requiring conformity with the public land surveys, for all lode claims, would result in more confusion and overlapping of claim lines.

With underground rights bounded by vertical planes, there should be no necessity for the orientation that is proposed; and this provision will probably be abandoned.

San Francisco, July 30.

Quicksilver

The Editor:

Sir—During the War the Government made frantic efforts and expended vast sums of money to force productivity of quicksilver in the United States, which but few outside the scientific bureaus at Washington knew existed in this country. It developed at the U. S. Tariff Commission meeting held at San Francisco during the last days of the War that America in producing quicksilver could not compete with the high-grade ores and cheaper labor of Austria, Italy, and Spain. In normal times the average cost of producing the metal in the United States was between \$70 and \$75 per flask of 75 pounds. Quicksilver was the only metal that the War Board agreed to protect with a tariff after the War, and that was done for the purpose of impelling the mine operators to put this industry on a permanent basis in developing their deposits.

The greatest menace to the quicksilver industry in this country is the Almaden mines in Spain, which yield mercury from ore averaging about 11%, at a cost of \$16 per flask. The ore-reserves at Almaden are good for 40 years, on a basis of an output of 1000 tons of metal per annum. These deposits are owned by the Spanish government, and operated with convict labor. The entire output of this mine is contracted to the Rothschilds in London at £7 sterling per flask of 75 lb., and this concern has the privilege of regulating the output of the mines.

Why then should foreign concerns—in this case, only one foreign concern, namely, the Rothschilds, who control 74% of the quicksilver output of the world and manipulate the market as they wish, snapping its fingers at those who are trying to develop the industry in this country—be allowed to directly control our prosperity? They are able to produce as much or as little quicksilver

as they like, and thus keep the price where it best suits their needs. They unload their product in this country when the value goes high enough over what they can obtain in Europe. It may be seen, in this wrecking process practised by this concern, that it is the producer in this country who suffers the decline only to have the same conditions repeated after a rise. How can the American people feel that they are benefited by the establishing of free quicksilver? No one pays for it except American industry and we as a people might as well keep the money at home by placing a tariff on quicksilver, stabilizing the market and developing our own resources.

Up to the present time California contributes more than half the quicksilver produced in the United States. Oregon and Nevada have a few producing mines, while Texas produces about a quarter of our quicksilver. The average grade in California and Texas is less than 0.01%, or less than 20 lb. per ton of ore. The Spanish carries 14%, and subsidiary orebodies 0.02½%; the Italian about 0.01%; and the Austrian 0.85%.

The great cinnabar lodes extending from out of northern California into and through southern Oregon average less than 0.01%, but these lodes are rich in chimneys or pay-shoots that produce ore that reduces to as high as 70% in large quantities. The small furnaces and properties during the war period in the Gold Hill district averaged 17%, while over in Douglas county the operators find conditions about the same as here in Jackson county, but less rich in pay-shoots.

Everybody will not admit that a tariff always has the effect of raising prices. If properly applied, it will permit industries to be developed in this country that cannot compete with powerful industries of the same kind in foreign countries; and it is reasonable to believe that a fair percentage of them will reach a point where they can compete. It seems to be regarded as an economical essential that a country should develop and have at its command all its resources. Competition means reduced prices. Let us have competition.

A. E. KELLOGG.

Gold Hill, Oregon, July 14.

Treatment of Zinc-Silver Ore

The Editor:

Sir—I have to thank Mr. D. W. Brunton for his reply to my question whether chloride of zinc is a solvent for chloride of silver, but the question remains unanswered except in a general way. This is not an academic question, but one of practical importance, for we often have mill products that are at present valueless, as for example an oil-flotation zinc concentrate containing from 10 to 50 oz. silver, but too low in zinc for marketing. If zinc chloride were an efficient solvent of silver chloride the

process patented by Mr. Brunton in 1880 might solve the problem. To be specific, we quote from the patent:

"2. In the process of leaching silver chlorides, the method of obtaining a solution of the chloride, consisting of roasting the ore in fine division at a low temperature [with salt presumably] and dissolving the base metal chlorides from the body of the roasted ore and adding this solution to the ore containing the argentic chloride."

To apply Mr. Brunton's method, the roasted chloridized ore is thrown into a vat of water (or brine) when hot. The silver dissolved may be precipitated by metallic copper, sodium or calcium sulphide. In Mr. Brunton's reply he says "that the solvent power of the salt solution was increased whenever the ore before chloridizing contained blende, by the presence of chloride of zinc and incidentally by the chlorides of calcium or potassium". We infer from this that the presence of the blende, which was converted into zinc chloride, increased the solvent power of the salt solution; therefore, in the treatment of a blende concentrate, the zinc chloride would be produced in relatively great quantities, and the salt solution should be very active.

Experiments I have conducted along these lines indicate that pure zinc chloride is not a solvent of chloride of silver; and an economical recovery of silver from an oil-flotation zinc concentrate by this process remains to be proved. I acknowledge that my experiments have not covered the many possible variations in roasting and leaching. The field is a promising one for the student, particularly in relation to chloridizing roasting and chlorination. We know that oil plays havoc with the cyanide process when treating a flotation concentrate until the hydrocarbons have been completely oxidized; but, theoretically, the carbon left in an oil-flotation concentrate after roasting at a low temperature should have no detrimental effect on the subsequent leaching with salt or hyposulphite, but it may.

The widespread use of the flotation process, particularly in regions remote from transportation, has given rise to new conditions; and it may be that these old processes, which were economically unfitted for the treatment of ores, may be of use for treating a small bulk of concentrate. Silver chloride dissolves in alkaline chlorides $\text{Hg}(\text{NO}_3)_2$, ammonia, soluble thiosulphates and sulphites (hyposulphites), in ferric chloride, in concentrated HCl , and as claimed by Mr. Brunton by the "base metal chlorides formed in roasting the ore".

Vogel gives the following table of solubilities of AgCl :

100 cc. saturated solution	BaCl_2	0.0143	gramme	AgCl
"	"	SnCl_2	0.0884	"
"	"	CaCl_2	0.0930	"
"	"	MgCl_2	0.1710	"
"	"	NaCl	0.0950	"
"	"	KCl	0.0472	"
"	"	NH_4Cl	0.1575	"

From these figures we see that MgCl_2 is nearly twice as strong a solvent as common salt, NaCl .

In the Augustin process the roasted ore was heated with a 5% solution of NaCl , the AgCl extracted with

hot saturated solution of NaCl, and the silver precipitated on copper. The Percy-Patera process improved the Augustin process by using the solvent power of sodium hyposulphite, instead of salt, and precipitated the silver with Na_2S , thus regenerating the hyposulphite. The Russell process made use of sodium thiosulphite and cupric sulphite, which it is claimed is a solvent of silver chloride, metallic gold, and silver as also the sulphide, arsenate, or antimony of silver.

It is to be hoped that others will join this discussion, because it opens a new field for those who have been unable to treat middling flotation concentrates.

Nayarit, Mexico, July 12.

ALGENON DEL MAR.

Stocks and Prices

The Editor:

Sir—Anent the 'Hints to Speculators and Investors in Mines', which appeared in your last issue, I am led to make the query of how many investors in this present day take without question the advice of such a market-letter as the last one of Hayden, Stone & Co. under date of July 22, wherein they say with reference to a substantial dividend-paying copper property, "It would seem fairly reasonable to count on a production of 75,000,000 lb. per year from this property, at a *profit*, with a full demand for copper, of at least six cents per pound".

This prediction, after just stating, in a preceding paragraph, that the estimated cost of production of this very same company—last year—was 12½c. per pound, and this one of the *lowest* cost that was reported.

I am inclined to think that the Cornish book, published in 1857, is still a good guide, especially the advice set forth in Section 13, rather than the average market-letter of an interested broker. While it is acknowledged that the future demand for copper will be very large, the wiseacres refrain from giving us even a guess as to the price of the metal at this time next year. More accuracy as to the surplus stock of the metal would be welcome.

San Francisco, July 29.

F. L. SIZER.

'Pyrites' and 'Pyrite'

The Editor:

Sir—I note a brief letter from Mr. Walter W. Bradley in your issue of August 6, together with an editorial note commenting on the distinction between these two words. The discussion raises some interesting points. Had Mr. Bradley not written the last paragraph, his letter would have been unimpeachable so far as his ideas of 'pyrite' and 'pyrites' are concerned. In the last paragraph, however, he reveals the fact that he considers 'pyrites' ('pie-rie-tees' presumably) to be the plural of 'pyrite'. If he had had 'pie-rights' in mind he would not have been so precise in his use of the terms in the preceding paragraphs of his letter.

You are quite correct in stating that pyritēs is not the plural of pyrite; but beyond that point I find myself unable to agree with you. I submit the following conten-

tions, which I have numbered for the convenience of anyone who may wish to set me right if I am wrong.

(1) You say "Modern mineralogy has accepted 'ite' as the usual terminal and pyrite has been introduced in compliance with the custom". The inference is that 'pyrite' is a modern substitute for an obsolete pyritēs. I cannot agree with this. Pyrite is the name of a distinct mineral, containing 53.4% sulphur and 46.6% iron; its chemical composition may be expressed by the symbol FeS_2 . It has characteristic physical properties; the word represents a definite substance, precisely as does the word 'gold', or the word 'calcite'. Pyritēs, on the other hand, is the name that may be applied to any one of a group of minerals, a number of which are named by Mr. Bradley. It is comparable with jelly; for example we have plum and apple and currant and raspberry varieties. Pyritēs is generally singular in number, but it may be plural; there is a mineral sometimes called copper pyritēs (singular) and one called arsenical pyritēs (singular); these are two of the many kinds of pyritēs (singular); or it would be permissible to say these are two of the many pyritēs (plural).

(2) You say that "It [pyrite] has the advantage that it gives a plural". I venture to say that 'pyrite' has no plural except in the sense that 'gold' or 'calcite' or 'iron' may have a plural. One might say (but probably would not) that the gold from Alaska, that from California, and that from the Rand made three different golds. Some similar statement is the only kind in which a plural of 'pyrite' can be used correctly.

(3) You say, "Yes, there are several kinds of pyrite . . . ; the others are copper pyrite, arsenical pyrite, etc." Again I demur. There is only one kind of 'pyrite' for there is only one 'pyrite'. To designate chalcopyrite as 'copper pyrite' would be exactly analogous to using the expression 'copper calcite' when malachite is meant. It is correct, however, to say 'copper pyritēs' for chalcopyrite, just as it is correct to say 'copper carbonate' for malachite; this last is correct but not precise, for the reason that azurite might be meant.

(4) 'Iron pyrite' is like 'lime calcite' or 'golden gold'. 'Iron pyritēs' is correct, but inaccurate; as Mr. Bradley points out, it may mean either pyrite or marcasite.

I have ventured to trespass upon your space in discussing at some length a rather trivial point because I know that you are an advocate of precision.

San Francisco, August 7.

MINERALOGIST.

THE graphite industry during 1919 was affected by the cautious readjustment in the business world that began after the War, by modification or repeal of wartime commercial regulations, and by the usual uncertainties preceding a presidential election, states a U. S. Geological Survey bulletin. Marked depression was the consequence. The total sales of domestic natural graphite were 7422 short tons, valued at \$778,857, a decrease of 43% in quantity and 49% in value from the sales in 1918; but the business done was nevertheless of larger value than in any year prior to 1916.

Distillation of Oil-Shale

By David E. Day

The major operations in a plant producing oil from shale are: (1) mining and crushing the shale, (2) treating the shale to recover the oil, and (3) refining the oil into marketable products. The first and last of these operations present no new features. Although the mining of oil-shale may not be directly comparable to any particular type of mining, the general field of mining engineering is so broad as to cover almost any special case. Thus, though it cannot be definitely stated that long-wall or open-cut, or stoping methods will be required for oil-shale mining in general, when the specific mining conditions have been determined for a particular shale mine, practice standardized in other mines will be found that will fit those conditions closely. The same is partly true of methods for refining the crude oil, which differs essentially in chemical composition from any natural 'crude'; and, accordingly, the products refined from it differ from ordinary petroleum products. This difference will necessitate some changes from the present refining methods, but these changes are unimportant. Petroleum technologists are practically unanimous in the opinion that the refining of shale oil offers no insurmountable difficulties.

There remains only the problem of producing the oil from the shale—a problem that does not present any serious difficulties, but one that at present retards the operations of those who believe that the time for oil-shale development has arrived. Except in isolated instances, the only commercial method of recovering oil from shale is by means of a carefully regulated heat treatment. Although the condition in which the oil-producing substance exists in shale is not definitely known, it is almost certain that it is an exceedingly complex hydrocarbon. This hydrocarbon may be composed of relatively unaltered organic matter deposited with the shale, it may be liquid oil retained in the pores of the shale, or it may be the inspissated remains of originally liquid oil. Whatever its origin, the hydrocarbon is exceedingly complex; it cannot readily be dissolved and extracted by solvents; it adheres too closely to the shale to permit mechanical separation. There remains only the method of vaporizing this hydrocarbon, and condensing the vapors formed. In all probability, the original hydrocarbon is so complex or so tightly bound in the shale pores that it will not distil without 'cracking'. This contention accounts for the residue of carbon in the shale, for the amount of fixed gases formed, and for the presence of such a large percentage of unsaturated hydrocarbons in the recovered oil. Assuming that this theory is correct, and that a 'cracking' distillation is the only method of recovering oil from shale, the problem resolves itself into the controlled-heat treatment of a fragmentary material.

Early in their connection with oil-shale problems, the engineers of the Day Co. decided that retorting offered a wide field for the application of technical skill and experience; they felt that many of the retorts designed were not sound from a mechanical point of view. It appeared that the only logical method of solving a problem of this sort was to establish the technical principles involved, so that the general type of apparatus required would be evident; a study should then be made of analogous industries, so that the apparatus used should conform with standard engineering practice.

By the principles of retorting shale for oil is meant those that are involved in producing oil as the main and most important product. By-products introduce separate factors, which necessitate separate discussion. In this article the oil-shale retort will be treated as a machine for producing oil, and oil alone. The factors governing the efficiency and economy, and oil-recovery of a retort, considered from the standpoint of the retort alone and ignoring the factors introduced by the type of shale or its preparation before retorting, are as follows:

(1) Factors affecting efficiency:

- (a) Thin shale layer.
- (b) Mechanical agitation.
- (c) Complete heat control.
- (d) Efficient application of heat.
- (e) Efficient furnace design.
- (f) Simple mechanism.
- (g) Large unit capacity.

(2) Factors affecting economy:

- (a) Continuous operation.
- (b) Minimum number of moving parts.
- (c) Maximum use of automatic machinery.
- (d) Minimum fuel requirements.
- (e) Accessibility of parts.
- (f) Mechanical strength and endurance.

(3) Factors affecting the quantity and grade of oil recovered:

- (a) Temperature control.
- (b) Even heat application.
- (c) Progressive heating.
- (d) Protection of vapors from abnormal temperatures.
- (e) Free passage of vapors.
- (f) Freedom from dust.

FACTORS AFFECTING EFFICIENCY

THIN LAYER OF SHALE. The necessity for a thin layer of shale in the retort is due to the insulating qualities of the spent shale. Because of its high porosity and carbon content, spent shale is one of the best of insulating materials. A thickness of ten inches of spent shale is equal in insulating qualities to a two-course wall of fire-

brick. If the shale layer heated is thick, that portion of the layer lying nearest to the heating surface will be distilled quickly and easily, but this spent layer will insulate effectively the portion of the shale lying farther from the heat, and will make distillation exceedingly slow and difficult. This explains one of the faults of the Pumpherson retort in its application to American shale. This retort is circular in cross-section, with a diameter of 22 in. at the top and 26 in. at the bottom, and is heated from the outside. The minimum shale layer is therefore 11 in. thick. Experiments showed that it was relatively easy to distil the oil from the four-inch zone nearest to the retort, but that the complete distillation of the material lying within this zone took nearly four times as long as was necessary for the material in the outer zone, and necessitated a correspondingly larger amount of heat. A thick shale layer also affects the quantity and grade of oil recovered, and will be discussed under that head.

MECHANICAL AGITATION.* The agitation of the material as it passes through the retort is important, both from the standpoint of heat efficiency and operating efficiency. It is obvious that a greater shale layer may be retorted with the same amount of heat and in the same time, provided that it is constantly stirred and agitated, than would be possible if it remained stationary. The effect of this agitation is to remove constantly the spent material and to substitute fresh in its place, thus avoiding the insulating effect of a stationary layer of spent material in contact with the zone of heating. Furthermore, most rich shales tend to coke in the retort unless they are subjected to constant agitation. In the retorts of the Scotch type, where no mechanical agitation is used, and gravity alone is relied upon to carry the shale through the retort, rich shales coke, and adhere to the sides of the retort; they clog the apparatus and cause expensive shut-downs and repairs. Mechanical agitation has a decided effect on the quantity and grade of oil recovered and will be discussed under that head.

COMPLETE HEAT CONTROL. The importance of complete heat control is so obvious as to require little discussion. If too little heat is applied the time of retorting will be increased, with a loss in retort efficiency. If too much heat is applied, some of the oil will be lost as permanent gas, and heat will be wasted, thus reducing both operating and heat efficiency.

CORRECT APPLICATIONS OF HEAT. Not only must the heat be under complete control but it must be correctly applied. To achieve high efficiency, shale should be heated progressively to higher and higher temperatures: the greatest heat should be applied at the discharging end of the retort, and should decrease gradually toward the charging end. Furthermore, heat should be applied so that each particle of shale receives the same heat treatment. Careful retort design is necessary to produce this result. Another question worthy of consideration is the

relation of the area of effective heating surface to the total surface of the retort and to the tonnage treated in one charge. Many of the retorts are inefficient because the effective heating surface is only a small percentage of the surface actually heated. This is particularly true of horizontal and cylindrical retorts, where heat is applied to the entire circumference of the retort, whereas the effective heating area is limited to a relatively small arc on the bottom.

CORRECT FURNACE DESIGN. Too little attention has been given to the furnace in which the retort is placed. This furnace should not only be designed to regulate and apply the heat as discussed under the last three headings but should also be designed with attention to the general principles of furnace efficiency.

SIMPLE MECHANISM. The simpler the mechanism, the lower the cost of installation and of upkeep and operation. Many retorts that produce good results in the laboratory are totally unfitted for commercial operations because of the complication of their mechanism. It must be remembered that a commercial shale plant must be capable of handling large tonnages continuously. Any retort in which the mechanism is complicated needs frequent repair; shut-downs and the resulting loss are inevitable. Moreover, the retort will be subjected to a temperature at which iron will not withstand great stresses, so that metal moving parts subjected to heat cannot be expected to withstand the severe operating conditions.

LARGE CAPACITY. In designing an oil-shale retort, or in considering the adoption of a process, the primary consideration should be the adaptability of the retort to large-scale operations. The oil-shale industry is fundamentally a low-grade mining enterprise. To be commercially successful it must handle large tonnages at low costs. For this reason any successful retort must not only be adaptable to large-scale development, but must be capable of attaining this development without too great a duplication of units. It has been emphasized before that the construction of a successful experimental shale-retort is not a difficult matter, but that duplicating the results on a large scale is another problem. It is not beyond the powers of a good engineer to grasp quickly the potentialities of a retort from this point of view, and it is surprising how often this fundamentally important factor is overlooked.

FACTORS AFFECTING ECONOMY

CONTINUOUS OPERATION. Continuous operation is essential, not only from a standpoint of efficiency but to secure economical operations. No matter how ideal a batch type of retort may be from an efficiency standpoint, it can never be as economical as a correctly designed continuous retort. The time required to empty and recharge a retort of the non-continuous type is a total loss; even if this period consumes only ten minutes of every hour, such a retort would be idle for 16⅔% of the time, or 50 days out of a 300-day working year. Heat is wasted during the idle period if the retort is kept hot, or an

*Agitation, in the sense used in this discussion, means slow irregular movement, both lateral and vertical, rather than violent motion.

excess of heat is required in starting if it is allowed to cool down. A non-continuous type of apparatus cannot be made as nearly automatic as a continuous retort, and consequently requires a greater labor and superintendence charge per ton capacity.

MINIMUM NUMBER OF MOVING PARTS. The number of moving parts required should be kept at a minimum not only for the reasons discussed under efficiency, but also

have defeated their own purpose by introducing an impossible amount of complicated machinery.

MINIMUM FUEL REQUIREMENTS. It is obvious that to obtain operating economy, fuel requirements should be kept at a minimum. For this reason full use should be made of all possible heat applied (1) by designing an efficient furnace, (2) by controlling the heat applied, and (3) by recovering some of the heat at least from the

Cross section thru center

Outside view showing assembly of cast iron retort proper

Outside view of vapor manifold assembly

THE DAY-HELLER OIL-SHALE RETORT
TYPE.- CONTINUOUS-VERTICAL-ROTARY
AS PRESENT APPLIED FOR -

for reasons of economy. In the first place, these parts require power to operate them, and this means expense. In the second place, moving parts are always subject to wear, and in course of time will need replacing. The relation of moving parts to high temperatures, as already discussed, is an important consideration.

MAXIMUM USE OF AUTOMATIC MACHINERY. The effect of automatic machinery on the economy of operation is too well known to require discussion. This factor has perhaps been over-emphasized by many inventors, who in their attempt to make an entirely automatic retort

spent shale and the vapors. It is, of course, impossible to recover all the heat applied during the operation, but it is unnecessary to waste it all. The heat in the spent shale may be used to pre-heat air for combustion or in the production of producer-gas; the heat in the vapors may be recovered to some extent, by the use of heat exchangers, in pre-heating the incoming shale. Very little thought has been given to this subject, which will have an important bearing on economical operations.

ACCESSIBILITY OF PARTS. The entire retort should be completely accessible. Shale may tend to coke or clog

the retort, or carbon may form on the walls. Consequently, access to the interior should be provided so that the walls may be scraped or cleared if necessary. The furnace should be so designed that damaged or burnt-out retorts may be replaced without tearing down the brick-work. Finally, if any dust is formed in the retort, it may be carried over by the vapors and deposited in the vapor lines. For this reason these lines should be arranged for easy cleaning.

MECHANICAL STRENGTH AND ENDURANCE. The last and, possibly, the most important factor is the mechanical strength and endurance of the retort. No matter how sound and perfect a retort may be from a theoretical point of view, it is worthless unless it can withstand continuous service without excessive repairs and replacements. To accomplish this result the parts subject to stress must be protected from heat, moving parts and complications must be reduced to a minimum, and the whole structure must be designed with a clear understanding of operating conditions and a knowledge of sound mechanical construction.

FACTORS AFFECTING THE QUANTITY AND GRADE OF OIL RECOVERED

TEMPERATURE CONTROL. If the theory that oil is produced from shale by 'cracking' complex hydrocarbons, already existing in the shale, is adopted, the importance of complete temperature control is at once evident. Experiments have proved that radically different results are obtained when shales are treated at different temperatures. When high temperatures are used a large amount of light oil is produced at the expense of a lessened total recovery. When low temperatures are used, a maximum amount of oil is recovered, but this oil has a small percentage of low boiling hydrocarbons. Market conditions will determine the product from which the greatest net return can be expected. To recover this product, the range of temperature necessary must be determined, and the retort must be operated constantly at these temperatures. Absolute temperature control is essential in accomplishing this result.

EVEN HEAT CONTROL. Inasmuch as the use of different temperatures will result in the production of different grades of oil from the same shale, similar heat treatment must be given to each particle of shale in order to produce an even product and to avoid losses. This will necessitate

- (1) A thin layer of shale.
- (2) Mechanical agitation.
- (3) Continuous treatment.

The thin layer of shale avoids over-heating of the shale nearest to the retort wall in the attempt to heat sufficiently the shale further removed. Mechanical agitation further reduces the effective insulating property of the shale layer, and makes even treatment of the individual particles possible. Uniform heating conditions can only be maintained by continuous treatment.

PROGRESSIVE HEATING. Experimental work and research have shown that to obtain a maximum yield of the

most desirable product, the shale must be heated progressively. In practice the temperature of the shale should be increased gradually to the point at which oil vapors are formed, and then increased uniformly until all the oil is driven off. To accomplish this not only necessitates perfect control of the heat applied, but also involves the application of the most intense heat at the discharging end of the retort, with an even decrease to the charging end.

PROTECTION OF VAPORS FROM ABNORMAL HEAT. Shale vapors as formed are composed of complex molecules which are easily dissociated if exposed to temperatures higher than those at which these vapors were formed. Some of this breaking down or 'cracking' may be desirable for the production of light oils, but in any case it must be carefully controlled. In general, it seems essential to withdraw the vapors as rapidly as formed, and to protect them from high temperatures. If, on the other hand, the vapors come in contact with a layer of relatively cool shale, and are condensed and re-vaporized, a large loss will result, and undesirable hydrocarbons will be produced. Except in special cases, therefore, the vapors should be withdrawn without over-heating or re-distillation.

FREE PASSAGE OF VAPORS. One of the most essential factors in obtaining the result discussed above is a free passage for the vapors, not only in the retort itself but also from the retort to the condenser. Pressure in the retort is probably undesirable from the standpoint of products formed, and it certainly increases the difficulty of preventing leaks, particularly in a continuous apparatus. The use of vacuum, on the other hand, although theoretically desirable, introduces mechanical complications that should be avoided if possible. The best plan is to provide passages for the vapors that are sufficiently large to allow them to pass out freely without creating pressure in the retort and without necessitating the use of vacuum.

FREEDOM FROM DUST. Although, as already discussed, mechanical agitation is essential to successful retorting, this agitation should not produce dust by grinding the shale, nor should it tend to stir up the dust that may be present with the crushed shale. Shale dust, if given the opportunity, will go over into the vapor lines and condenser with the vapors, and will absorb oil to form a thick paste, which not only clogs the lines and causes countless mechanical difficulties, but also wastes a large amount of oil.

THE RETORTING APPARATUS

The determination of the factors just discussed indicated certain features essential to the retorting apparatus. It is directly evident that the retort should be continuous, it should be capable of complete temperature control, it should agitate the shale, it should treat the shale in a thin layer, it should heat the shale progressively, it should avoid dust, it should be simple mechanically, it should be of large capacity, and it should be strong and durable. It also indicated that the retort should be vertical because of the mechanical difficulties

involved in externally heating a horizontal retort. In a vertical retort, the stresses all act downward on a firm basal support, whereas in the externally-heated horizontal retort, these stresses are balanced only at the points of support and the unbalanced stresses between these points cause the retort walls to sag and to twist out of shape.

Consequently, the study of apparatus used in other industries that may be applied to oil-shale work is limited to continuous and vertical furnaces that are capable of applying a carefully regulated heat to a fragmentary material. The industries that immediately suggest themselves as analogous are those connected with oil-shale operations in other countries, the by-product coking of coal, and the heat treatment of ores in roasting-furnaces.

ROASTING PRACTICE. The type of furnace developed for roasting ores is well adapted to the problems encountered in that industry, and presents good data on the mechanical methods of heating crushed material. Certain differences in the technical problems encountered prevents its adaptability to the retorting of oil-shale. The majority of such furnaces are direct fired; the hot gases act directly on the material to be treated. This results in a high heat-efficiency but also involves the use of a gaseous heat medium that will mingle with the vapors produced from the shale. If this heat medium is composed of ordinary furnace gases, a certain amount of un-reduced air will enter the retort and will oxidize a part of the oil. If this heat medium be an inactive gas, such as the fixed gas produced from the shale, a large volume of it must be used in comparison with the vapors formed; and the problem of condensing a fairly small amount of vapor from a large amount of permanent gas is a difficult one. Furthermore, roasting-furnaces of the multiple-hearth type require comparatively finely crushed material, and the dust produced as this falls from hearth to hearth will constitute a problem.

BY-PRODUCT COKING AND SCOTCH-SHALE PRACTICE. The shale industry in Scotland and the standard methods of by-product coking may be considered together, inasmuch as the coke-ovens were developed from the Scotch-shale retort. The retort generally used in both these industries is vertical, with a round or oval horizontal section. Coal or shale is fed at the top of the retort, passes through the heating zone, and is continuously removed at the bottom. Mechanically, this type of retort has been developed to a high state of perfection, but technically and economically it is open to objections. The most important defects are the thick layer of material treated and the lack of mechanical agitation. Furthermore, it has been found that rich shales will sometimes coke in a retort of this type, where no mechanical agitation is introduced. In experiments conducted with a Pumpherson retort at Autun, France, in the distillation of rich Australian shale, the coking effect was so serious that the apparatus was considered unsuited for the distillation of shales carrying more than 30 gallons to the ton. There appears to be little hope, then, of adapting Scotch prac-

tice, or coke-oven practice, to the American shale industry without important changes.

However, certain specialized apparatus used by the Germans in retorting brown coal seems to have a direct bearing on the problem. The Rolle retort, which is at present the most successful low-temperature apparatus for coal distillation, appeared to be particularly well adapted to oil-shale distillation. This retort consists of a vertical and cylindrical shell, to the exterior of which the heat is applied, and an internal structure of horizontal rings positioned concentrically in the retort, with their outer faces slanting downward. The space between the rings and the retort wall is filled with shale; the open space within the rings serves as a vapor passage. This retort is continuous and vertical. It treats the shale in a thin layer, and heats it progressively. It has no tendency to form dust, it is simple mechanically, and it has a large capacity. The only essential factors lacking are agitation of the shale and efficient temperature control.

The engineers in charge of this investigation for the Day Co. decided that this retort could be easily adapted to oil-shale retorting by introducing mechanical agitation and temperature control, and plans were immediately started to accomplish this step. The result is a retort which combines all the necessary technical factors, and is at the same time simple, strong, efficient, and of large capacity.

THE DAY-HELLER RETORT

The diagrammatic sketch shown herewith indicates (1) a cross-section of the complete assembly, with furnace and flues, (2) an outside view of the cast-iron retort proper, and (3) an outside view of the vapor-manifold assembly. It is seen that the retort is composed of three main parts: (1) the retort-shell, which may be made of cast-iron, cast-steel, or refractory material, (2) the vapor-manifold, and (3) the furnace.

RETORT-SHELL. The retort-shell is circular in horizontal section, and is composed of any number of units in baffled cross-section, as shown in the sketch. At the top, the retort is provided with a removable cover-plate, with an opening for admitting the untreated shale. At the bottom, there is a suitable shale-extractor and a double-walled chamber for pre-heating the air for combustion and for cooling the spent shale. This retort is vertical and stationary and is enclosed by a suitable furnace.

VAPOR-MANIFOLD. The vapor-manifold consists of a pipe upon which semi-conical baffles are mounted. Beneath the baffles are large perforations. This manifold is placed concentrically in the retort as shown in the drawing. At its upper end it engages a removable bearing brace, which connects the vapor-manifold to the condenser-line as shown. The lower end of the vapor-manifold protrudes through the bottom of the retort, with suitable seals for shale dust and vapors. On its lower extremity a removable bearing-lug is mounted, which, resting on a roller-bearing, takes the weight of the manifold, as well as the thrust exerted by the shale resting on the baffles. Above this bearing-lug is a split gear, by

which the entire vapor-manifold may be rotated. The position of the baffles on the vapor manifold with relation to the baffles formed by the walls of the retort is indicated in the drawing.

FURNACE. Surrounding the retort is a circular furnace, so arranged that a series of fire-tile forms annular flues with the indentations in the retort walls. Two diametrically opposed vertical flues permit the passage of the gases from one annular flue to the other, and also permit by-passing the heat to the point most needed.

OPERATION. In operation, shale is allowed to fill the space between the baffles on the vapor-manifold and those formed by the retort wall. The vapor-manifold is rotated slowly and constantly, and fresh shale is continuously added at the top as spent shale is removed from the bottom. Hot gases from any suitable type of fire-box are circulated in the annular flues, entering at the bottom, making a complete revolution around each flue, and leaving through the stack at the top of the furnace.

The shale enters continuously, and is spread in a thin layer over the baffles on the vapor-manifold and the retort wall. As it descends from baffle to baffle it is turned over and at the same time it is constantly agitated by the revolving vapor-manifold. The result is an even treatment of the individual shale particles, the prevention of caking, and exceedingly economical heating. The zig-zag form of retort walls produces a large heating area (nearly twice that of a cylindrical wall of the same proportion). Furthermore, these indentations in the retort walls form annular flues that can be maintained at any desired temperature, insuring perfect heat control. The vapors formed have only to reverse a very thin layer of shale before they reach the open spaces under the truncated cones on the moving manifold, and then pass through large perforations into the vapor-manifold proper, and out to the condensers. The baffles prevent shale particles from lodging in the perforations; for this reason these perforations may be made sufficiently large to permit easy passage of the vapors and to obviate clogging with dust. The vapors pass constantly into zones of temperature lower than that at which they were formed. As soon as they reach the vapor-manifold they are insulated from the furnace heat by the layer of shale surrounding them, and they then pass out through the top of the retort, giving some of their heat to the incoming shale, without coming into direct contact with it. At the base of the retort there is an air-jacket that cools the spent shale and pre-heats air for combustion.

Mechanically, the retort is extremely simple. There is only one moving part—the vapor-manifold—and this is strong and durable. It moves slowly, encounters no stresses acting directly against its motion, and is insulated from the heat. Access may be had to the complete retort by lifting the vapor-manifold out through the top. This can readily be done by unbolting the cover plate, by lifting the upper brace bearing from its lugs, and by removing the gear and bearing from the lower end of the manifold pipe. With the manifold removed, the retort is open for inspection and clearing. All the parts are

standardized, and are interchangeable with similar parts in other units, so that by keeping a few spare parts on hand a large plant may be operated continuously without serious shut-downs and delays.

The furnace is designed particularly for high efficiency, economy, and complete control. The greatest objection to a vertical furnace is the difficulty of efficient heating. This has been overcome in this retort by using horizontal annular flues, which are separate and independently controlled by dampers. The retort has a high capacity compared to its bulk and to the ground space occupied. Thus a single unit 25 ft. high and 10 ft. in diameter, including flues, will have a capacity of from 100 to 250 tons per 24 hours, depending on the type of shale treated.

SPEAKING of the question of man-efficiency at a discussion of the paper of A. E. Pettit on 'Notes and Records of Mining Costs', before the Institution of Mining & Metallurgy recently, R. E. Palmer showed that, on the Witwatersrand, in 1894 the production was 70 tons per man per annum. This went on increasing, until in 1902 it was 80 tons, or an increase of nearly 13%. In 1903 rock-drills were introduced, and it would be interesting to know whether they were introduced for the purpose of reducing the cost of production with cheap labor, or for the purpose of replacing labor unobtainable. As the working costs immediately began to decrease it might be presumed that the introduction of mechanical drills accounted for a portion at least. As might be expected, the man-efficiency rose in 1904 to 103 tons per annum; and, as more rock-drills were added, this continued to increase until it reached a maximum in 1914: 153 tons per man per annum. The fact remained, however, that the Rand engineers had been able to increase the man-efficiency from 103 tons in 1904—a year after the introduction of rock-drills—to 150 tons in 1917, when the number of rock-drills was at a maximum, or an increase of about 40%. The working costs dropped from 24s.4d. to 19s.2d. per ton during the same period. In the Rand they had one type of labor, in Great Britain another, in India another, in Spain another, and in Canada or the United States another, and in Australia another; it was not to be supposed that, given the same conditions, the output, without undue use of physical force, would be the same. Still it should not be a great difficulty to group them according to their capacity, and expect an equivalent output from the members of each group. By altering conditions on the Rand the man-tonnage had been increased by nearly 40%, from 80.7 in January 1920 to 117.3 in July of the same year.

THE increasing production of zinc skimmings, ashes, hard zinc, and scrap zinc, from which zinc is recovered in the form of metal, alloy, pigment, or chemical, and so used again, affects the consumption of primary zinc, states a U. S. Geological Survey bulletin. The total quantity of secondary zinc recovered in 1918 was 120,590 tons, as compared with 116,200 tons in 1917.

The Volatilization Process at the Pope-Shenon Mine

By Robert H. Bradford

The Pope-Shenon mine is situated eight miles south of Salmon, in Lemhi county, Idaho. Prior to 1917 the company had developed a large tonnage of oxidized copper ore; it was for the purpose of devising a method for treating this ore that I was called into consultation at that time.

The results of extended tests demonstrated the feasibility of using some method of leaching, for the ore contains only a little calcium carbonate or other acid-consuming mineral. However, the distance of the property from sources of supply of scrap-iron for precipitating copper from the acid solution presented a serious obstacle to leaching. To erect an electrolytic plant seemed, in the light of current practice, at the time these tests were made, a serious venture; moreover, no large permanent supply of electric power was available in the region, and, during the War, prices for ammonia and acids rose excessively.

Inspired by the results of testing already done on lead and copper ores at our metallurgical research laboratory in the University of Utah, and by the results of volatilization tests previously carried out by other experimenters, including Stuart Croasdale, Selden I. Clawson, and Ben Howe, I recommended to the Pope-Shenon company that it send to the University of Utah a sufficient quantity of its oxidized ore to enable the making of complete volatilization tests for the extraction of the copper. These tests were commenced in June 1918, the metallurgical research department of the University of Utah and the Intermountain Station of the U. S. Bureau of Mines co-operating in the work. My tests on small amounts of ore were highly successful; the smaller tests led to larger ones; the equipment was extended and the final volatilization tests were made in a rotary-kiln furnace 20 ft. long, with an inside diameter, for two-thirds its length, of 13 in., and for the remaining third, at the fire end, of 22 in. Several tons of Pope-Shenon ore was used in carrying out the tests with this rotary-kiln type of furnace.

We employed the Cottrell apparatus for precipitating the fume from most of these tests, but did some work with muslin bags as well. Both processes seemed more promising than any wet method of precipitation that other experimenters had employed. We finally confined our tests to the Cottrell process, which later was recommended to the Pope-Shenon company for its plant near Salmon.

The question of the reduction of the dry chloride fume

to metal was early before us. The results of reducing lead chloride to metal by fusing with lime and coke had not been encouraging, although we had confirmed the chemistry of the reaction involved and had tried the operation on a small scale. Now, with the larger quantities of nearly pure chlorides of copper we found the verification of the theory easy. The first fusion test performed on 200 grammes of Cottrell fume, containing 41% copper, gave a fluid-pour and we anxiously awaited the cooling of the mold in order to satisfy ourselves that the copper was at the bottom. Our hopes were more than realized when we took from the bottom of the mold a clean bar of copper weighing 78 gm., or over 90% of the weight of the copper in the fume. The metal from this fusion contained small amounts of sulphur and iron,

FURNACE FOR VOLATILIZATION

but was about 95% pure. Other fusion tests made with more carefully calculated charges gave higher extractions and better grades of copper. The fusion with lime and coke was checked thoroughly, and this method of reduction was recommended for the pioneer plant at the Pope-Shenon mine.

The slag was found to be principally calcium chloride carrying about 2% copper along with the silica and other impurities in the fume. Slag, analyzing 50% chlorine, was found to act vigorously in chloridizing the copper in a new lot of ore. This slag was even more active than raw calcium chloride, for the moisture, which makes up 25% or more of the raw material, was absent from the slag. It was recommended therefore that the company provide for the re-use of the fusion-furnace slag as a chloridizing agent in the volatilization furnace.

The one feature that we could not determine definitely by laboratory tests was the kind and size of furnace required for the reduction of fume to metal. We had not

produced copper-chloride fume in quantity sufficient to enable us to decide this point. Upon making inquiry of the manufacturer of one type of fusion furnace as to whether we could rely upon his furnace to do the work we received the reply that if we would send him a ton of fume he would experiment and let us know whether his furnace would do our work. We did not try to prepare a ton of fume in our laboratory tests, but decided to await the erection of the volatilization unit of the plant at Salmon. We did provide a small potless tilting-furnace to use for the fusion and reduction of the fume at the plant in order that we might determine the size of furnace necessary for the work. With this tilting-furnace we melted the fume from the Cottrell treater in lots up to 500 lb. with satisfactory results. The hearth-area for a given amount of fume per day was decided upon and a reverberatory furnace was designed to treat that amount of fume.

The laboratory tests on the larger lots of ore gave satisfactory results with the rotary-kiln furnace. A similar furnace, therefore, was decided upon; in fact, the important principle was kept in mind in the design of the entire plant, that no new and untried furnace or machine should be used. We did not wish to risk mechanical difficulties when we knew we would have metallurgical innovations 'a plenty' to attend to. Standard but up-to-date machinery and apparatus were chosen, and of the wisdom of this procedure we are now convinced.

The reduction plant as completed provides modern means for preparing the ore for treatment. The bin at the mine takes the ore from the mine-cars. A man below draws the gate and the ore slides into a surface tram-car to be lowered by gravity to the mill, 500 ft. down the hillside. Cars are lowered on a double-track tramway, where they dump automatically into the bin at the mill; the full car descending brings back the empty.

From the mill-bin a Wahlin feeder provides a uniform feed to a Universal high-speed jaw-crusher. The products from crusher and grizzly go to a bucket-elevator to be raised to a Mitchell vibrating screen. The cloth on the screen is 10-mesh; the undersize goes to the bin for crushed ore. The oversize drops to the rolls and its product goes back to the vibrating screen in closed circuit.

An inclined belt-conveyor transfers the fine ore to a cross-belt conveyor running over the bins. This last belt-conveyor is shifted by hand to feed the fine ore to the storage-bins, of which there are three in a row, each holding a day's run of ore; a bin for salt is alongside. Ore-chutes from beneath the four bins mentioned deliver the ore and the salt. The Wahlin pulley-feeders used are quickly adjusted to feed the exact quantity desired, so that with proper adjustment for ore and for chloride the computed mixture remains the same till the ore-bin is emptied. The feeders deliver the ore and the salt to a long belt-conveyor that in turn delivers the 'mix' to a distributing box arranged just above the steel hopper provided for holding two tons of the mixed ore and salt.

This hopper, with the shape of an inverted pyramid, has at its bottom a plunger-feeder above the furnace. The length and the number of strokes of this feeder determine the rate at which the mix is fed, and can be adjusted to suit conditions.

The cold ore drops through the steel chute from the plunger; it is raised by the revolving furnace until it drops back by gravity, slipping and sliding, heating as it moves slowly down the kiln. By the time the ore and the chloride are heated the mixing is thorough enough to provide the intimate contact required as a physical aid to volatilizing reactions between the salt and the metal. During the course of the ore through the furnace the volatile fume is escaping until the spent ore drops into the discharging launder freed from its copper, but granular still. Only incipient fusion commences and often the residue carries some dust. Unless too much salt in proportion to copper is added and free salt remains to make the tail pasty, a furnace sufficiently hot to ensure the volatilizing of the chlorides of copper is safely maintained without fear of fusion.

The launder that receives the spent ore carries the surplus water from a tank on the steep hillside. This tank, supplied by a spring, is also a protection against fire; 16,000 gallons of water is stored, with supply- and discharge-pipes attached underneath. The fire-line is a 2½-in. pipe, furnishing a stream that will protect the highest point of the mill structure. This provision reduces the fire-risk and the insurance rate.

The overflow-pipe from the tank on the hillside furnishes water to sluice the tailing through the discharging launder, constructed of concrete, with a slope of 1½ in. per foot. The water shoots from the pipe through a nozzle arranged to play on the stream of red-hot ore. With uniform streams of both water and tailing everything works smoothly, and the flow of the stream down the launder and over the hillside is uniform. If the furnace discharge is sintered and balled and furnishes lumps to be sprayed, regular progress is greatly impeded; and for this reason care must be taken properly to regulate the mixture and the temperature. The space available for dumping is enormous.

The fume from the furnace passes from the feed end into a flue for collecting; the dust is carried away mechanically from the ore-mixture by the moderately strong draught through the kiln.

The flue is made of reinforced concrete provided with hoppers to collect the dust. The coarser particles drop into the hopper next to the furnace, and in turn the smaller pieces accumulate in successive hoppers. The settling-chamber is 5 ft. by 4 ft. for the first 12 ft. of length; it is then increased in height from 4 ft. to 10 ft. The chloride fume, free from the furnace dust, goes to the Cottrell precipitator from the top and at the end of the chamber through a large fan with a slow-moving vane.

The treater is also of reinforced concrete; it has 36 pipes, each 15 ft. long and of 8-in. diameter, made of sheet-iron. These pipes are suspended from a concrete

header-floor hanging vertically through the floor at the top of the collecting-hopper, into which all the fume passes directly from the fan. The pipes extend downward through the bottom header for one-third of their length, so that the incoming fume passes between and around them. This serves to distribute the fume more uniformly to the open-mouthed pipes. Small iron wires pass down through these pipes, carefully centred from a grid at the top. Twenty-pound cast-iron weights keep the wires taut, and just above the weights another grid prevents swinging. Both of these grids and the sus-

every hour, or, at stated intervals, when the deposit builds to one inch thick, the hammers, operated by levers connected with ropes, are brought into action and the pipes are tapped. It takes but a moment to shake down the fume, but during this interval all draught is stopped and the stack-doors are closed. Since all the pipes are in a single compartment a loss of fume results when they are tapped. A duplicate unit to be built will make possible continued operation of both kilns during the tapping period by turning the dampers so as to pass all the fume through one treater. All solids will thus be reclaimed from the fume, and gas only will escape from the top of the stacks.

Once every shift the accumulated fume passes through a screw-feeder and a closed bucket-elevator to a storage-bin, holding some 20 tons. The fume from this bin is fed by pulley-feeder to a conveyor that passes beneath the storage-bin holding the limestone and coke which are fed on to it. The three ingredients, thoroughly mixed, are discharged into a pair of feed-hoppers above the hearth of the reverberatory furnace.

When the mix from the hoppers is fed to the furnace the surface is melted by reflected heat from the roof before the oil flame is allowed to impinge upon it. This method prevents the escape of fume carried mechanically up through the stack. The melting-temperature of copper-chloride fume ranges from 700° to 800°C. It takes but a few minutes to heat the surface

ended wires are carefully insulated from the ground to carry a current of 75,000 volts and provide a brush-discharge from wires to pipes. The roof of the treater is of reinforced concrete; the whole structure is accordingly fireproof. On top of the flat roof two stacks are provided, 2 ft. in diameter and 20 ft. high, made of $\frac{1}{2}$ -in. steel plate closely riveted. Trap-doors, hinged at the top of these two stacks, close when the pipes below are being tapped. Below the suspended pipes hoppers provide for the accumulation of collected fume up to a limit of 85 cu. ft. Two tons of fume may collect in these hoppers before it approaches the weight too closely.

As the gases pass up through the pipes the solid particles become electrified and are deposited, forming a layer inside of the pipe and around the fine wire. Once

of each new addition of mixture and melt the top layer, thus forming a blanket to shield the light fluffy fume from the strong draught. As fusion proceeds, the reactions between the lime, the fume, and the coke are completed. The final products are metallic copper and slag of calcium chloride, both somewhat impure.

The grade of the copper as well as that of the slag depends on the impurities in the fume. The limestone and coke are added in quantities only sufficient to reduce the fume. The slag and the copper are handled in the usual way; the temperature is sufficiently high to avoid all danger from freezing. The slag is collected for use as a chloride to add to fresh ore for the rotary kiln. The slag should be kept in a closed bin to prevent its taking up moisture and becoming wet. It is fed in dry condi-

tion to the crushing-mill and ground each day to the same fineness as the ore and salt; it is then followed by ore through the crushing-mill, thereby making certain that all of the slag is cleaned from the launders and belts. While dry, this peculiar slag does not stick in the crushing-mill, but left as a coating it robs air of its moisture and wets the belt-conveyors, screens, and machines; it is accordingly desirable to follow it with ore.

The limestone and coke are fed to the bin at the head of the mill; they are crushed to the requisite fineness and are sent by an extended belt-conveyor to their respective storage-bins. The regular crushing machinery thus serves to reduce the ore, salt, lime, coke, and the slag.

The milling department has a capacity of 200 tons in 24 hours. The rotary kiln and the Cottrell precipitator provide a capacity of but 50 tons. The ore and the slag for a full day's furnace run are crushed in one shift in the milling department. Space has been left for an additional kiln of three times the capacity of the unit now running.

The Mineral Industry During 1920

By G. F. Loughlin

*The metal-mining industry continued far below normal during 1920, although there were some temporary improvements compared with 1919. Gold mining continued in a greatly depressed condition, and the value of the country's output decreased to less than \$50,000,000. Production decreased in all Western States except Arizona, where gold is obtained partly as a by-product of copper and lead ores, the output of both of which increased in that State in 1920. Less than half the gold mines of the country were active, and some large mines were closed permanently. Placer mining also was curtailed, not only because of excessive cost of operation, but because of shortage of water and hydro-electric power in California and Oregon and of local mishaps in certain other States. The small domestic production of platinum and allied metals, largely a by-product of placer gold mining, increased; the total production of refined platinum decreased. Other metals in the group showed small to moderate increases.

The production of silver was favored during the first five months of the year by a strong foreign demand and high prices, and, later, by the Pittman Act, which guaranteed a price of nearly \$1 per ounce to producers of new domestic silver after the price of silver from other sources had declined to pre-war levels. The output about equaled that of 1919, although the value declined 10%, owing to a drop of 10.5c. per ounce in the average price for the year. Miners of silver ore were especially favored, and a few mines that had been idle since the demonetization of silver were re-opened. The price of silver also aided in maintaining the production of ores of lead until late in the year, when the prices of all these metals declined to extremely low levels. Up to the end of 1920 the Government had purchased about

30,000,000 of the 208,000,000 oz. authorized by the Pittman Act. Total purchases up to May 27, 1921, amounted to 56,283,697 ounces.

The total production of copper decreased in 1920, although production in two of the leading Western States increased. Disposal of surplus stocks by some smelters early in the year and premature expectation of revived foreign trade encouraged large production. The apparent domestic consumption increased slightly, but less than had been expected, whereas the large total stocks decreased by only 30,000,000 lb., and foreign markets were still oversupplied with new and old copper. The resulting poor demand, especially during the latter half of the year, together with labor troubles, high operating costs, and the low rates of foreign exchange, caused a great curtailment of production during the last three months of the year. There was no immediate hope of recovery in the demand for copper, and by May 1921 most of the mines had been closed. The average price of copper for 1920 was about the same as for 1919, but by the end of 1920 quoted prices had reached pre-war levels.

Lead increased in output in 1920, but did not equal the output of 1918. The recoverable zinc content of ores mined in 1920 was also greater than that in 1919, though less than that in 1918. The smelter production of primary zinc from domestic ores, however, was a little less in 1920 than in 1919. Both lead and zinc were favored by higher average prices in 1920 than in 1919, but their prices declined rapidly toward the end of the year, when imports, favored by the low rates of foreign exchange, increased considerably. The low prices of lead and zinc at the end of 1920 caused great curtailment in production, and the output during the first four months of 1921 has probably been 50% of normal.

The increased demand for iron and steel during the first half of 1920 caused a corresponding demand for manganese, and both domestic production and imports increased markedly. Continued high prices and depleted reserves favored those best equipped to produce domestic manganese. In contrast to manganese, tungsten was in little demand, and domestic production was the smallest since 1920; nevertheless imports were large for peace times, in anticipation of a heavy duty. The production of domestic chromite, also affected by large stocks and by inability to compete with imports under normal conditions, underwent a further decrease. Only one molybdenum mine was operated during the year. The production of nickel in Canada underwent fluctuations similar to those in copper and iron. The production of titanium ore (rutile) more than doubled in quantity, and uranium and vanadium minerals, used to some extent in the steel industry but chiefly valuable because of their radium content, more than doubled in value. The production of bauxite for all uses increased nearly 40% in quantity and nearly 50% in value, and the value of aluminum manufactured also increased. Imports of aluminum also made a large increase. Continued growth of the aluminum industry in 1921, or as soon as industry revives, is expected.

Management of Mexican Labor

By Alonzo Crittenden

The general principles of human nature are about the same in every country and among all races, but native instincts should be taken into account in dealing with different nationalities. Successful management must be based on the principles of justice; but in order to do real justice, one must have the qualities of judgment, courage, experience, as well as an intelligent knowledge of conditions. Mexican servants have been called the best and the worst in the world, and the same may be said of Mexican unskilled labor.

Colonel Kosterlitsky, the chief of the northern *rurales* of Mexico, was sitting in a *café* at Cananea. It was evening. An American friend had just asked him his opinion of the Mexican as a soldier. At that moment, the motor train from the smelter had dumped a load of liquid slag, and its fiery glow had lit up the surrounding landscape for a brief moment; then it faded into inky blackness. The Colonel pointed to the fiery molten mass: "You can lead the Mexicans through that," he said, "but they have no initiative—they can do nothing alone." This remark may be said to epitomize the handling of Mexican labor.

To understand the Mexican workman—and without understanding there can be no real success in directing him—one must go back to his racial origin. Half the population of Mexico is pure Indian. Of the remainder, about three-fifths is of mixed Spanish and Indian blood; and the rest Spanish, or other white stock, mostly Spanish. Those of Spanish descent are generally the dominant element, though there are numerous exceptions. Many of mixed blood hold influential positions; some of the great leaders have been Indian. Juarez was of pure Indian blood and Porfirio Diaz himself was one-quarter Indian. But the mass of the people, and nearly all the laboring class, show general Indian characteristics. Personal leadership is the main thing with them. They are guided by men, not issues.

Great things have been accomplished with this labor by those who understand and can direct it. Napoleon's maxim that an army of sheep led by a lion is better than an army of lions led by a sheep, although, like all epigrams, not embracing the whole truth, holds good. The Mexican workman intellectually is a child. He is governed by emotion rather than by reason. He does not bother to think about what does not immediately affect him. As a rule he is not hard to please and to satisfy; indeed, he is somewhat of a philosopher in a superficial way. He even has a strong feeling of loyalty to a boss who appeals to him as being the real thing, that is, whom he can respect and look up to. Such a one may be a hard boss, if he is a just one; mere driving and brutality, however, will not get one very far.

A Mexican, unlike a white workman, does not fear

being discharged. The idea of holding his job, and dreading the loss of it, will often cause a white man to accept much injustice, to work under unhealthy conditions and with excessive exertion for a considerable time; he wants to make good; he values public opinion and looks to the future. These motives do not act, to the same extent, as an incentive to the Mexican; frequently, they are unknown to him. One might say that there is no public opinion in Mexico; the Mexican workman does not think far enough ahead to bother about the future, and so he is mostly guided by his present emotions. Also, his personal likes and dislikes are strong; he readily responds to personal leadership, without thinking of the principles involved. It is inconceivable that he would fight through a war for a principle—an idea—as the American colonists did when they fought against taxation without representation. Yet he will fight well under the right kind of leadership. Some Mexicans who went to France in the Great War made good records.

Owing to the low intelligence, culture, and education of the laboring classes, caste lines are drawn strictly in Mexico; under existing conditions it is necessary to observe them if one is to be successful in directing and controlling Mexican labor. The Mexican workman will misunderstand an attitude of social equality toward him, and one adopting that attitude will be held in contempt; he cannot be your equal; he must either be your superior or your inferior. Treat him justly and kindly, but never with familiarity, for if you do you will not only lose his respect, but you will spoil him as a workman. He will regard this treatment as an evidence of weakness and fear, and will endeavor to become your master. In his eyes your attitude will be a confession of weakness and inferiority.

Many Americans, with the best of motives and the worst of judgment, have made this mistake and suffered for it. Many American mining men have been murdered by their *mozos* in the lonely mountains of the Sierra Madre. Yet many more have penetrated to the most wild and desolate parts of that region, alone, with ordinary Mexican *mozos* and with perfect security. I spent a year and a half in the most inaccessible parts of the Sierra Madre with Mexican and Indian *mozos*, and was treated with the utmost loyalty and respect.

One who travels much in Mexico will often hear the phrase, "It is the custom here", when he objects. They seem to think that it is an entirely sufficient reason to give in answer to any kick. I had often received this answer myself, and so, on the theory that "what was sauce for the goose, was sauce for the gander", I thought that I would try it on them when they objected to any of my rules or methods, although I must say, without a

great deal of confidence. However, it worked like a charm; the magic words seemed to satisfy completely my Mexican employees, and they would go off contented. It has been said of the Mexicans that a smile and a cigarette will go further with them than a substantial raise in wages, if accompanied with sourness. This is more or less true of any people. A smiling face and a pleasant manner are business assets.

The Mexicans are human, and, in common with all races, appreciate just treatment, although at the time they may not seem to show it. They resent injustice although they may not know how to remove the grievance and secure redress. In showing this resentment they often do not take the direct and straightforward course of protesting to their boss, or *patron*, against the injustice, and giving their reasons. They fail to adopt this obvious and manly way of endeavoring to secure redress, perhaps through timidity and fear of being placed at a disadvantage; but they will go the more crooked route of waiting for a favorable opportunity to strike on some mere pretext, which would not have been taken seriously by them had not the seeds of discontent and rancor been sown by continued acts of injustice.

At a mine in Sinaloa, the American superintendent had a system of petty impositions, which he practised on the men, and actually thought that he was serving his employers, the company, thereby. The traditional duration for work in the mine was ten hours per day, but he not only exacted the full time under the unwholesome and arduous conditions of modern mining, but even increased the actual time of their labor in different ways, by making them carry their tools a considerable distance on their own time. He also adopted a hard and unsympathetic attitude in all his relations toward them. This was an extremely unwise policy; before long the morale of the camp was spoiled; the men became indifferent, dissatisfied, and resentful; they showed their ill feeling in a number of ways. The superintendent was always having petty strikes to settle, and the working efficiency was low. The assistant superintendent was in charge when the superintendent was away on the company's business; and, adopting a more just and humane attitude toward the men, he was shown greater respect and exercised a greater control over the Mexicans. More work was done and a higher efficiency resulted. He also had a contented force. The Mexicans showed in many ways their resentment of the treatment accorded them in the one case, and their appreciation of their treatment in the other case. They favored the superintendent with a passive resistance and obstinacy that developed at times into active hostility; they would do nothing for him unless they were paid for it. If a crowd of Mexicans was close to where he dismounted, none would step forward to hold his horse. For the assistant, however, they rendered eager and willing service, and accorded him the respect and consideration that the Mexican workman is pleased to give if he thinks his master is worthy of it. This is something that money cannot buy. Money and authority can enforce an outward and superficial obedi-

ence, but there are things that neither authority nor force can compel, even from a Mexican laborer, though they are freely rendered to one who possesses higher traits of character. They were rendered to the assistant at this particular mine. If there were any Mexicans standing about where he dismounted, one or more instantly stepped forward to hold his horse; in many other small ways they showed their appreciation.

One of the most serious problems in that country is to keep *tequila* and *mezcal* (the native whiskey) away from the Mexican workmen; for when they are full of *mezcal* they are difficult to control. One day the superintendent and his assistants were working in the office. In a nearby shanty a crowd of Mexicans, men and women, were holding a celebration. It was immediately after pay-day and they had a brass band. They had smuggled plenty of *mezcal* and were having a hilarious time, much to the discomfort of those who had been on night-shift and were trying to sleep, and also to two officers of the company who were trying to work in the office. Situations such as this should be avoided by taking proper precautions, but if they do occur they should be handled with great discretion. In this case the 'super' lost his head. Aggravated beyond endurance he buckled on his pistol and remarked that he was going out to stop the nuisance. The assistant was unarmed but said he would go with him, so they both walked over to the scene of festivity. The 'super' ordered that the proceedings stop instantly, and told the musicians to leave the camp. A tall miner instantly stepped forward and told him that it was none of his business. One word led to another; the miner, who was too full of *mezcal* to be afraid of a gun, drew a knife and started for the Americans. The 'super' drew his gun and covered him. The other Mexicans were uncertain as to whom to follow. It was then that the assistant, who had hitherto been a silent witness of the scene, stepped forward and said sharply to the bystanders, "That man is drunk and will get himself into trouble. Seize him and hold him." The Mexicans, who respected him personally and were accustomed to obey his orders, leaped on the belligerent miner and pinned his arms. The assistant having thus assumed the leadership spoke a few words to the musicians in a cool and matter-of-fact way, and told them to disperse; the incident was closed.

In another case the company was driving a drift at the low cost of \$3.90 per foot in fairly hard rock. The Americans in charge pointed the holes and paid the Mexican miners so much per foot for doing the drilling—a system of piece-work. The miners were continually asking for a contract; they were making more than the usual wages by piece-work under the direction of the American boss, but they thought they could do better. At first they wanted \$10 per foot, but on being told that it was actually costing the company less than \$4, they finally consented to take the contract at \$4 per foot. Without the necessary supervision in pointing the holes, they soon began to run behind; they commenced to quarrel among themselves and made little progress. At the end of two

weeks they were in debt to the store, and were willing to give up their contract and go back to wages or piece-work. They had to have someone to do their thinking for them; they could do the work, but they could not plan it.

Good results have been accomplished with Mexican labor, and also dismal failures. The Anglo-Saxon laborer will maintain his standard of work under poor leadership, but the Mexican rapidly deteriorates. Real leadership implies a superiority—superiority in patience, knowledge, courtesy, tact, refinement, force, and courage. Character is the grandest thing, it is the basis of all achievement. Different types of men are successful in controlling Mexican labor, but whatever the type, it must be genuine. Any false note will have a bad effect on discipline. They respect the quiet and refined type of superior who has the air and manner of a gentleman and who possesses a confident way of directing them.

The boss should realize that his position is assured and that nothing that the Mexicans can do can affect him in the least. This will produce an attitude the reverse of arrogant, which generally springs from a lack of true worth and which it seeks to hide by a vulgar display of bluster. The supremacy of this type of boss is more marked than in the case of the mere driver, because his influence is a moral rather than a physical one. The mere driver, who rules only by force, may accomplish results with Mexican labor, but his success is not nearly so great or enduring. Firmness is necessary, but brutality defeats its own end. It has often been said that Diaz ruled Mexico with an iron hand, but that there was a great deal more to his rule than force alone. He was *simpatico*; this word has no equivalent in English; its use infers the highest praise that a Mexican can bestow to express liking and respect. It refers to one who is amiable and sympathetic in his personality and whose attitude is not inconsistent with an iron firmness when the need arises.

In dealing with Mexicans, it is as well to call their attention to every dereliction of duty; but not to censure them severely or to "hawl them out". The idea is to let them know that they are not 'getting by' or imposing on you. One should be perfectly calm and good-natured about it, yet serious. The employer of labor in an isolated camp must often be a judge, police officer, and general referee, as well as the director of operations. He should understand the Mexican's point of view and have the ability to sense the state of mind of his workers.

For a boss that they like and respect, the Mexicans have a great deal of loyalty. Some are steady workers, but many will slacken after a while and need to be discharged. A Mexican does not mind being discharged; he does not look upon it as an ignominy or a disgrace, as a white man does. If he gets too lazy and indifferent about his work, or especially if he gets to be a sore-head and complains or 'knoeks' to the other men, it is best to discharge him at once—the sooner the better—as his example will have a bad effect on the rest of the men. But this discharge need not be permanent. His malady is

generally acute, not chronic, and he will be cured in a little while. When he comes back and asks for work, as he almost invariably will, he should be re-engaged, and will probably make a good worker.

ANTIMONY is found over widely scattered areas in the central and southern Provinces of China, according to the U. S. Geological Survey, but principally in Hunan, Yunnan, Kweichow, and Kwangsi. The deposits have been developed for the last two decades. Those in Hunan have been most extensively exploited, probably 90% of the total production of China coming from the region about Changsha, the centre of the smelting industry. The most productive district in Hunan is Kai-keng-shan (Shikung-shan), in the valley of Tzu river, about 12 miles east of the Hsinhan. In 1915 about 70 companies mined antimony along the outcrop of the deposits in this district. The ore, which is mainly stibnite of remarkable purity, occurs as pockets and bunches in a flat bed of dolomitic limestone. Mining is carried on in a crude fashion by natives. Several local smelters produce liquated sulphide, and the output of the district in 1915 was about 1000 tons monthly of crude ore averaging about 70% metallic antimony. All regulus manufacture is controlled by the Wah Chang Co. The Panshi district, which produces considerably less, is 25 miles from Changsha, on Tzu river, in a very mountainous region. The ore in this district occurs in a series of veins in upturned slates, shales, and quartzites. The output of the district in 1915 consisted of about 400 tons monthly of 30% ore, all of which was shipped to the Wah Chang Co., at Changsha, for treatment. Other producing districts in Hunan are the Wa-shi district, east of Shenchowfu; the Hua-pan-hsi district, in Anhwa; and the Chiang-hsi-lung district, in Chupu-hsien. The only district in Yunnan where antimony is handled commercially is near Chih-tsun, on the Tongking-Yunnan railroad above Mengtse. The Pao Hua Co., connected with the Wah Chang Co., owns a French-constructed plant here and produces high-grade regulus. During the period of war-time high prices some antimony was smelted and refined at various points in the Provinces of Kwangtung and Kwangsi, but the smelters in these Provinces have now closed and the production has ceased. The Wah Chang Mining & Smelting Co. largely controls the production of antimony ore, regulus, and crude in the Province of Hunan. This company operates smelters in Changsha and owns certain mines of low-grade ore. It possesses a complete monopoly, granted by the Peking government, for the manufacture of regulus in Hunan, and owns the patent rights in China for the Herreschmidt furnace, the most successful means of reducing low-grade antimony ores. Most of the mines themselves are owned by natives and operated in a small way. In recent years there has been a tendency to smelt the ore at the mines, a procedure which promises to lower the cost of production. Adverse exchange conditions, due to the high price of silver, have nearly doubled the cost of production in China. Wages also have advanced in that country.

Fatigue, and Atmospheric Conditions in Mines

*Recent investigators have discussed the question of the health of underground workers, and have emphasized the necessity for conditions that will not lower the efficiency of the defensive mechanism of the human frame against disease. Although not directly conducive to specific diseases, such as miners' phthisis or tuberculosis, such conditions may result in a feebleness against them, and should therefore be avoided. In recent years there have been two remarkable changes in the opinion of competent authorities on the question of the relation of atmospheric conditions in mines to health. About twenty years ago it was thought that carbon dioxide was in itself a poisonous constituent in mine gases, and that the amount present should be kept below 1%. When the Transvaal Mining Regulations Commission of 1908 made its report, there was a change in this opinion; the Commission reported in favor of the present South African legal standard of 0.20% because it was considered that the amount of dioxide present was a rough indication of the amount of monoxide present; by reducing the former, the amount of the poisonous monoxide would be kept within safe limits. Within recent years further research has shown that much larger amounts than 0.20% of carbon dioxide are not injurious to the human system. I would, however, deprecate the advocacy of a ventilation system that would result in an atmosphere which has already been largely affected by the respiration of other persons, even although it might be otherwise unobjectionable in its freedom from dust or traces of irritant and poisonous gases. Although, according to Leonard Hill, an atmosphere containing large quantities of carbon dioxide, and heavily contaminated with the expired air of other persons, had no ill effects on students, it should be pointed out that an experiment of this character only shows the result of inhaling such air for a short period. If the test had been continued for a year the result might have been different. Coal miners in Great Britain and elsewhere enjoy good health, although the amount of carbon dioxide in the air they breathe is, in many cases, high. But the coal miner has the benefit of breathing air that has suffered little, if any, contamination from the breath of other persons. I see a source of danger in the suggestion that, so long as the air is moving, it does not matter much whether it contains 0.2 or, say, 1% of carbon dioxide. By all means keep the air moving, whatever its quality, but let us do our best at the same time to see that it is fresh.

There is, moreover, an added danger in using air over and over again—merely circulating it to give more comfort and to cause less fatigue to the worker. During such circulation the coarser particles of the dust, which such air may have picked up elsewhere, are eliminated, mostly

by settlement on adjacent surfaces; but the finer dust may go on accumulating. This fine dust is invisible, and no suspicion may arise that the air is not good. In one of the Geduld shafts some years ago it was found that, owing to a leakage in the pipes, a fan was circulating the air over and over again. This air was perfectly clear, but was found to show fine dust of about one micron diameter in numbers of 1000 and upward per cubic centimetre.

The other question on which medical opinion has lately undergone considerable change is the effect of high temperature and humidity on health. Only a few years ago it was generally considered that, although a wet-bulb temperature of 83°F. or over might greatly diminish a laborer's output of work, it had no detrimental effect on his health. Some of us had a suspicion that this was doubtful, but we did not venture to dispute it. Experiments with air in motion, and, more recently, statistics obtained from the use of the katathermometer, have thrown new light on the subject: the conclusion that conditions which induce undue fatigue when performing work must be detrimental to health is realized to be logical.

In the Final Report of the Miners' Phthisis Prevention Committee may be found statistics relating to death-rate and temperature, and referring to the year 1915-1916.

Underground Air Temperature (Dry Bulb) and Death-Rate in Rand Mines

Range of temperature	Number of mines in each temperature group	Total death rate in mines of each group	Pneumonia death rate	Total death rate excluding pneumonia
66°-68° F.	2	13.1	5.1	8.0
69°-71° F.	14	15.7	6.9	8.8
72°-74° F.	20	16.4	7.6	8.8
75°-77° F.	9	17.9	6.5	11.4
78°-80° F.	8	20.5	8.5	12.0

The Committee was in doubt whether the higher death-rate in the hotter mines, as shown in this table, was due entirely or mainly to the higher temperature, and comments as follows: "It may be pointed out that the hotter mines are also the deeper, and that the air in these mines differs from that of the shallower mines in other respects than temperature, as, for example, in barometric pressure. This may also affect the death-rate."

The higher temperature may be the main cause of the higher death-rate, in that it lessens, in various ways, the resistance of the body against disease. Further experimental work is needed to show the relative outputs at high temperature under varying conditions in respect of Kata readings and humidity. There is no doubt that if the conditions at higher temperatures can be ameliorated by ventilation and other means, the laborer will be able to show a fair output of work; but I am tempted to think that an additional but probably more effective method of increasing his working capacity is to employ him as little as possible on classes of labor that need a large output of energy. Substitute for the muscle of the laborer the energy of the compressor and the dynamo, directed by the brain of the worker, but involving as little muscular labor as possible, and it will probably be found that improved economy of exploitation and better health for the workman will result.

*A contribution, by Sir Robert Kotzé, to the discussion of a paper on the subject in a recent issue of the 'Journal' of the South African Institution of Engineers.

REVIEW OF MINING

THE WORLD'S ZINC INDUSTRY

The condition of the English zinc industry, according to the American Zinc Institute, is without change; British smelters cannot produce zinc at present market price. In the past it has been customary for all virgin zinc to be classified as g.o.b. (good ordinary brands), with the result that metal of 99% purity failed to command the premium to which it was entitled, except from those consumers who had found it necessary to restrict their dealings to certain brands which possessed characteristics suitable for the purposes intended. Thus the roller of sheets was satisfied to pay a premium varying from 2s.6d. to 10s. per ton for slab zinc containing a minimum of cadmium. There is no reason why the grades of higher purity zinc should not carry the same 'spread' as in America. In view of the fact that all the zinc which the British Board of Trade will receive under its long-term purchase agreement with Australia will be of a purity of 99.95%, one would think that they would enter upon an educative campaign among all consumers in the country for the purpose of satisfying various users that in many cases it is economical to pay premiums for specific qualities.

In France the zinc industry is not prospering, and there is no object in output being increased even at the re-built smelters at Montagne-du-Nord. In any case, France is never likely to aim at a production in excess of her own domestic requirements.

The Federation of Zinc Smelters in Belgium is maintaining its production at about 4500 tons per month, and a welcome revival in Continental consumption has prevented any marked augmentation of stocks. Slab zinc on hand in Belgium amounts to about 11,000 tons, but stocks of rolled-zinc sheets still remain at over 40,000 tons, mainly the property of the Vieille Montagne. The demand for ore is exceedingly light, for the reason that the Belgian smelters have sufficient calamine and blende on hand to carry them along until February 1922 at the present rate of zinc production. The smelters have still to take delivery of a considerable quantity of Australian concentrates under contract, and the treatment of these at the price paid represents a substantial loss at the current market price of the metal. Today, under existing circumstances, Belgium can hardly afford to pay more than £4 15s. per ton for Broken Hill concentrate of the standard grade of 47% zinc, 6% lead, and 10 oz. silver.

Notwithstanding the obscurity of the German zinc situation, two factors stand out clearly: (1) the current production is very light, and (2) the unsold stocks are not excessive. The total production today does not exceed 4000 tons per month, as smelting in Silesia is paralyzed, pending a definite decision on the fate of Upper Silesia. The Inter-Allied Commission has found that the settlement of this question bristles with difficulties. Zinc, in common with all manufactured goods in the disputed area, is to all intents and purposes immobilized for the time being. Owners of merchandise there can only offer on the promise of delivery when transportation from Upper Silesia is resumed. In Germany the consumption of zinc is small and the low production is sufficient to take care of it. The unsold stocks of

virgin zinc in the country are computed to be 16,000 tons, and the holders show no desire to offer this on the London market; indeed, the German government has hinted to the owners that the export of this comparatively small stock of zinc is undesirable. The British government has reduced the tax under the Reparations Act on German goods entering the United Kingdom from 50% to 26%, but in order to remove this disability to German exporters the German government has agreed to bear such burden itself. The *modus operandi* is for the German seller to accept payment of 74% of his invoice, the British buyer paying the remaining 26% to the British Customs as tax. Against the production of this British official receipt for 26% of each invoice the German seller is entitled to recover promptly from the German government the equivalent amount in marks at the exchange of the day on which payment of the 74% was made. Were Germany, however, a seller of zinc today, there is nothing to prevent her selling to a neutral country for re-sale to Great Britain, as German zinc so dealt in escapes the terms of the Reparation Act. This is a fact known to few, if any, of the English importers of continental metals.

In both Norway and Sweden the zinc smelters are operating at low capacity, which may be easily understood when it is explained that the producing cost at the hydrothermic works are certainly not less than the Belgium distillation works' cost today of £30. While Scandinavia outputs some 98.5% zinc, the main quantity runs from 99% to 99.9%. Generally speaking, European trade has been in such a condition during the past nine months that zinc of higher purity than prime Western has been difficult to place, except in small quantities; hence, it has been no uncommon occurrence for the Norwegian and Swedish sellers of late to deliver 99% purity metal against g.o.b. sales on the London market.

Both the distillation works in South Australia and the hydro-electrolytic works in Tasmania remain closed and operations are confined to the erection of further units at the latter point. The shipment of small parcels of zinc and zinc sheets from Europe to Australia during the past few weeks is recorded.

It is a source of satisfaction to other producing countries that the American zinc smelters are wisely limiting their output to the monthly consumption of 18,000 tons. With unsold stocks equal to five months' consumption at present rate, there should be no anxiety to lift production until a better trade demand develops.

INTERNATIONAL NICKEL

Instead of waiting for business to improve, International Nickel has devised a new method which is expected eventually to be a good revenue producer, states the 'Boston Financial News'. A new rolling-mill is being erected by the company to fabricate nickel, and it is hoped to have this in operation before the end of this year. The plight of the industry, however, is vividly portrayed in the quarterly statement of the company for the first quarter of its fiscal year ended June 30 last, profits after preferred dividends amounting to but two cents per share on the common stock. Small as the result is, however, it does not come as any

surprise to those who follow the industry. As a matter of fact, it was expected that the first quarter of the company's year would show a deficit after preferred dividends, so that the two cents per share on the junior issue may be considered satisfactory in view of the present situation. One of the very prominent reasons for the company showing a slight profit was due to the fact that early in March a reduction in wages amounting to 15% was put into effect. In addition, rigid economy in all departments helped in making it possible for the small quarterly profit of approximately \$46,000. Despite the poor start on the current year, the outlook is not so black as in other lines. One of the first industries to feel the effect of the readjustment, International Nickel is about ready to start forward again. Nickel stocks in consumers' hands are reported to be down to a minimum amount, and although the demand is still small a steady improvement is going on. While junior stockholders are not receiving any dividends, there is some consolation in the fact that the company is not losing money. In the year ended March 31, 1921, the company carried to surplus \$1,494,000, equivalent to 89c. per share on the outstanding common stock of \$25 par value. Although the resumption of dividends is still problematical, when normal conditions develop the company should be in a position to resume.

SILVER AND GOLD PRODUCTION IN MEXICO

The following tables, from official sources, gives data as to the silver and gold produced in Mexico for the first six months of 1920 and 1921, respectively.

Production of Silver

	1920 Oz.	1921 Oz.
January	5,301,599	7,206,060
February	5,646,591	5,661,358
March	5,891,070	3,815,176
April	5,081,275	4,846,741
May	5,337,414	3,894,841
June	5,851,718	5,075,328
Total	33,112,667	30,499,504

Production of Gold

	1920 Oz.	1921 Oz.
January	60,667	69,380
February	64,846	57,709
March	64,975	51,597
April	60,543	45,235
May	65,041	54,761
June	73,913	41,797
Total	379,985	320,579

Value of Silver and Gold Produced, Six Months Period

	1920	1921
Silver	\$77,483,701	\$42,599,405
Gold	15,980,170	13,463,898
Total	\$93,463,871	\$56,063,303

It is stated that the Mexican government is at present buying all the silver presented, paying either in gold coin or with sight drafts against New York, at New York quotation. All silver delivered to the Government is free of export tax. The sale of Mexican silver in the City of Mexico, therefore, results in less expense to the seller, as it costs less to deliver it there than to deliver it in New York. This open market for silver should have a good effect on the industry, as most of the silver produced in Mexico is thus removed from New York and London markets.

JULY COPPER SALES

July sales of copper, both foreign and domestic, totaled about 75,000,000 lb. This is about 35,000,000 lb. larger than many important sellers believed the total would be. July production of primary copper for American refining was about 45,000,000 lb. During the last week of the month about 45,000,000 lb. of copper was sold, mostly at prices between 12½ and 12c. per pound, delivered. Recently one wire company is reported to have purchased 1,000,000 lb. at 11½c. Domestic and foreign sales are small at present, with buyers awaiting further indications of price trend.

GEORGE GRAHAM RICE AND THE BLUE SKY LAWS OF CALIFORNIA

In response to a request for a statement in reply to a telegram from the Utah Securities Commissioner, indicating that he has appealed to the U. S. Attorney-General to take action against the California Commissioner for violating the Sherman Anti-Trust Act, in endeavoring to prevent the sale of Bingham Galena mining stock in California until the company shall obtain a permit from the California Commissioner so to do, Commissioner of Corporations E. C. Bellows has issued the following statement:

If there was any probability that action, as requested, would ever be taken, I should defer discussion until a judicial finding had been rendered; but feeling certain that newspaper publicity is all that is being sought, silence on my part might cause Californian investors to be misled, to their financial injury. This department has never questioned the authority and the right of the Utah Commissioner to issue permits, or to supervise the sale of securities in his own State; but when he diverts his talents to the supervision of the stock sales in California he is acting outside of his jurisdiction. He has full power to refuse the sale in Utah of stock authorized in California or any other State, provided such sales violate the Act he is administering; but to contend that securities he has legally authorized in Utah can be sold in other States, in straight violation of their Blue Sky laws, is to hold that every Blue Sky law is null and void with respect to supervising the sale of issues from Utah, a position too puerile and foolish for serious consideration.

The Corporate Securities Act of California provides that: "No person, partnership, association, or corporation, other than a broker holding a broker's certificate, then in effect, shall issue, circulate, or publish any advertisement, pamphlet, prospectus or circular concerning any security, to be issued by any company, that such person, partnership, association or corporation desires to sell, until the company proposing to issue such security shall have first secured from the commissioner a permit authorizing it to issue or sell such security." (Section 7.) Section 2 of this Act defines the word "company" as including both domestic and foreign organizations, and Section 5 makes it unlawful for a broker to operate within this State until he shall have applied for and received a certificate from the Commissioner of Corporations authorizing him to do so.

Neither the Bingham Galena Co., whose stock was offered for sale by circular to many working people in California, nor Child, Barclay & Co., the brokers who sent out the circulars, nor George Graham Rice, the promoter, has received the required authorization to operate in California. They, therefore, have incurred the penalties prescribed in Section 14 of the Act, which provides that anyone who "willfully violates or fails to comply with any of the provisions of this Act . . . is guilty of a public offence and shall be punished by imprisonment * * * not exceeding five years * * * or by a fine not exceeding five thousand dollars, or by both such fine and imprisonment".

Being charged with the duty of administering and en-

forcing this law, and having evidence of its violation, I deemed it my duty to bring the matter to the attention of the district-attorney of the county in which many recipients of the unlawful circulars resided. This constitutes what the Utah Commissioner is pleased to term, "conspiracy in restraint of inter-state commerce". He does not seem to recognize the right of California to supervise the sale of securities within her own borders, but apparently deems a demand for compliance with our statutes a reflection on his acts, and a discrediting of securities issued in his State.

COPPER AND BRASS RESEARCH ASSOCIATION

R. L. Agassiz, president of the Calumet & Hecla Mining Co., has announced the formation of the Copper and Brass Research Association, an incorporated organization of the copper, brass, and copper-alloy interests. The purpose of the organization is to stimulate the use of those metals. Membership in the association is open to producers of copper sold here or selling-agents of copper in the United States; to fabricators of copper, brass, and copper products generally in the United States and Dominion of Canada, and to others directly engaged in or connected with the copper and brass industries.

The officers of the association are R. L. Agassiz, president; Fred S. Chase and C. F. Kelley, vice-presidents; Stephen Burch, treasurer; W. S. Eckert, secretary. William A. Willis has been appointed manager of the association, which has offices at 25 Broadway.

A. S. & R. LOSSES

The American Smelting & Refining Co., with principal offices in Omaha, lost \$1,000,000 last year because of the business depression, according to claims made in an appeal from assessment of the board of equalization filed in the district court there. The company asks that valuation of its personal property be restored to \$1,200,430, the valuation made in its own report on April 1, 1920, instead of \$2,129,600, arbitrarily set by the equalization board as a fair valuation.

ALASKA

Hyder.—The Fish Creek Mining Co. is doing substantial development on its claims, situated in the Solman River district about a mile from the Hyder-Premier road. A promising vein of ore is reported to have been uncovered through the blasting necessitated in laying the foundations for one of the towers of the Premier mine's aerial tramway.

CALIFORNIA

Jackson.—Within a month the Kennedy mine will resume its position among the gold producers of California. Retimbering of the shaft has been completed, lower workings have been repaired, and preparations have been made for resumption of mining on the 3700-ft. and deeper levels. The Kennedy has been idle for about three years, the result of labor shortage, high operating costs, and damages to the mine by fire and water.

Oroville.—A discovery of rich gold-silver ore near Yankee Hill, in the vicinity of Lost lake, is reported by B. F. Clark and John Wells. The ore has been exposed in two places and appears to be an extensive deposit. The discoverers are making plans for comprehensive prospecting.

Two veins of gold ore have been uncovered in the Wyandotte mine near Oroville. The manager states the quartz was picked up within 2 in. of the old tunnel, which failed to reach the veins several years ago. A mill surface plant and other equipment have been erected and arrangements made to send the 120-ft. shaft to a depth of 300 ft. The Wyandotte is controlled by J. A. Coutts of San Francisco.

Randsburg.—California Rand Silver reports progress for the week ending August 8: main shaft drifts 150 ft., cross-

cuts 25, raises 35, 11th level, L pocket, 29; a total of 194 ft.; No. 2 shaft 24 ft., pocket, 12; water shaft at Indian wells 16 ft.; total for all 246 ft. Three cars of timbers and machinery have arrived for the 100-ton mill, also the first car of steel for the water-tanks. The company intends to erect a new duplex two-stage 1300-ft. air-compressor. The payroll is 101. Grady lease, on California Rands ground, is sending 12 cars per week to the smelter. Mr. Alderson states that they are now finishing the cutting of the station at 500 ft.; this will be the principal level, with blower, motor, and telephone.—Bisbee and Brey, lessees on the Osdiek claim, are now down 400 ft. and will cut a station at that level. On the third level they are drifting west.—On the Silver Reef group, the International diamond-drill company, of San Francisco, has the contract from Flynn and Elkins, Eastern mining capitalists, to sink a series of holes.

Edward Grady, of the Grady lease, has bonded the Sunset and Utopia group of 10 claims, south of the silver mines.—With a heavier engine, head-frame, and hoist, the Silver Moon lease will resume sinking from the 100-ft. level.—Julius Schede is sinking all the way on fair milling ore, in the Silver Bar lease.—Errecart and Lombard have their Ingersoll-Rand compressor on the K. C. N. lease and have resumed sinking. J. W. Hicks, in the adjoining block, is drifting north-east at 180 in good looking silver ore.—In the gold end of the Rand district, Mr. Nicolson, of the Yellow Aster, has added 5 stamps to the mill and hopes to have 30 stamps dropping continuously.—The Big Butte mill is now running on a good grade of ore from the Blackhawk.

Edward Shipsey, president of the King Solomon group, is here from Pasadena. At present the company has not decided on future developments. Mr. Hall, superintendent of the North Rand Silver, is expected home in the next few days. George Kaar is doing a lot of prospecting and development in the Gold Coin. He is likewise busy on a group of gold and silver claims situated near the Blackwater wells, 20 miles east of Randsburg.

Redding.—The Hazel Gold Mining Co. has given an option on the Gladstone mine near French Gulch to a San Francisco company, which has placed Hamilton Eddie in charge as superintendent. A small force of men has been set at work cleaning out the drifts and getting ready for active work. The Gladstone was shut-down in 1916 on account of the war prices for material and labor.

COLORADO

Cripple Creek.—July production of the Cripple Creek district as reported from the Golden Cycle, Portland, and Lincoln companies' mill totaled 39,592 tons with a gross value of \$394,580.78.

The Home Run mine is again active, under lease and bond. The property will be operated by Byron Caley.—The sub-lessees of the Victor Gold Mining Co. are mining a fair grade of milling ore on the 3rd, 7th, and 9th levels and shipping about two cars weekly.—Owner Roberts, lessee of the El Paso Gold King, in Poverty gulch, is again shipping.

Idaho Springs.—The Palisade Copper Co. has resumed operations at the Wheeler mine in East Argentine, and has a force of miners developing a vein of gold-silver ore, 12 in. wide, containing \$200 per ton.—The Waldorf mill is being re-modeled; flotation will be used.

Leadville.—The Cleveland, Little Winnie, Virginia, Jessie Clark, Katy, Treasure Vault, Australian, Midnight, Mosquito, 1392, Yale No. 2, Yalu, and Yamagata lode mining claims in the Leadville district, owned by the New Monarch Mining Co. were sold at sheriff's sale last week, to satisfy a judgment held by the First Trust & Savings Co., and were bought in by the plaintiff corporation at \$72,396.67.

Silverton.—A new silver-lead orebody is reported to have been opened up on the Joe & John group by the Golden Consolidated Mines Company.

IDAHO

Coeur d'Alene.—In our issue of August 13 it was stated that a bond had been taken for a reported consideration of \$80,000 on the Terrible Edith mine, by H. A. Morse, a mining engineer of San Francisco. This was incorrect. Mr. Morse's connection with the property is well known, but our correspondent was in error in regard to the facts of the transaction.

NEVADA

Goldfield.—The shipment made on August 3 from the Donals and Giles lease on the Florence contained 61.96 tons, containing 7.51 oz. gold and 3 oz. silver per ton, or a gross value of over \$9000, according to a control assay. Another rich shipment is expected to be made in a few days. This was the second shipment since the orebody was found in the hanging wall of the old Reilly flat stope.

Simon.—Indications are that the power-line to the Simon Silver-Lead will be completed and that the plant of the company will be started on October 1.

Tonopah.—The strike that started April 16 in the Tonopah and Divide districts has been settled, the miners calling off the walk-out and returning to work on the terms of the operators, as had been foreseen practically from the beginning of the trouble. The wage reduction they have accepted amounts to 12½%. The first move to end the strike was made by the hoist engineers; their vote was followed by that of the electricians, blacksmiths, and miners.

WISCONSIN

Cuba City.—At the National Zinc Ore Separator plant, the kilns used in drying the crude zinc concentrate have been re-lined, and the Cottrell precipitators have been made ready for service. Official announcement is made of a resumption of operations on August 15. It is the intention of the National management to run steadily after the tie-up has been terminated.—The Zinc Hill Mining Co. remains shut-down. The Connecting Link Mining Co. has developed some zinc-ore deposits at mine No. 2; shipments of lead ore were made the first week in August, the price paid being on a base of \$47.50 per ton, 80% metallic content.

Livingston.—Renewed hope prevails in zinc mining circles over recent developments in the zinc-lead district of Wisconsin. The Vinegar Hill Zinc Co. resumed operations at the Yewdall mine after a brief shut-down; 50 miners and mill-men are now employed. The recovery of zinc concentrate, averaging 25% zinc, amounts to 300 tons weekly. Shipments to the National Zinc Ore Separators, at Cuba City, are being made at the rate of four to six 40-ton cars weekly.—The Coker mines, No. 1-2-3, will soon resume operations. Mining machinery has been consigned to the nearest point of delivery, and the pumping stations will be rigged up for active service. Former employees believe it will require at least two months to unwater all three mines. Mules heretofore used for underground tramping will be supplanted by electrical apparatus.

Mineral Point.—The recent announcement of a reduction in the various brands of oxide by the New Jersey Zinc Co. has had the effect of stimulating business to a marked extent. Shipments of oxide are made daily in lots of considerable size; warehouses, congested some time ago, are showing the effect of lower prices. However, oxide even at the new prices is higher than before the War, and further reductions would accelerate business to the proportions usually obtaining at the big plant at Mineral Point. Two blocks of furnaces, each 12 double-compartment, force-and-down draft, are running on 24-hour schedules; mining men are encouraged in the belief that soon the Mineral Point Zinc Co. will come into the market for supplies.

UTAH

Alta.—Operations are being carried on at the Emma mine by lessees and on company account. A recent shipment averaged 35 oz. in silver and 8½% lead. Development work is being done.

Eureka.—George A. Udall has filed suit in the Third District Court at Salt Lake City against the Tintic Eastern Mining Co. to recover 200,000 shares of stock, alleged to have been wrongfully taken for assessments, and \$5000, alleged to be due for services as general manager.—The Chief Consolidated Mining Co. is cutting a station at the 1600 level in the No. 2 shaft, and proposes to start a development campaign at that depth. The shaft was sunk to the water level, or 1880 ft., and is connected with the older workings by a drift.—The management of the Centennial-Eureka mine has awarded a contract for a continuation of the long drift on the 1800-ft. level.—Recent work at the Iron Blossom mine has resulted in the discovery of new orebodies above the 600 level, according to E. F. Birch, local manager of the Knight interests.

Park City.—What is believed to be the highest grade ore yet found in the Silver King Consolidated mine was discovered recently in the south-west end of the Iron drift, which extends to the right of the Spiro tunnel, about 13,400 ft. from its portal. Average assays show returns of \$16 in gold, 170.8 oz. in silver, and 33.3% lead, with a small amount of antimony. On the basis of present metal quotations, this is equivalent to about \$272 per ton. The Spiro tunnel is being driven forward at an average rate of 4½ to 5 ft. per day, and a second shift is to be added to hasten the work. Two headings are being driven on the 175-ft. level for prospecting purposes.—During June and July, no development work was done at the New Quincy mine. About August 1, operations were resumed. In a winze from the 900 level, near the Little Bell shaft, a streak of high-grade ore has been encountered. At present the ore is about 2 ft. in width, and averages 50 oz. in silver and 15% lead.

BRITISH COLUMBIA

Cranbrook.—The Columbia section of the A. I. M. & M. E. will hold a meeting here from August 21 to 24. Points of interest, including the Sullivan mine, will be visited.

Nelson.—At a recent meeting of Utica Mines, Ltd., the former directors and officers were re-elected. The directors considered a proposal by a syndicate that was desirous to obtain a five years lease on the mine, and was prepared to carry out development work to the value of not less than \$3000 per year and to pay the company 15% royalty on all ore mined and shipped. The syndicate was prepared to put up a cash deposit of \$5000 as a guarantee that it would carry out the provisions of the lease. It is understood that Thompson & McKinney, who operated the North Star mine at Kimberley for a considerable time, are interested in the syndicate, and that they will undertake the management of development work in the event of a lease being granted.—Edward and Sarkis Tergian have struck a promising vein at Markin Spur, and have drifted 20 ft. on it. The vein is 2 ft. wide and is said to average \$10.40 per ton in gold.—Considerable dissatisfaction is being expressed by mining men in the Slocan camp at the Railway Commission for allowing the C. P. R. to reduce its service to the district to a tri-weekly one. The Slocan camp has had a pretty hard furrow to plow for some time, and this seems to be a further obstacle in the way of progress. The ore receipts at the Trail smelter for the last ten days of July totaled 12,761 tons, all but 265 tons coming from the company's own mines. This brings the total for the year to date to 243,143 tons.—It is understood that the White Bear Co., a subsidiary of the Consolidated M. & S. Co., which owns the White Bear mine, at Tinsland, is about to reopen that old producer.

The Consolidated company evidently desires to push its gold output to the limit during the present slump in base-metal prices.

Prince Rupert.—George Clothier, resident mining engineer, recently made a trip into the Atlin district and reports that the discovery of placer gold in the Little Atlin Lake district caused a stampede recently from a number of local centres. Subsequently developments proved that there was no occasion for excitement. There are more men on the long-exploited creeks of Atlin than for the past two or three years. Individual miners are making good wages and there have been several fair clean-ups. The smaller creeks now are beginning to show well. As to lode mining, the inactivity of the Engineer mine, because of litigation, is hold-

at Monclove, in which district the mines are situated. — Los Placeres Mining Co., with headquarters in Saltillo, has called for a meeting of stockholders to take place at their offices on August 29. — Torreon parties have filed on the Agulla group of mines in the Jimulco copper district. The new property is situated near La Sultana mines in the Jimulco mountains. — Miners in this district are again complaining of the lack of railroad facilities, a condition which they claim is growing worse instead of better. They are handicapped in shipments of both ores and supplies.

Torreon, Coahuila.—Heath Steele, general manager, and Dr. Sussman, president, and other officials of the Penoles Mining Co., have been inspecting the smelter plant here this week. They will visit a number of mining properties and

Utah Copper Mine, Blingham, Utah

ing back progress. With the opening of this property Mr. Clothier looks for general mining improvement. — A substantial mining company has optioned J. N. Ruffner's group of claims on Fourth of July creek, on which there are good surface showings of silver-lead ore. — While passing through here recently, H. S. Munro, general manager for the Granby Consolidated company, stated that everything was satisfactory except the price of copper. The roof of the ore-bins was being repaired. The company lost little in output through the fire, the damage of which was estimated at \$30,000. Mr. Munro said that the price of living had dropped 35% at Anyox since the beginning of the year.

Victoria.—Title to the Engineer mine, at Atlin, is in the courts, once again, the point in dispute being the genuineness of the signature of Captain Alexander to the document by which he is said to have willed the property.

MEXICO

Saltillo, Coahuila.—The Cia. Minera Desarrolladora y Explotadora, of which William E. Quinn is secretary and treasurer, recently held a general meeting of shareholders

the Mapimi smelter on a general tour of inspection.

The smelter here is still operating three lead- and one copper-furnaces. It is reported, however, that no outside ores are being received; the plant will probably close down indefinitely after September 1. After this, the Monterrey smelter No. 2, which is owned by the company, may possibly be blown-in. In this event the heads of the departments will be transferred from Torreon. — A line is being constructed from the station of Rivas on the main line of the National railways to the Ramirez mountains in the vicinity of San Juan de Guadalupe. The road is being built by Albert Genty, owner of the Calaverita mines. It will be completed next month, when large shipments of ore will be made from the camp to the smelter at Aguascalientes. — Work is to be pushed on the new railroad line being constructed by Smith Bros., from Tepchuane to the Guanacevi mining camp. It is expected that the construction will be completed by the end of this year. — A number of mining men of this district are in Mexico City this week to confer with President Obregon in an effort to rehabilitate mining conditions in general.

ONTARIO

Cobalt.—The economic situation in the silver-mining industry has lately shown some improvement with the strengthening of the price of silver and the downward tendency in the cost of material. High freights and the cost of labor still remain obstacles to the resumption of operations by several of the mines, which are expected to re-open as soon as the outlook becomes somewhat more favorable. During the first half of 1921, Cobalt mines paid dividends amounting to \$1,050,000, making a total up to date of \$85,531,066.—The Hudson Bay will resume operations this month. It is the intention of the management to treat all the ore that has been broken, following which they will decide whether it is advisable to engage in a campaign of further exploitation and development, or close down.—The mill of the Mining Corporation of Canada is treating a greater tonnage than ever before in its history. The ore contains an average of about 20 oz. silver per ton, and the mill is handling approximately 300 tons daily.—The La Rose Consolidated has re-opened its Violet property adjoining the O'Brien and begun active development.—During July the Bailey Silver Mines shipped 1262 tons of ore. The Bailey custom mill was operated at full capacity and treated 4043 tons of ore, realizing gross earnings of \$12,129. Changes in the mill have made a higher percentage of recovery possible. The stopes at the 5th level of the mine are being timbered.

Larder Lake.—The big three-compartment shaft of the Canadian Associated Goldfields is down 350 ft.; cross-cutting has been started on the 175- and 320-ft. levels. The company has solved the transportation problem by the use of a caterpillar tractor, capable of carrying 11 tons, which has reduced transportation costs about 50%.

Porcupine.—The Dome Mines, during the three months ended June 30, realized net profits of \$235,697, or at the rate of a little over 20% on the issued capital, which compares favorably with the best previous records of the mine. Operations at the lower levels have been so favorable as to make it possible to treat a grade of ore much richer than in former years, and the old rate of profit distribution of 20% per year promises to be exceeded shortly. In the meantime it is officially intimated that the dividend rate of 10% will be continued, and that further distributions will take the form of capital return.—A contract has been let for several thousand feet of diamond-drilling on the Gold Island property in the Nighthawk Lake district, of which A. R. Globe has been appointed manager.—At the Beaumont, lateral work is being started at the 300-ft. level to tap veins indicated by diamond-drilling.—The management of the Triplex has decided to sink two shafts, one vertical and the other inclined, to a depth of 500 feet.

South Lorrain.—The Keeley mill, which was temporarily closed owing to the burning of a motor, is again in full operation.

YUKON TERRITORY

Mayo.—Activity is being shown in the Keno Hill district, more than 2000 claims having been staked. Among the big companies that are interested and that have representatives in the field are: The Yukon Gold Co., Bunker Hill & Sullivan interests, and the Consolidated Gold Fields of South Africa. The last recently has staked 40 claims. Edward K. Jones and associates have recently staked claims on Galena hill, where they claim to have found a 20-ft. body of ore. Indications seem to point to prosperity coming back to the Yukon through its silver-lead deposits. At a recent plebiscite the Territory voted down prohibition by a two to one majority.—The Coeur d'Alene mines of Idaho are reported to have secured options on three large groups of claims in the Keno Hill district of the Mayo camp.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

P. P. Lietzow has moved his headquarters to Las Vegas, Nevada.

George C. Crowe, of Marysville, was in San Francisco recently.

S. H. De La Mare has returned from Khartoum, Sudan, to Sussex, England.

Norman Carmichael, of Clifton, Arizona, is at Victoria, British Columbia.

R. B. Tempest, assistant chief engineer to the Utah Copper Co., is at Denver.

Nelson Dickerman has left New York on his way to Paramaribo, Dutch Guiana.

Walter Stalder has returned from an oil-land inspection in south-eastern Montana.

James F. Calibreath, secretary of the American Mining Congress, is at Uintah Basin, Utah.

C. W. Whitley, vice-president of the American Smelting & Refining Co., is at Salt Lake City.

C. A. Richardson, manager of the Chambers-Ferland mine, at Cobalt, Ontario, is now in London.

Edward Higgins has returned to San Francisco after a visit to the iron and copper mines of Michigan.

K. Yoshizawa, mining engineer to the Mitsui Mining Co., was in San Francisco on his way to New York.

J. T. Grayson, we are glad to say, is out of the hospital and convalescing at his home in San Francisco.

John T. Reid has returned to Lovelock, Nevada, from New York, where he has been for the last five months.

George W. Heintz, of Boston, vice-president of the U. S. Smelting, Refining & Mining Co., is at Salt Lake City.

Richard B. Moore, chief chemist to the U. S. Bureau of Mines, was here this week, and is now at Reno, Nevada.

N. P. Dare is now the manager for the Chenderiang Tin Dredging Co., in the province of Perak, Federated Malay States.

Richard L. Lloyd, of the Dwight & Lloyd Metallurgical Co., has been granted the degree of M.Sc. of Washington University, St. Louis.

Alfred James has resigned from the council of the Institution of Mining & Metallurgy, of which society he was at one time the president.

William Kemnitzer has returned to Palo Alto from Nevada, where he studied the evidence of seismic action as an assistant to Dr. Branner.

Jose Zukany, manager for the Placeres de Oro de Michoacan and the Placeres de Oro de Bacubirito, in Sinaloa, Mexico, is at the Palace hotel.

B. G. Hood, president and general manager for the Canyon Queen Silver Mining & Milling Co., of Reno, Nevada, was in San Francisco this week.

Arthur B. Parsons, Associate Editor of the 'M. & S. P.', visited the Kelly mine, at Randsburg, California, last week. He went from there to Tonopah.

Heinrich O. Hofman, Professor of Mining in the Massachusetts Institute of Technology, has been elected to honorary membership in the Institute.

A. J. M. Sharpe has retired from the managing directorship of H. S. Willcocks & Co., to take over the direction of the International Metal Service, in London.

James G. Ross, consulting mining engineer for the Milton Hersey Co., of Montreal, has returned from an extended examination trip to the northern interior of Quebec.

THE METAL MARKET

METAL PRICES

EASTERN METAL MARKET

(By wire from New York)

August 15—Copper is inactive but steady. Lead is quiet but firm. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

THE OUTLOOK IN BRITISH STEEL

British steel manufacturers are staggered by the magnitude of the difficulties they now face, states 'The Iron Age'. The coal strike has been settled, but iron and steel manufacturers cannot go ahead at the high prices they must pay for fuel. The boom of 1919 and its overhang in 1920 pushed the British steel market pounds per ton above what German, Belgian, and French makers were willing to do. After the coal-strike settlement, British prices came off from £3 to £5 per ton, but they are still so far above those named on the Continent as to put British works out of the running as to most of the current export trade. In a recent statement issued jointly by the National Federation of Iron and Steel Manufacturers on behalf of employers and the Iron and Steel Trades Confederation for the workmen, the opinion was expressed that "in view of foreign conditions the industry will not be able to export unless fuel as well as other items of cost are reduced to a level not higher than from 75 to 100% above pre-war". The statement further says that the difficulties now confronting the industry "are not of its own making nor within its control; they exist largely from political causes and appear to us to require Government attention".

The London 'Ironmonger', in commenting on this statement, expresses surprise that the steel industry, "which was among the first to demand the cessation of all Government interference, should now begin to talk of Government assistance".

There is no question that high fuel and labor costs will continue for a long time to be a serious handicap to British steel manufacturers in the export trade. Production of British steel will not resume on any scale until the price of coal comes down 50% or more and it will be many a day before such a drastic readjustment can take place, with the control of coal production and prices so largely in the hands of the labor unions. It seems likely, moreover, that Continental steel will be increasingly a factor in the British market. There is scarcely a quotable market, in fact, in British material, the business done being in the smallest quantities and from accumulated stock. The nearest approach to the real steel market in Great Britain today would be the quotation of prices now being paid there for Continental iron and steel.

It is true that the British steel industry has always pulled through—just as the nation has been able to pull itself together when there seemed nothing ahead but disaster. Doubtless the way will be found at length out of the dangers that now loom up so threateningly; but it must be said that the pessimists have most of the facts on their side as the case stands today.

MONEY AND EXCHANGE

Foreign quotations on August 16 are as follows:

Foreign quotations on August 16 are as follows:	
Sterling, dollars: Cable	3.65
" Demand	3.64 1/2
Francs, cents: Cable	7.72
" Demand	7.70
Lire, cents: Demand	4.33
Marks, cents	1.11

Eastern Metal Market

New York, August 10.

"Stationary as to price but slightly more active as to demand", characterizes all of the markets.

The bottom of the copper market is believed to have been reached, and buying at present levels is better.

Demand for tin is moderate. Prices have advanced.

The tone of the lead market is better, and buying is on the increase.

Inquiry for zinc has developed and there have been more sales.

IRON AND STEEL

The moderate improvement of the past two weeks in replenishment demand for steel continues, but few successors have appeared to the larger-sized orders that lately brought out such keen competition in the Central, Western, and Chicago districts, says 'The Iron Age'. Any new price concessions have been in pig-iron rather than in finished material.

Steel, like pig-iron, fell off 20% in July from the output in June. The ingot statistics published this week show 803,376 tons produced by 30 companies last month, indicating 950,000 tons for the whole industry, against 1,190,000 tons in June. The July rate represents about 11,500,000 tons per year, as against a rate of 30,000,000 tons per year in January and an actual output of 40,881,000 tons in 1920.

On larger buying than in many weeks pig-iron in eastern Pennsylvania shows a fresh decline of \$1 to \$2 per ton. The largest lot was 5000 tons of basic bought by an Eastern steel company at \$19 at furnace. Foundry iron also went to a new low level for the year, considerable sales being made at \$18.50, eastern Pennsylvania furnace, for No. 2 plain and \$19 for No. 2X. Lower quotations are reported also from the Buffalo district, No. 2 being offered considerably under \$19.

German and other European bids on steel for Japan are well below American prices. French sheet bars have been offered at \$34.70, delivered in Japan, or \$11 to \$12 under anything domestic mills would do.

COPPER

Attempts by consumers and dealers to break the 12c., delivered level for electrolytic copper by bidding 11.75c. have proved futile. Inquiry, partly with this object in view, has been plentiful; it is now stated by one or two sellers that such inquiries have resulted in moderate sales at 12c., delivery, which seems to be bottom at which any one will sell. Some large producers, however, will not quote at all, and announce they are out of the market. It is believed by those who are selling that 12c. marks the bottom and that possibly the turn in the trend has come or at least has started. A more cheerful feeling prevails. There has been a reduction in the ocean freight rates from \$9 to \$5.50 per ton to Hamburg, which is expected to stimulate foreign buying which at present is light.

TIN

The market is only moderately active but prices are higher, due largely to advances in exchange which took a decided jump on Monday. There were two moderately active days last week, on one of which about 300 tons of future shipment from the East was sold at 26.25c. down to 26c. and on the other about 100 to 150 tons, also Eastern shipment, at 25.75 to 26c. With the advance in prices on Monday to 27.75c., New York, there was a fair amount of business at 27.50 to 27.75c. Spot Straits yesterday was quoted at 27.75c., New York. London prices were about £1

per ton higher than a week ago, at £162 10s. for spot standard, at £164 5s. for future standard, and at £163 5s. for spot Straits. Arrivals thus far this month have been 260 tons with 4010 tons reported afloat.

LEAD

The market is a little more active, with sales on the increase rather than otherwise. The New York price of the leading interest and of the outside market is still 4.40c., at which price business is being done. At St. Louis the asking price of the leading producer is unchanged at 4.40c., independent sellers quote 4.20c. with the tendency upward.

ZINC

Sellers report a better tone and are more sanguine than in some weeks. Inquiry from galvanizers and brass makers, particularly the former, is more active and of a more substantial and definite character than in some time. This has resulted in sales of moderate proportions for both August and September delivery. There is still some prime Western available at 4.20c., St. Louis, but it is believed to be fast disappearing. Some sellers report sales at 4.20 and 4.25c., St. Louis, for August delivery, with September about five points higher.

ANTIMONY

The market is quiet and unchanged at 4.60c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted by the leading producers at 24.50c. per pound f.o.b. plant, for wholesale lots for early delivery. The same grade imported is quoted at 21 to 23c., New York.

ORES

Tungsten: The market is unchanged and prices are nominal at \$3 per unit and upward, depending on the grade and the delivery.

Ferro-tungsten: Ferro-tungsten is quoted at 55c. per pound of contained tungsten in lump form, guaranteed as to quality.

Molybdenum: The market is without life, and quotations are unchanged at 55c. per pound of MoS₂ in regular concentrates.

Manganese: For high-grade foreign ore, quotations are nominally unchanged at 22c. per unit, seaboard.

Iron-Manganese Alloys: There is more life in the ferro-manganese market, and sales of about 500 tons are reported, mostly at \$70, delivered, which is the prevailing quotation for domestic alloy. British sellers are now quoting \$65, seaboard, but are taking few orders. Business in spiegeleisen is confined to small lots at \$25 to \$27 per ton, furnace.

Ferro-silicon, 50%, is a little firmer at \$65, delivered. Those who have sold as low as \$60 are inclined to withdraw this price.

According to the report of the representative in Mexico of a large American bank, economic and political conditions there are good and progress under the present administration rapid, states 'The Iron Age'. Train schedules throughout Mexico are greatly improved and receipt of the locomotives and rolling-stock purchased in the United States recently is expected to relieve all congestion at the ports. He adds that the administration is preparing to make payments on all foreign debts.

T. A. RICKARD, Editor

IN our news columns will be found a brief account of a remarkable record in shaft-sinking made by the Walter Fitch Jr. Company, at Eureka, Utah. A three-compartment shaft was sunk and timbered for a distance of 427.5 feet in 31 consecutive days, making an average of 13.8 feet per day. The best previous record is believed to be the performance of the Crown Mines, Ltd., at whose mine 310 ft. was made in a 31-day period two years ago.

OUR issue of August 13 contained a letter signed "E. M. West", attacking the Cornucopia Divide Mining Company. This letter, we now learn, was a gross breach of good faith; the signature was a fake, the writer being Albert Erickson, who vented a personal spite in attacking the controllers of this company, which, we find, is operating under a permit from the Commissioner of Corporations and is directed by worthy citizens, among whom we may mention Mr. P. W. Pray, president, Mr. J. C. Downey, treasurer, Mr. C. E. Butler, Mr. W. B. Harrington, and Dr. W. F. Schwarnar, all business men of Oakland. We apologize for publishing the letter attacking this company.

UNDER 'Discussion' this week we publish a particularly useful and public-spirited letter from the Dean of the College of Mining in the University of California. It is on the subject of indexing, which was discussed recently in these pages. Then comes a protest from Mr. Harai R. Layng, who objects, quite properly, to our omission to take note of his contributions on the subject of volatilization. We apologize unhesitatingly. The proposed revision of the mining law is again criticized feelingly by sundry readers to whom it is a matter of personal interest. Mr. George L. Sheldon, of Denver, is an 'old-timer' whom we know personally to be a genuine prospector and 'mining man' of the best type. He objects, as others have done, to the proposed regulation compelling the description of locations in terms of cardinal lines. He believes that the change would be hard on the average prospector and would handicap him to the advantage of the big mining companies, which have the services of a surveyor at their command. The Mexican system of making locations is cited as one that we ought to imitate. Next comes Mr. W. K. Whitmore, of Mojave, who recites his experiences in Alaska to show how the regulations impede the real adventurer to whom the expansion of the mining industry is so largely due.

With his attack on the trading and transportation companies in Alaska we sympathize, because we have personal acquaintance with the conditions obtaining on the Yukon. Undoubtedly they did kill the goose that laid golden eggs for them, for they hindered the exploration and development of the region in the years that are past, and exercised power in an arbitrary and selfish way. As to the location of groups of claims by one man under power of attorney, that is an abuse of the law to which the real prospector and any other good citizen has every right to object vehemently. It has hindered the advancement of Alaska and has been instrumental in bringing it to its present low state of industrial activity. Another contributor, Mr. F. J. Kirby, imputes the decay of prospecting to legal red-tape. He makes several radical suggestions. Mr. G. L. Holmes, writing as a mining engineer, endorses the prospector's plaint, for he believes that the new regulations will play into the hands of the land-grabber. He recites an incident from his own experience to show how the cheaper kind of mining stock is boosted on the local exchanges. He also objects to the location of claims in accord with the subdivisions of the Land Office, and suggests that there can be too many legal tangles in regulations that ignore the eccentricities of ore deposits. The most important point to which he draws attention is the inevitable conflict between the old and the new law, when the old apex rights come into conflict with the proposed 40-acre tracts without extra-lateral privileges. To us this objection seems logical.

MANY a mining enterprise has suffered serious loss as a result of stupid orders sent from Eastern offices by officials who knew little or nothing of local conditions at the mines. Early this month about 215 men, comprising the entire force of miners, mechanics, and construction laborers at the property of the Darwin Silver Company, in Inyo county, California, were summarily discharged and paid off at the direction of a representative from the administrative office at Chicago whose mission, according to reliable information, was unknown to the operating officials until his arrival at the mine. Any engineer who is familiar with operations in such an isolated district can realize the demoralization that ensued. Darwin is 40 miles from Olancha, a station on the Southern Pacific Company's branch line from Mojave in California to Sodaville in Nevada. The road connecting the mines with Olancha is at present about as bad as can

be imagined, and Olancha itself is a night's journey from Los Angeles, the nearest large city. The wholesale migration from Darwin is pitiful. There are no operating mines or large construction projects in the vicinity of Darwin, with the exception of the California Rand silver mine at Randsburg, and no considerable number of additional men are required there. The hardship that this unexpected shut-down brought upon the employees is accordingly apparent; and of more importance to the enterprise itself is the bad reputation that will necessarily attach to the company and its operations. The company had just completed a 50-ton pilot mill, preliminary to the erection of a 300-ton plant for the treatment of its lead-silver ore; it had begun the construction of commodious boarding-houses and warehouses, as well as various shop-buildings and staff quarters; and it has on hand new machinery and equipment valued at several hundred thousand dollars. The total investment for improvements during the last two years is probably more than a million dollars. According to the last report of Mr. E. W. Wagner, the president, the mines themselves have been commended by Messrs. Robert W. Hunt & Co., of Chicago, and by Mr. A. G. Kirby, who is now general manager for the Darwin Silver Company. It is possible that financial difficulties made a temporary suspension of operations unavoidable, but we have reason to believe that such was not the case. In our opinion the order would not have been given if the officials at Chicago had had sufficient experience to realize the difference between discharging 215 men at Darwin and discharging the same number at Chicago. Their mistake was the failure to consult with the manager at the mine.

The Status of Silver

In commenting on Senator Pittman's remarks, made recently at a meeting of the Mining & Metallurgical Society of America, and reproduced elsewhere in this issue, on the history and status of silver during recent years, Mr. C. W. Handy drew attention to the demand for silver, from the geographic and economic aspects. The United States, he pointed out, is young as compared with European countries, but the latter are young as compared with the Far Eastern states of China and India. Civilization had advanced in the Far East for centuries before Europe made much progress, and has handed down its customs to the present generation. Starting with the custom of bartering goods for goods, the Orientals advanced to the exchange of goods for rare stones or metals, finally adopting silver or gold as standards of value and means of exchange. These were adopted for the same reason that today we find them convenient for the same purpose. To appreciate the demands of those countries, it must be remembered that the population of China is estimated at about 400 millions, and that of India at 335 millions, all trading to some extent, but uneducated to modern methods of finance. A dollar placed in the bank has no significance to the majority of these people; they want, and they de-

mand, hard metallic money that they can see and feel and use when they wish to buy. The British government has been educating the Indian people gradually to use the rupee note instead of silver; but as yet only 418 banking houses have been established to serve over 300 million people. The old customs are hard to change. The people want the silver; and, having obtained it, it disappears forever, or until hard times force some of it on the market, in the form of coin or jewelry. In China, Mr. Handy added, the monetary unit is not a coin. A weight of silver called a tael (outside the country) is the basis of exchange; but there are about 65 tael standards in use. These vary in fineness as well as in weight, thus involving complications in exchange dealings. Although the rupee is the unit of value in India, a great deal of misconception arises outside that country, because India regards the question as one of bullion rather than of currency. The people choose to set their own ratio between gold and silver currency. These two metals are looked upon as commodities, and the imprint of a die is only an official certificate as to contents. From this conception it is easy to understand why Great Britain had difficulty in educating the Indians to the use of paper currency, and why she has permitted those people to melt their coins into bullion when they wish to do so, a privilege that is denied to the citizens of the mother country.

In addition to the extraordinary demands of India for silver during the War, as pointed out by Senator Pittman, Mr. Handy showed that the requirements of China were abnormal. This country, during the earlier stages of the contest, had sold silver to India at a high price, and needed to replenish her stock. Russian paper rubles, which had been used in northern China, became valueless; silver had to be imported to take the place of that depreciated currency. The present low price of silver in the world's markets is the point of chief interest. Ordinarily, the law of supply and demand determines the price of any commodity, including silver. The demand exists throughout the Far East, as it exists in all European countries. With so small a supply of silver, why the low price? Simply this: those countries desirous of obtaining silver have little or nothing with which to purchase it. Trade is now strongly against India, as we pointed out in a recent issue; hence no silver is bought and sent there to liquidate balances. There is no balance in India's favor. On the other hand, India must settle her balances abroad, and that means she must ship her store of silver out of the country. Another factor in lowering the price of silver has been the quantity of melted coin that has become available of late. London reports that, in 1920, between thirty-five and fifty million ounces of melted silver came on the market, partly through the reduction of the fineness of the British silver coins from 925 to 500 parts per 1000. This is equivalent to doubling the supply of bullion in the British empire for the manufacture of its silver coins. Fear was expressed for the time that the British government might throw some of the silver on the market; this stimulated selling and caused a depreciation of market-value,

such as would not have occurred under normal conditions. Mr. Handy concluded by stating that recent advices from Europe and from the Far East indicate a condition that is not as encouraging as Senator Pittman would have us believe; but the present price of silver is so low and the supply is so small that it is difficult to see how the market can drop much farther. We note that Mr. B. Lenox Simpson, adviser to the Chinese government, has recently issued a statement to the effect that researches, instituted by the Bank of China, had resulted in the disclosure of interesting information anent the disappearance of silver coin, by hoarding, in Manchuria and in the metropolitan province of Chihli. It is estimated that, in each area, from 10 to 15 million silver dollars had been withdrawn and hidden since the coining of the Yuan Shi Kai dollar commenced on a large scale in 1914. It is concluded, therefore, that in the 22 provinces there might be hidden an amount that varies between 100 and 150 million silver dollars. The larger of the two estimates represents about 150 million ounces of silver. It is suggested that this might begin to appear on the restoration of general industrial confidence.

The Strike at Tonopah

Although the miners and craftsmen of Tonopah have officially declared an end to the strike that started on April 16, thereby accepting the full cut in wages, amounting to about 12½%, that was imposed by the companies, conditions are still far from satisfactory. The mines and mills are all in operation at maximum capacity, and to the casual observer the town and its industry seem to be thriving. The contrast with Goldfield, which for the present at least is a derelict indeed, emphasizes the material prosperity of Tonopah. But it will be many months before the premier silver-mining district of Nevada recovers from the effects of this four months strike; there exists an undercurrent of ill-will that only time can cure. If mistakes were made, and we believe they were, they cannot be undone now; but there may be profit in reviewing frankly the story of the strike with the hope that such a review may be helpful in averting or in adjusting such future disputes as may threaten or occur, not only at Tonopah but in other mining districts. Until a few years ago the mining companies at Tonopah had little serious trouble with their employees; the scale of wages was high; the mines were comparatively safe and healthful; the men generally did a good day's work; the town was not entirely free from agitators but the better element among the workers was so strong that the irresponsible element was discountenanced. Later, however, the radical labor leaders began to gravitate toward Tonopah and their followers went with them. The theory of radicalism is that no matter how high wages may be, they are too low; and that no matter how good conditions may be, they are not good enough. In due course demands were made for higher wages; not once, but several times. It is only fair to say that at first the rising cost of necessities and amusements made these increases reasonable;

but the last one, in 1920, followed a peremptory demand the justice of which was questionable, to say the least. The mining companies acceded, not, however, without protest from some who felt that compliance with demands which they believed to be unreasonable would add to the arrogance of the radical leaders. The "abject surrender", as it was called by some of its opponents, was made, but the memory of it continued to be a sore spot in the minds of many of the executives, some of whom were in Eastern offices. They hungered for an opportunity to give the miners some of their own medicine. Last spring the decrease in the cost of living prompted a general reduction in wages; the companies that mined copper, lead, and zinc made reductions that averaged between 75 cents and \$1 per shift. They had the additional argument of a poor market for their products. On the other hand, the companies at Tonopah had the advantage of the Pittman Act as well as the diminished cost of the supplies and commodities that they used in operating their mines. Nevertheless the employers felt, we believe rightly, that they were entitled to profit by these things and that they were justified in reducing wages to a point where they were in the proper proportion to the cost of living. At this time the closing of the copper mines flooded Tonopah with miners. How much influence this fact had upon the way in which the companies put the decrease of wages into effect is debatable, but it is alleged that a spirit of vindictiveness, caused by the peremptory manner in which the last increase had been obtained, found vent in the curt announcement only a few days before April 15 of the cut to take place on that date. It has been stated that the orders came from the Eastern offices of the companies and that many of the local officials would have favored longer notice and an opportunity for the miners to discuss the question of the actual drop in the cost of living. As to this we do not know, but we do know that in matters pertaining to the treatment of employees, the judgment of the men at the mine ought to be given more weight than is sometimes accorded. Whether a more politic course would have averted the strike no one can tell, but certainly it would have made the work of the radical agitator much more difficult. We are inclined to believe that the companies played into the hands of these 'leaders' by their arbitrary and sudden action.

Another unfortunate feature was the lack of unity among the companies. In a small town where there is but one industry and where the identity of individuals is not lost, it is essential for the welfare of the community that there be no antagonistic factions among the workers. The existence of such factions in Tonopah today is the result largely of the failure of the companies to act in unison. One of them did not join the others in making the cut; we are informed that the reason was that certain financial obligations had been incurred and that they could be met only by the continued production of silver bullion. It is unfortunate that some other financial arrangement could not have been made. Soon after the strike was declared another cleavage developed between

the companies. Two of them started to import miners and millmen; these they lodged and boarded in new barracks erected near the mines and at some distance from the town. The imported men naturally aroused the enmity of the strikers. The merchants and business men of the town, unable to agree as to whether they should support the striking miners or the company men, were driven into opposing camps, although most of them favored the strikers. The two remaining companies, on the other hand, preferred to close their mines and await a settlement of the strike, which under the circumstances was certain to end in a victory for the employers, although the duration of the strike itself was uncertain. Thus there were three groups among the employers. By the time the two companies who were importing men had obtained full crews, the strikers were ready to acknowledge defeat and declare the strike at an end. This they did on August 9. The two companies that had discontinued operations immediately hired such of their old men as had remained at Tonopah, together with many of the strikers from the mines and mills that were being operated by the strike-breakers. The employers who imported the new men must retain them, but they are afraid to mix the new and the old. Apparently they must continue to maintain their special dormitories and boarding-houses and the men will continue to live as in a hostile camp, hated by the strikers and shunned by the people of the town. A man known to be a strike-breaker cannot obtain a meal except in the company camp. Obviously this state of affairs is not only disagreeable to all concerned but it hurts the town. We hope that some way can be found to end the impasse. Recent developments in the mines have been highly satisfactory and the outlook for profitable and continued production has never been better. Circumstances make Tonopah the most prosperous mining district in the country today; indeed, it is no exaggeration to say that for the moment it is *the* most prosperous community in the United States. The recent strike was costly to the companies, the employees, the community, and to the State of Nevada. It emphasizes again the need for deliberation and fairness on all sides.

Financial and Economic Engineering

That skillful engineering can be applied outside the domain of mechanics has been demonstrated by the ingenuity and purpose displayed by Mr. Henry Ford in extricating his company from the position of financial insecurity that resulted from the general industrial depression prevailing during the early months of the year. Obligations to be met between January 1 and April 18 totaled \$58,000,000; cash in hand amounted to \$20,000,000. How was the remainder to be obtained? The story forms an interesting page of American industrial history; it may be garnered from an interview that recently appeared in the 'Detroit News'. In January, the Ford plants were closed; the Government was owed \$55,000,000 for taxes; notes for nearly \$30,000,000 would soon

be due. The demand for cars was at a low ebb; stocks were high, both in the factory and throughout the country. Wall Street, confident that Mr. Ford could not weather the crisis without aid from the bankers, proffered assistance, for a consideration. Loans were suggested. Only one banker succeeded in obtaining a personal interview for this purpose; but he was overconfident that Mr. Ford was dependent on help from the outside; the banker was dictatorial, in spite of the manufacturer's assurance that he need not borrow. The interview was terminated abruptly; "I handed him his hat," says Mr. Ford. Within twenty minutes Wall Street discovered that no help was needed. The Ford employees were called back to work; within six weeks the plant was again in full operation; 3000 cars were produced in January, 35,000 in February, 60,000 in March, 90,000 in April, 110,000 in May, 116,000 in June. On July 12, 4461 cars were manufactured; the output for the whole of last month exceeded all records; and yet production was below demand. In attempting a feat that, as the 'New York Times' says, will go down in the annals of financial history as one of the most remarkable achievements of post-war liquidation, Mr. Ford realized that the problem could be solved by liquidation and economy. He ceased to buy. He then turned all his stock in hand into cash, he eliminated what was unproductive, and forced his enterprise, for a time, to live upon itself. The first obligation to be met was the payment of a bonus to employees for services during 1920, which absorbed \$7,000,000. Attention was next turned to liquidation. In the company's contracts with dealers it was agreed that a certain quota of cars should, if circumstances demanded, be taken each year, according to the size of the district. Cars were then sent to those that wanted them, as well as to those that did not want them; agents were told of their legal obligation, and of their indebtedness to the Ford company. Future prosperity involved immediate co-operation. The plan succeeded; 57,000 cars were sold in January, 63,000 in February, 87,000 in March, and 100,000 in April. Between January 1 and April 15, stock valued at \$24,700,000 was turned into cash; foreign collections amounted to \$3,000,000; sales of by-products netted \$3,700,000; Liberty bond sales brought \$7,900,000. A vast amount of money was tied up because of delays in the transit of goods; this condition was remedied, with the result that \$28,000,000 was released. Economies were effected in the plant; the average daily output of about 4000 cars is now obtained with 15,000 fewer men than formerly. The \$6 minimum wage has been retained, but foremen have been set to work, tasks have been 'doubled up', and adjustments have been made that aided in the consummation of a plan that, for its very boldness, merited the success which resulted. Thus, by April 1, Mr. Ford had \$87,000,000 in hand to meet \$58,000,000 in obligations, all of which were paid well in advance. From such an account we may infer that engineering can be applied to organization and finance, to the discomfiture of the bankers and for the conservation of industry.

Indexing Current Technical Literature

The Editor:

Sir—Readers of your paper who regularly study its columns in order that they may keep abreast of the wave of current thought and practices in mining and metallurgy, will, I am sure, share with me the endorsement of your leading editorial of August 6. You have not wasted words, for in every paragraph is some constructive thought, which, if acted upon, should result in something tangible and worth while.

For twenty-five years I have been a regular subscriber to the leading technical magazines relating to our professional work; the volumes are bound in distinctive colored binding and constitute a large part of my technical library. I also have the several indexes mentioned in your editorial, and, after diligent search, have found them useful. The index to current literature presented in the monthly of the Institute is one of the best things in what is otherwise a superfluous addition to the A. I. M. E. voluminous publications; the topic headings are acceptable, although some of the subdivisions are too comprehensive for my needs, but I find them of great value. It is perhaps unfortunate that so many other societies and engineering magazines should attempt the same task, more or less incompetently. I cannot think that it is the prerogative of any individual or concern to control this field, but believe if the American Institute of Mining and Metallurgical Engineers is conceded to be our representative society in the United States it might properly sponsor your suggestion and carry it out with profit to itself and great benefit to the profession. If it is to be attempted, it should be well done.

Before proceeding further I wish to pay tribute to the 'Table of Contents', always found prefacing your editorial columns. This I have found extremely helpful, and after reading the 'Press', this page is 'clipped', the résumé of articles in which I am particularly interested is pasted on a card and placed in my ready-reference files. I have my own elaboration of a decimal index, and on turning to a card I immediately have before me a synopsis of the article, often sufficient to refresh my memory on the essential facts. I have but two suggestions to make, and hope you will see fit to incorporate them in future issues.

1. That you indicate by an asterisk the articles that are illustrated and

2. That, following the abstract, you add the name of your paper and the volume, as, for example, "M. & S. P., Vol. 123, page 180".

I agree with you, Sir, that an index of titles only is of little value; the caption is frequently misleading, and even though appropriate gives no clue as to the manner in which the subject is presented. I know whereof I speak, for in the discharge of my professorial duties I endeavor to keep in touch with the latest thought on the subject about which I am to lecture. Every day of the academic year I consult my index and have wasted much time turning to volume and page only to find perhaps half a dozen lines or so on the subject.

It is highly desirable that all sources of information be scanned and culled, for mining is practised beyond the Rockies, and there are men with powers of observation, inference, and expression beyond the borders of the Americas. On the subject of petrodynamics and surface subsidence, for example, while excellent work has been done by Dr. F. W. McNair of Michigan and Dr. H. H. Stock of Illinois, the French engineers have prepared and presented a wealth of information in government reports, and the Department of Mines in South Africa and Australia are far in advance of our own committee of the Institute on this important matter.

Cross-indexing may be carried to such an extreme that its purpose is defeated; however, in this detail there is much room for improvement. My pet hobby for years has been the study of the outcrop. I have never seen an index of technical literature that calls attention to this important subdivision of geologic knowledge. Abstracts of the U. S. Geological Survey reports, relating to the surface signs of ore deposits, excerpts from other papers and periodicals properly summarized and catalogued should be of great service to any student of the subject.

Platitudinous compliment of your plea avails nothing without action. I shall be glad to collaborate with you or any other competent body in the preparation of an index to current technical literature by assuming responsibility for the compilation in synoptic form of data relating to a particular phase of mining work. Example is better than precept. Next, please!

FRANK H. PROBERT,
Dean, College of Mining,
University of California.

Berkeley, August 10.

[This letter shows a splendid spirit of co-operation and we are delighted to publish it. We would suggest that Professor Probert make a start in systematic indexing by making 'Outcrops' his special subject. The attention of the Institute is invited to his offer. His suggestions for

the improvement of our own 'Table of Contents' are welcomed and accepted. We used to do exactly what he suggests, but stopped the practice, thinking it was not appreciated. We resume herewith. We shall be glad to hear from others on this subject of 'Indexing'.—EDITOR.]

Chloride Volatilization Process

The Editor:

Sir—The article on 'Chloride Volatilization Process' and your editorial note on the same subject appearing in your publication of July 30, 1921, are quite interesting to me.

I note that, at the U. S. Bureau of Mines Experiment Station, use is being made of water-vapor. This subject was disclosed by me in an article appearing in your issue of January 17, 1920. I have covered the use of water-vapor in conjunction with chloridizing volatilization by an application for patent, which has been pending for many months.

The rapidity of the expulsion of the chloridizer was disclosed by a chart in my article. The plant that I designed, erected, and tried during the latter part of 1920 and the early part of this year was designed so that the chloridizer could be added at any desired point between the point of feeding and the point of discharge, because experiments on the ore in muffles had shown that the chloridizer was expelled before appreciable quantities of the silver could be volatilized. I have covered this method also by means of a patent application.

Contrary to the impression conveyed by both the article and your editorial note, which is to the effect that the Cottrell system is the only system for recovering the fume, I have obtained practically complete recoveries of chloride fumes by means of bags and by means of both laboratory and large-sized scrubbing-towers. This is better work than, so I am advised, the Cottrell system will do. I wish to call attention to the statements relative to this subject appearing in my previous article. I have covered the use of limestone-filled scrubbing-towers in chloridizing volatilization processes by means of a patent application filed many months ago.

I do not agree with your editorial statement to the effect that most of Mr. Croasdale's suggestions and conclusions have been favored by adoption at the hands of later sponsors. Mr. Croasdale certainly deserves credit for the principle of applying chloridizing volatilization for recovering metals; but that is only as far as his suggestions could have been followed by me had I known of them when I started work on chloridizing volatilization. I did not learn of Mr. Croasdale's work nor of the work of others until some months after I had started work on chloridizing volatilization. I do not use any of the methods suggested by Mr. Croasdale—the principle of chloridizing volatilization excepted. In this respect I again wish to call attention to my previous article.

Revolving furnaces are not the best furnaces for chloridizing volatilization. I erected a stack furnace in combination with a short revolving furnace. The short

revolving furnace was a convenient continuous-discharge device and it would permit a longer treatment than could be obtained by the stack furnace alone, should such longer treatment be required. This furnace produced better results than those obtained by laboratory methods. The extraction was obtained in less than nine minutes and probably less than one minute. The temperature of the gases leaving the furnace was about 300°F. and they could be drawn off at a lower temperature; therefore the furnace would consume less fuel than a revolving furnace. The stack-furnace trial proves, on a large scale, the advantage of rapid heating, which method I disclosed in my previous article. Recent action on a patent application covering rapid heating indicates that a strong patent will be allowed.

Your editorial note was not generous toward my work.

San Francisco, August 2.

HARAI R. LAYNG.

[We accept Mr. Layng's correction and admit that his researches might well have been mentioned by the Bureau of Mines' engineers in the article to which he refers. We apologize for our remissness in not counteracting this omission by drawing attention to his work in our editorial columns. We wish Mr. Layng success with the volatilization process, as well as with the Patent Office.—EDITOR.]

Revision of the Mining Law

The Editor:

Sir—Criticism being desired of the proposed new mining laws, as revised by Winehell and others. From the proposed change of locating by legal subdivisions, it appears to be the desire and intent to kill off what little incentive there still remains for the prospector, who is always a poor man, to get out and find new mines or mineral areas. No better method can be found.

It is beyond the possibilities of the prospector, like those who have heretofore discovered nearly all of our mines, to comply with the new requirements. Those who know our mineral regions are well aware that outside of new veins, or rather new ore-shoots on known veins, in the older camps, we have but small chance of making new discoveries, only as we get into present unknown areas of well-known mining districts. In these, 90% of them is pretty certain to be found at long distances from surveyed lands. The discoverer of new mines must employ the services of a civil engineer, which may often run into absolutely prohibitive costs to the prospector. At this stage of the game he will find it practically impossible to get financial assistance.

Our present law has worked no hardships on anyone. Why the desire to change? Is it intended, as some of our learned engineers lately contend, that new prospecting must be done by the trained geologist and engineers, with picked practical men under them, and combing geologically favorable areas? Then this proposed change will accomplish the object, as only such a corps of men under the hire of the largest mining companies can stand such

expense. Look at Alaska, rich in minerals; it has lost one half of its white population during the last decade, largely owing to the governmental red tape and Coal Leasing bill—three leases taken out since its inauguration! What about fractional claims, left in old surveyed mining districts, under the proposed change?

All of our Western States were only developed by the liberal mining and agricultural land laws and their interpretations. If the possibility of large capital acquiring large areas by fraud is avoided, their continuance is to the benefit of all. If it is insisted that future locations must comply with the legal subdivisions, then let Uncle Sam, or the State in which situated, do it for the prospector. The State is the largest beneficiary.

It is not right or fair to compel the prospector to perfect his location by also filing his location, by legal subdivisions, with the nearest United States Land Office. His records always have rightly been with the County Recorder, where he can secure a proper abstract at any time.

It is probably desirable that the nearest Land Office have this record, but why not let the County Recorder send a copy of same to the Land Office? He receives a good salary; why not help him earn it? There are always many seeking the office. But do not further discourage the poor prospector (the only one who finds new mines) by adding additional red tape and expense to his present difficulties. He is nearly extinct now!

A vast improvement can be made over the present or proposed new laws as to the marking of the boundaries of the claims. The Mexican system beats ours. This requires that there shall be a substantial monument of stone or rock and mortar, two feet square and as high (under their metric system, a trifle less) erected at each corner of each claim or group of claims, and then around the outside boundary of each. The monuments must be so placed, of such size and material, in such a position, owing to the topography of the country, that from each monument the one in front and the one behind on the line can be seen, that is, there are always three monuments discernible.

To the above requirement should be added the compulsory one of cutting in the stone, or in the mortar when soft, the patented numbers of the claim or group in figures. This is the policy that I pursued in monumenting claims in Mexico. These monuments must always be kept in place; it is then easy for anyone to ascertain exactly where the lines are, and no expensive surveying work, which again discourages the prospector.

As our Supreme Court has decided that the monuments upon the ground, rather than the written patent, govern, this is of the utmost importance; we ought to have permanent and easily found stone monuments. To those familiar with the old camps, it is a well-known fact that the present system, discretionary with the U. S. Mineral Surveyor, is a farce. In the great majority of cases a wooden post is erected, with the number of the patent cut into it, and erected only at the four corners. Cattle may rub this down, the storms and snowslides may carry it away, or

sometimes a lazy man takes it and cuts it up for fire-wood. But the fact is that they are very often gone. This requires an examination of the records and the employment of a competent surveyor, which again discourages the prospector, who cannot always afford it. If a claim is worth patenting, let it be done right, make it permanent, with stone monuments, ensuring permanence. By adopting vertical planes, parallel with the other lines, we do away with all apex litigation and the geological experts, who combine with the attorneys to rob those who do find a valuable mine. Are not most of our laws made for the benefit of the attorneys as a class? About 90% of our legislators are attorneys.

G. L. SHELDON.

Denver, Colorado, July 31.

[We do not agree at all, with the imputation of selfish motives to the mining engineers who helped in the revision of the mining law, however much we may sympathize with the prospectors' lament. The imputation of motives is a poor argument. It recoils. With much of the rest of this letter we agree.—EDITOR.]

The Editor:

Sir—In the revision of the mining laws, Alaska may need something different from the laws covering the States.

I made three trips to Alaska, and spent over seven years in the Klondike and Alaska, prospecting, mining, chopping wood for the mines, cutting and rafting wood and logs, working as a day-laborer in the mines and woods. The first trip was with the big stampede in 1898. In 1900 I went from Dawson to Nome in a row-boat, down the Yukon river and along the coast of Bering Sea. At that time there were a number of transportation and trading companies operating large fleets of steamboats on the Yukon. And along the river, wherever there was a good landing for steamboats, and wherever there was a chance, placer diggings would be found. Trading-post sites covered the best part of the water-front.

At one place on the Bering coast 100 or more tents (all vacant) were set up by one transportation and trading company to hold town-lots; I was told that this same company held 3000 placer locations.

In 1910 I stampeded to a strike on the Iditarod; went down the Yukon on a steamboat; but was sorry I did not go in my own row-boat. On arrival at Whitehorse, I found navigation open to Dawson, and a few steamboats operating. The town was crowded with travelers for down-river points, the dock was crowded with freight, and freight was stored at sidings for miles out. There were a dozen or more steamboats in the shipyard, but none in commission. The company claimed it did not pay to operate them. Travelers had to await their turn in getting passage down the river. Some outfits probably lost a season's work by not getting their machinery in time.

On the lower river there were only two transportation companies operating. One was a consolidation of a num-

ber of companies, and had several good boats in use; the other, the old-timer, had only two small boats in commission, out of a fine large fleet. This is the company that made a specialty of grabbing steamboat-landings, town-sites, and placer claims. They went broke, but still they can't see where they were wrong, as, judging from the tone of the proposed mining law, they still advocate staking by power of attorney and large holdings of mineral land. It is a foolish and short-sighted policy. What use has a transportation and trading company for boats and stores if they keep the people out of the country by grabbing the placer mines? They killed the goose that laid the golden eggs. It was their business to transport the miner and to supply his needs from their stores in exchange for the miner's gold. The transportation and trading companies are the very ones who should want small placer claims, and no power of attorney. Thus there would be more claims and more claim-owners, more gold mined, and more passenger and freight business.

If placer claims were limited to 500 ft. square and no power of attorney given, instead of 3000 claims owned by one company, and only a few men working them, there would have been 8000 claims and as many claim-owners. It seems to be the fault of the company's agent or advisors, who are on or visit the ground. They probably lose their heads at the sight of a good placer clean-up, and by listening to glowing reports of rich strikes. What more do they need than to control the transportation and supply business? Let the individual miner get the gold; the transportation and trading will eventually get more than their share.

In 1910, on my last return from Alaska, I wrote a letter describing conditions there. It was published in the Seattle 'Post-Intelligencer' of November 11, 1920. I stated that Alaska needs a new mining code. The locating of mining claims by agent or power of attorney is a great injustice to the prospectors and people of Alaska. They have a very small chance to stake a claim, under the present law; an entire district can be staked by one person as agent for people who have never seen Alaska. A prospector who fails to make a discovery has a slim chance to get in on a stampede, no matter how near he may be to it. When a new district is found, parties start out with their pencils and locate the country for a hundred miles or more. Some creeks have been staked three times by different parties, each giving the creek a different name, and seldom any one of the locators stays to prospect. They wait, and if some stray prospector finds pay, they show up.

At the Klondike, in the Yukon, it was shown that it is not necessary to have large claims, or to stake by power of attorney, in order to get capital to invest in a placer camp. The first years of a placer camp in Alaska are a prospector's proposition, and many a one has made a home-stake of from \$5000 to \$10,000. There may be as large a deposit of placer gold in Alaska as was found in the Klondike, but under the present system or laws there can never be another Klondike in U. S. territory. A few

persons could control the entire district. The large claims on Otter creek in the Iditarod district are let in 300-ft. lays, and the lay-men must operate with heavy machinery. Before the Klondike strike, 500-ft. claims seemed to be the rule on the Yukon in Alaska.

Probably 25 persons control the entire pay-streak in the Iditarod district. If claims were 500 ft. square and each locator staked his own claim there would be 3000 claims and claim-owners on the pay-streak. The more claims and the more claim-owners there are, the more chances an operator has to buy or lease a claim, and the more business for the merchant and transportation companies.

A tax that is so obnoxious, unjust, hard, and expensive to collect as the Alaskan road-tax, should be changed to a miner's license; at one-half the price it would bring more revenue; and those who own the mines would help pay the taxes. As it is now, a man may own the best mine in Alaska and live outside or be exempt on account of age limit or physical condition, and a man working at the mine for so much per day if just under the age-limit must pay road-tax.

Let no person stake or own a claim or an interest in a mining claim who has not first secured a miner's license. The license should include the right to cut cabin logs and wood for his own use, hunting, and fishing in open seasons. There should be a license or registering fee collected from aliens and others, granting them the right to get logs for cabins, and fire-wood, also to permit hunting and fishing.

All placer claims should be the same size, 500 ft. square, no side-line to be more than 500 ft. long. All creek claims should be numbered, side or bench claims to be named. Discovery claim could be staked similar to quartz locations, the location notice to be posted at the discovery or location monument, and should read so many feet up or down stream to centre-end post, and so many feet away from centre-end posts to corner posts, with the number or name of claim, date of location, signed by the locator. All claims should be staked by not less than six stakes or monuments. The centre-end markings shall be the base-line, or supposed centre of the pay-streak or lode, the corner stakes to be placed at supposed right angles to the centre-end posts and marked the N.E., N.W., S.E., S.W. corner, with number or name of claim, and the name of the locator. The side or bench claims should be described as adjoining or lying about so many feet to the right or left limit of creek claim No. —. By numbering the creek claims one can judge the distance to any particular claim.

Don't try to specify the amount of gold a locator must find before locating or recording a claim; it is useless and will cause no end of trouble. The only place it could do any good would be in locating a discovery in a new district. It would put a check on the pencil locator; a clause covering that might help the legitimate prospector.

The discoverers of a new district, from one to three persons in the party, should be allowed four claims each:

two creek and two bench claims, on all streams large or small; all other stakers should be allowed two claims each, one creek and one bench claim. The bench claim need not be staked opposite the creek claim; the creek claim to have prior right over the side claim. If the locator of a creek claim thinks he has not enough room to operate his claim, he has a chance to stake a side claim adjoining his creek claim.

To provide room for the dumping or storing of tailing; this could be taken care of by condemnation proceedings and payment of damage. If the ground is low-grade or barren, the damage would be little or nothing. In every district you will find dogs-in-the-manger; so it is well to be prepared to handle them.

By staking claims with six or more stakes almost anybody can survey them; and when looking for a certain claim, if they find a stake with name and bearings, they will know where to look for the others.

By compelling every locator to be on the ground and to stake or help to stake his own claim, it will give more people in the country a chance to get a claim, and more people would stay to develop the ground. If the staker should miss staking the pay-streak he is no worse off than those who arrived there too late to get a claim.

After a locator has prospected his claim and finds it would not pay him to work it, let him relinquish it for a fee, and stake another. He can well afford the fee, as he had a chance at the ground. The fee may be graduated as to the length of time he has held the ground; a quick release within three to six months after locating should command a larger fee than where a claim has been held a year or more. The release will help the old-timer who has used all his rights of locating in the district and can't stake another claim until he makes a relinquishment, and it can be a worked-out claim; the relinquishment should not include those who have sold their claims, until five years after the first location in the district.

It should be unlawful to blanket any mineral land, that is, to stake a claim, when the locator knows he can't legally record it, and is covering the ground for others, who come later, in order that he may get a fee or an interest in the same. A blind location should be null and void, that is, the secreting of a notice of location on the ground and not putting up any noticeable markers, as is done on the desert, by placing a location notice in a can and dropping it on the ground and putting a rock or two upon it. If a prospector finds something of value, they show up and claim prior location.

It may be well not to allow any fraction of a year, the annual assessment work to date from date of location; all assessment work to be of a kind that will develop or prospect the claim; when performed, a notice to that effect should be posted on the claim. The first year's work could be light, where a suitable habitation must be constructed. The building of a cabin and the cutting of wood to apply on assessment work or mining claims in the Klondike proved a failure, as the wood could be sold, and often the cabin was disposed of or was not habitable. The law was changed to a 30-ft. shaft, or its equivalent.

There should be no cash payment in lieu of assessment work, as it will not benefit the prospector, who often is on the ground and needs the work.

The granting of a mining concession in a new camp proved to be a failure in the Klondike; Alaska has the same thing in associated claims. Grouping and consolidating can be done after the claims are located, by purchase or the owners consolidating.

Conditions in the Iditarod camp in 1910 convinced many that there is need for better mining laws, and the regulation of transportation to and in the interior of Alaska. A camp within two weeks travel of Seattle, by the lower river route, did not get its third mail for the open season until September 20, and first-class passengers were 42 days on the way from Iditarod to Seattle.

It might be well to increase the size of quartz claims to 1500 ft. square, and not to allow the claimant to follow any mineral beyond the boundaries. They could be staked 100 ft. on one side of the vein, and remainder on the side of the dip of vein, and that would probably cover the vein as far as the owner cared to work it. All mineral claims should be staked, with end or centre-end posts, or markings, as they are supposed to lie on the centre of the pay-streak or strike of vein.

The notice of location should be posted on a monument called the location post or monument. Cut out the discovery monument, as often there is nothing in sight. The notice should read so many feet, for example, upstream or in a northerly direction to a post, the upstream or north-end centre-post if in the centre, and so many feet down-stream or in a southerly direction to end-posts, and number of feet each side of end-posts to the corner-posts or markings. Then all the lines will close when correctly surveyed.

The railroad from Cook's inlet to the Tanana valley will regulate to a certain extent transportation in the interior. I believe a good narrow-gauge system would be more suitable for Alaska, as branch or spur-lines could be built to many of the interior districts. I believe a light narrow-gauge railroad can be built, operated, and maintained cheaper than wagon-roads, which can be used in the summer-time.

W. K. WHITMORE.

Mojave, California, July 20.

The Editor:

Sir—I have read the draft of the revision of the mining law in your issue of June 18. Some parts are all right, but most of it is wrong. It should not become a law, because the capitalists would soon own all the mineral land and the prospector and mine-owner would have to quit. It's as bad as railroad-land grant. Mineral land should have the same protection as agricultural land and all mining claims should be recorded in the U. S. Land Office. That would starve out some of those lawyers and law-breakers. They are the principal cause of the falling off of the prospectors, who are getting tired of being robbed and are quitting. The present Mining Code suits me but it needs a penalty attached to it for

being over-ridden by air-castle locators and title-clouders who are nothing but tools for the lawyers.

During my thirty-two years as a prospector and mine-owner I have known but three cases that went through the courts where the rightful discoverer of a mine got a square deal and that was by means of a Supreme Court decision. I have not known one case of a homesteader that was right but got a square deal. My way of revising the Mining Code is:

1. Tax every mining claim \$100 every year instead of assessment work, to be put in a separate fund to be used to develop other mines.

2. Any party staking off mining claims without making a discovery and doing ten feet of a shaft pay a fine of \$100 or one year in the 'pen'.

3. That any party staking off more than one claim on any one lead pay a fine or imprisonment as above.

4. That any difficulties arising over mineral on unpatented land be strictly an affair for the U. S. government to settle, and outside the jurisdiction of the court of the county in which it is situated. Then and not until then will the mining industry have the encouragement and protection it so well deserves.

F. J. KIRBY.

Etna Mills, California, July 27.

The Editor:

Sir—On noticing in a previous issue of your publication an article on the subject of new mining legislation being prepared by a committee appointed by the U. S. Bureau of Mines, I awaited with interest the publication of the proposed modification of the law.

Since reading the text of the proposed revision as published, I am compelled to believe that, from the passage of the Bill, the prospector and individual miner will cease to exist except perhaps as hirelings for some wealthy mining operator or corporation, and that, while the intent of the Bill is ostensibly to aid and promote mining and prospecting for useful minerals and metals, it is framed so that it will be merely an aid to the omnipresent land-grabber.

Mr. Beardsley's article in your issue of July 30 has much of good common sense in it; and there is, to my mind, no doubt at all, after reading the language of the Bill, that a prospector would have to be accompanied by a geologist, a lawyer, and a surveyor in order to protect his rights to a discovery. Then, too, after he had thus protected them, in five years he would be at the mercy of the financier if he desired to protect his claims beyond that period. True, some will say that if a prospector cannot develop his prospect and get it going in five years it is problematical if he ever could; but, admitting this point, the prospector is certainly entitled to a portion at least of the fruits of his discovery. The Bill, as written, would certainly leave him a shining mark for that class of 'sharpshooters' who infest the mining regions looking for 'cripples'.

We have sufficient examples of the evils of 'location without discovery' in the numerous mining (?) ventures

incorporated in certain localities which are based on locations made without discovery and which, after a brief period in which they are manipulated by unscrupulous stockbrokers to the disadvantage of a portion of the credulous and speculatively inclined public, gradually drop to 1 cent, bid, and then disappear from the stock-exchange list.

As a personal experience I might cite an instance that occurred a number of years ago when, after following certain of the Nevada mines for a number of months through the articles appearing in the daily press, I decided that a certain one of them was due to advance, and prepared to share the profit. On the way to the Exchange I met a certain canny and honest Scotchman, who is a mining engineer of the old school and who, fortunately, had but the day before returned from the vicinity of the 'mine' in question. Greetings were exchanged and, as the 18th Amendment had not then been passed, we adjourned to a near-by refectory and the following conversation took place:

Q. "M—— what do you know about the K—— property?"

A. "You have no interest in it, have you?"

Q. "No, but what is the matter with it, why does not the stock advance?"

A. "Well, I'll tell you. That mine is one of a string that I keep track of for some people down here who are speculating. There isn't a pound of ore in sight in it anywhere, and I see no reason to suppose there ever will be. The formation is not right."

This was, of course, enough to keep me from carrying out my intention to buy some of the stock for a rise. A few months later, however, happening to meet the same Scotch engineer at the same place, and having looked over the market quotations for mining stocks but a few moments before, the first question was repeated, and the reply was:

A. "Let's see, you asked me something about that once before didn't you, and you told me you had no interest in it?"

Q. "Yes, but I intended then to buy in on it."

A. "Oh, I see. Well, I would have to tell you now just what I told you then. There isn't a pound of ore in the whole damned mine and I don't see any reason to suppose there ever will be. The formation is not right. They are way off from the ore. But tell me, what price was it then?"

Q. "9 cents bid and 11 cents asked."

A. "Yes? That was a pretty good price for it. What is it now?"

Q. "Heavy sales yesterday at over 90 cents."

After which we took another drink and departed.

Beardsley is right. "Lodes do not conform to section corners. We do not want 40-acre or 160-acre tracts." We do want our "lodes or veins with all dips, spurs, and angles". We want our logical 300 ft. on each side of said lode-line and our 1500 ft. in length. We want the right to possess our 'discovery', and must protest volubly

against any attempt to make location without discovery legal.

It must be admitted that the so-called apex law has been the cause of some litigation, but it is apparent that it cannot have caused litigation to the extent that the new law will when a lode running at an angle crosses 40-acre tracts diagonally, and the adjacent lots on the dip are located by others who sink to strike the orebody and, for some reason or other, as will certainly happen, the various locators get at loggerheads.

The present locator of a claim sequesters but about 20 acres of the public domain. Under the new law he would never think of taking less than 40 acres of our rapidly diminishing open land. Near here, at present, the patents on at least four 40-acre lots of school-land which were purchased from this State at public auction early in 1920 are being held up still, owing to the location of three alleged mining claims approximately in a diagonal direction across the middle of the quarter section. In this case, therefore, in place of segregating 60 acres from the public domain, the three claims would take 160, and, if the one locating them desired to protect himself on the dip of the formation, he would have been obliged to locate, at the very least, four more similar lots.

The present law is based on a logical idea of giving the prospector title to such mineral as he discovers, in areas suitable to his means, and of protecting him in his discovery to the limit of depth below the surface to which the deposit reaches. It is based on sound judgment, good principles, and a logical recognition of the rights of discovery. Let us leave it as it is until we can give at least one real good sound practical reason why it should be altered as proposed or in some other manner. And while we are on the subject of laws, as our Chinese cook remarked a short time ago anent the passage of the Alien Poll Tax Law, "Whassa malla this countlee? Too muchee law. Alla time new law evely day. My countlee gotem same law 4000 years. Evelybody know him. Nobody but bad man blake him. Thisee countly 4000 new law evely year; nobody know him, evelybody blake him. Too muchee law alla time." And, by and large, Chinese philosophy has always been good philosophy.

Did you ever stop to consider the number of Government, State, County, and District officials that one who desires to operate a mine in this State must come into business contact with? The number of National and State Commissions that he is brought into contact with by the present laws and is in a measure responsible to? The number of comparatively unversed individuals who have apparently nothing to do but make new rules for the regulation of this industry is appalling. Many of the regulations in this State for deep mining for metals were taken bodily from Eastern regulations for the mining of coal from blanket veins at comparatively shallow depths.

We Mother Lode miners are mining for gold—the standard of value—the price of which we cannot change, because it is a standard. We are treated in many ways as is the manufacturer who only asks that all manufac-

turers in his line be compelled to obey the same rules, and then, if the rules increase his cost of production, he knows that his competitors are affected in a like manner and they simply raise prices to suit the new condition. This we miners cannot do. The additional cost of manufacturing is borne by the 'ultimate consumer' and is thus distributed widely and is not felt to any great extent. The cost of production of gold is borne by the producer alone. A raise in power-rates, for an example, may raise the price of cotton cloth a fraction of a cent per yard and net the manufacturer a small additional profit. This same raise in power-rates may put a gold mine out of commission and cause the enormous investment to lie idle and non-productive for years, and perhaps be a total loss. Take some of the larger gold-dredges as an example, working in comparatively low-grade ground. One might make a fair return on the investment with the rates for power pertaining prior to the creation of the Railroad Commission and, with the probable average consumption of 1.5 kw-hours per cubic yard of material excavated, might fail to 'break even' at the present rates for power. And so it goes.

In the desire to eliminate every risk from mining, rules and laws are being promulgated which, like the celebrated 18th Amendment, are being more honored "in the breach than in the observance". Laws that do not coincide with good sense and judgment will always be broken. Laws were not primarily intended to be made for the sole purpose of having something to break and, if we desire to remain law-abiding, we must not proceed to make a superfluity of intricate, annoying, and restraining regulations which hamper business, mining, commerce, and even personal liberty. There is a growing general feeling of pride among the masses in the fact that they are regularly breaking some law in some small way. People that were formerly known as strictly law-abiding citizens are almost boasting of their violations of the 18th Amendment, and the habit of breaking one law leads to the breaking of others, and thence to anarchy.

Let us take as an axiom the statement that in mining it is impossible to eliminate all risk, just as it is impossible to eliminate all risk in crossing Market street on foot. Everyone that lives and works must take risks every day. This does not mean that it is essential that every one take the view that "Life is a gamble and death is a joke", as one writer has put it, but, as each individual must, law or no law, take the risks that are common to his walk in life, be it trade, business, or profession, let us eliminate the vast compilation of hampering rules, rules which our forefathers got along very well without, and see if we cannot make more progress. A ship cannot very well sail at a high rate of speed to some foreign port when it is anchored, and an industry cannot advance when it is hampered by all sorts of petty rules and restrictions 'in restraint of trade'. The cook was right—"too muchee law". This being so evidently the case, let us be sure that we are right before we go ahead with the proposed amendment.

San Francisco, August 8.

G. L. HOLMES.

Silver and the Pittman Act

By Senator Key Pittman

*I appreciate the opportunity of informally addressing you on the subject of silver, because I feel that if I have any information on the subject which you have not, I should lay it before you. While I have no fear that the so-called Pittman Act will be repealed, I know that there is always a chance of hasty and improper legislation. Because of this chance all those who are interested in maintaining certain legislation should be advised of every fact and of every action relating thereto, so that they may be prepared to lend their aid at the proper time and in the proper direction.

The price of silver was fixed at a dollar because of conditions existing at the time; the Government is in honor bound to maintain that price until the quantity it sold under the Pittman Act has been restored. But, aside from this, the increased quantity of silver that the dollar price makes possible is a matter of sufficient importance to warrant the Government in maintaining this figure. Newspapers have made absurd statements in regard to the Pittman Act. They have used violent language in reference to the passage of the bill, and those articles are bound to have their effect upon persons who are guided by impressions rather than by arguments and facts. These attacks make it necessary for us to discuss frequently, in the most elementary manner, matters that should be of general knowledge.

Lord Reading, when about to leave for India recently, made a public address in which he stated that the action of the United States government in furnishing silver for India in April 1918 was one of the most powerful acts that could have been performed toward the winning of the War. He told his audience that it was essential to have silver in India and to have it immediately; and, astonishing as it might be, there was no surplus supply of silver in the world except in the Treasury of the United States. There was a surplus of gold in many places in the world, but there was not a surplus of silver except the four hundred odd millions of silver dollars lying in the Treasury of the United States as security for silver certificates that had been issued against it. The total production of silver since the beginning of any history is only about sixteen billions of dollars, this including silver that has been produced and utilized for every possible purpose. When we stop to think of the amount of silver lost and destroyed in those three or four hundred years, silver that is secreted never to be found again, just as gold is lost, we realize that the supply of silver in the world is necessarily small. It is possible that

the actual existing supply of silver in the world is less than the supply of gold.

The production of silver in the United States in 1881 was about 33,000,000 oz. Production gradually increased to and including 1907 when it reached 56,000,000 oz., an increase of 23,000,000 oz. Yet during all that period strenuous efforts, backed by capital, ability, and energy, were made to open up new bodies of silver ore. In 1908 and 1909 the production of silver in the United States fell to 52,000,000 and 54,000,000 oz., respectively, due to the panic conditions of that period, and the necessary closing down of mines by reason of lack of credit. In 1910 production rose to 57,000,000 oz., and it steadily increased to and during 1916 to 74,000,000 oz.; then it dropped, and has been dropping ever since. In 1917 production was 71,000,000 oz.; in 1919, 56,000,000 oz., which figure is estimated for 1920. It will probably be less on account of the copper situation.

The United States has been producing about one-third of the world's silver production, which has averaged about 174,000,000 oz. per annum, not a very large amount, although it might have been considered at one time a large circulating medium of that kind. We had nearly that much in circulation 20 years ago. In the last 20 years the business of the world has increased probably twenty-fold, but the production of silver has not increased even 50%. In spite of the expansion of business, requiring as it does more currency, there are thousands who still believe that metal money is unessential. We still hear the proponent of the greenback. I can understand how, prior to the War, this theory could have been supported by seductive argument; but in the face of recent history it is impossible for a person successfully to argue that paper, that fiat money, no matter how strongly it may be backed by a government, is security, or is a good pledge to be exchanged for property. When you see the money of a powerful government like Germany going down from 25 cents to 1½ cents in value; when you see a great government like Austria with its money valueless; when you even see a country like France, a victor, and another great country like Great Britain, a victor, with their paper currency depreciated by reason of a lack of confidence, then we realize that human nature is human nature, and that the only thing that the great majority of the world will trust is something that is not only good in one country, but is good for something in any country. There are at least two things which are good for something in every country in the world, no matter how cultivated or how uncivilized; these are gold and silver, and, strange as it may seem, there are many places in the world where gold will not be accepted and

*Abstracted from a report of a speech made before the New York section of the Mining & Metallurgical Society of America.

where silver is demanded. We have approximately three billions of dollars in gold in this country. This does not amount to much; it would not pay much more than our floating debt, yet those three billions of dollars in gold are over twice as much as any other three countries possess, and it gives to us a dominating power. It has the power of paying over and over again our internal debts, thus multiplying its power in effecting business transactions. In the same way the little silver that we have on hand, and the little silver that we place in our Treasury each year, although an insignificant sum in comparison with the business of our nation, possesses a power that enables us to transact business all over the world, and enables us to give priority to our business in South America, Mexico, China, and India.

Why were we particularly interested in India and its demands for silver in 1918? Because our boys were fighting, and one of the absolute essentials of the war was jute bagging. Practically all of the jute bagging came from India, and the Indian producers would not accept gold in payment for it. They were accustomed to take silver. Great Britain spent twenty years in teaching the Indians to accept a silver rupee certificate instead of a silver coin, by having places of redemption handy so that the Indians could get the coin every day if they wanted to. Great Britain had partly gained the confidence of these people and had issued four times as many paper certificates as they had silver in their vaults with which to redeem it. A bank is usually safe in carrying 15% reserve if there is no run on the bank, but there was a run on the redemption agencies. Germany knew these conditions, and sent its propagandists among these people, causing them to lose their confidence in paper money.

Then the British sought for silver. They themselves were astonished that there was little or no free silver in the world. They found that there was only one depository of silver and that was in the United States—four hundred odd millions of silver dollars. In a sense that silver did not belong to the government of the United States, but to the miners and the people who had sold the silver to the Government, and who took in exchange certificates of deposit, redeemable in silver dollars upon presentation. The producers of silver, geologists and engineers, for months prior to the passage of the Pittman bill, had realized that we were threatened with the closing down of our silver mines. They were animated by a desire to continue the production of metals. We were at that time striving to get our Treasury Department to purchase silver, and store it up for future use as subsidiary coin. It was no war measure that they then had in mind. By argument, engineers and producers established beyond doubt that, under the existing costs of mining, \$1 an ounce would be a fair price for the Government to pay for silver.

Suddenly the Indian situation developed. I was ready to leave for Chicago to address a body of engineers similar to this, when I received a telephone message from Mr. Baker, the Director of the Mint, asking me to come down to the Treasury Department. I was disinclined to break

my engagement until Leflingwell came to the phone, saying, "This is a matter of great importance, affecting the result of the War, and you must come down". I went down. Lord Reading was there, with other foreign representatives in conference with our own financial expert and the Secretary of the Treasury. The facts were laid before us. Lord Reading advised us that we hadn't even a week to delay in the matter, saying, "We have got to have this silver". The Germans on March 18 had started their great drive against the British line, which had its back against the wall. The British did not know where to get more men. A revolution in India would have followed the declaration of the non-convertibility of those certificates into silver, and then an enormous military force would have been required in India. Where were the men to come from? What would have been the result of the German drive of March 18 if that propaganda could have been consummated at the time they expected it to be? Immediately the question of a contract with Great Britain and a contract of our Government with the metal producers was discussed. It had already been demonstrated that a dollar an ounce was a reasonable price to pay for silver under the existing costs. There were only a few questions to answer. One was the price at which the metal would be sold to Great Britain, and it was agreed that this would be \$1 an ounce, net. Then we insisted that the Government should pay the American producer \$1 an ounce for his silver. The agreement was made. Great Britain was relieved before the law ever went into effect, relying upon the promises of Representatives and Senators, and upon confidence in the patriotism and the honor of Congress. There were few speeches made in Congress on the subject, for it could not be freely discussed in public. Each Senator was informed of the situation. He was told that the Government wished to sell this silver to Great Britain who would pay one dollar an ounce for it, and that the dollar would be used later in buying an ounce of silver to replace that which had been turned over to Great Britain. Various prices were discussed, \$1 an ounce being finally agreed on.

There is complaint against the Government of the United States for paying a dollar an ounce to the producer of American silver when silver can be bought in the open market at 60 cents an ounce. The United States government is not the party who is paying the producer \$1 an ounce; it is simply turning over the proceeds obtained from the British government. The transaction is not costing the taxpayer one cent. The Government took away the security from the silver certificates and sold it to Great Britain, with the understanding that for each dollar paid to the Government, a dollar would be paid to the producer for an ounce of silver. The Government has lost nothing in making this contribution to the War.

It cannot be considered for one moment that the Senators who solemnly entered into the contract with the Government, who understood what they were doing, who participated in that compromise, are ever going to dishonor themselves and their Government by attempting to

repeal that bill, solely because the Government could gain 10, 15, or 20 cents an ounce by repudiation.

Unless we are going to decide to do without silver, we must do what is reasonable to permit the industry to continue in this country. We are now down to an annual production of 56 million ounces. From 1909 to 1916 we annually coined for subsidiary coins various sums from three million up to eight million ounces. In 1917 we used 29 million ounces for subsidiary coin; in 1918, 25 million; and in 1920, 25 million. Today we are using nearly half the production of this country for subsidiary coin alone, and we must have it for that purpose. All of Europe must have it, and there is but little there now.

Note the trend of silver in Europe. Immediately after the Armistice was signed the price of silver advanced until it reached \$1.37 an ounce. That was not due to legislation nor to the Pittman Act, but to the fact that all of the European countries as well as China were at that time denuded of silver, and, still having credit and still receiving gold from the United States, they proceeded to buy silver to supply themselves with subsidiary coin that they had lost during the War. During the War they paid their Indian soldiers in silver. That silver never came to the light of day again, and never will unless the Indians are forced to sell their jewelry, in the form of bullion, to keep from starving. France was in such a condition after the War that she had to pass laws against the hiding of silver coins. Postage stamps were used for change. Stores were compelled to invent tags that they could pass out as change.

When our Government stopped giving credit to the European powers they had nothing with which to buy in the markets of the world. They had no gold that they could spare, no credit, and they could not get credit while they had no one working. They were compelled to melt and sell the silver they had purchased after the Armistice. The price of silver started to drop again, and it kept on dropping until it got down to 52 cents an ounce on March 5, 1921.

There is a tremendous demand for silver in the world today but there is nothing with which to buy it, and there may not be for a year or two. The only thing that has maintained production in this country is the fact that our Government is buying this silver. A letter here from a well-known silver-mine operator tells me that in 1919 it cost his company 83.94 cents an ounce to produce its silver; in 1920 it cost 95.58 cents an ounce. He closes by saying that if this bill is repealed, or if the price is cut down, these mines will have to close.

The Pittman Act will not be repealed. The question is how long will it be operative: 208,000,000 oz. of silver was sold under the bill; 50,000,000 oz. has already been replaced. Our country in 1920 produced 56,000,000 oz. It is estimated that by reason of the closing down of the copper mines we will produce only 30,000,000 oz. in 1921. You can estimate how long it will take to replace the remaining 158,000,000 oz. I am satisfied that this fund will last forever. I am confident that the price of silver will go above a dollar, due to the natural demand of the world.

When the world commences to get on its feet again, and commences to work and produce, which will be in the next year or two, and the price of silver goes above \$1 an ounce, then the Government will cease to buy, and that fund will remain available until some other cataclysm, or contingency, or conspiracy forces the price of silver down below a dollar in the general market of the world. Then the fund will come into action again, helping the producer of the United States, and also helping the producer of the world. This Act takes out of the market of the world one-third of all the silver produced and it, therefore, has a tendency to bring the level of the world market up to \$1 an ounce. I think the law is going to work so well that when it expires, if it ever does expire, the Government will re-enact it, probably with a broader scope. Our Government may take the silver of the world at \$1 an ounce and distribute it wherever we deem it to be to our best interest.

THE peace uses of antimony are many, states a U. S. Geological Survey bulletin, but only a few require large quantities of the metal, and although its war-time production amounted to nearly 82,000 metric tons per year, it yet remained a minor metal. Its field of uses, however, exclusive of the abnormal war demand, seems to be gradually widening. Consumption of the metal in 1919 is believed to have been somewhat larger than in pre-war years. Metallic antimony unalloyed has few industrial uses. In the form of fine powder, known as iron black, it is used for producing the appearance of polished steel on articles made of papier-mâché or pottery. For these purposes it is precipitated by the action of metallic zinc on an acid solution of antimony salts. Antimony alloys readily with most heavy metals, and the alloy is harder than the two pure metals. Most of these alloys possess the property of slight expansion on solidifying. Type metal is an alloy of antimony, lead, and tin; bab-bitt, antifriction, or bearing metal is usually an alloy of antimony, tin, and copper. Britannia metal, also known as white metal, is an alloy of antimony, tin, and copper, with some zinc, and rarely, small quantities of other metals. It is used in making cheap domestic tableware, teapots, and spoons. Antimony alloys find minor utilization in battery plates, toys, cable coverings, and siphon tops. Small quantities of antimony enter into certain brasses and aluminum alloys. Lead-antimony alloy, or hard lead, is used in making acid-resisting valves. White antimony oxide, mainly the tetraoxide (Sb_2O_4), is used for making opaque white enamel and other sanitary ware. In this use antimony oxides compete with tin oxide. Antimony oxide, mainly trioxide, is used as a coloring agent in the manufacture of glass, as it is more readily fusible than tetraoxide and does not impart opacity to the glass. Antimony oxides are also used as paint pigments. The red sulphides of antimony are used in vulcanizing and coloring red rubber and also as paint pigments. The natural antimony trisulphide, stibnite, enters into the composition of safety matches or of the compound which is put on the match box.

THE PLAZA AND CATHEDRAL OF ZIMAPAN

Mining Districts Near Zimapan, Hidalgo, Mexico

By Robert B. Brinsmade

Zimapan is a city of about 5000 people; it is situated in a small valley 6000 ft. above sea-level, and is entirely surrounded by ranges of the eastern Sierra Madre. Its population depends mainly for support on the mining and reduction of ores of lead, copper, and silver, as the available water only suffices for the irrigation of a few hundred acres, and the rainfall is too scanty for any natural agriculture beyond such desert products as the *maguety*, the *tuna* cactus, and the goat. The Zimapan mining district really includes, geologically, all the camps in Hidalgo along a lime-porphry contact extending from Actopan (Fig. 1) on the south in a north-west direction, through Cardonal, Peehuga, Bonanza, Monte, Balcones, Ortiga, and Las Cañas to the Moctezuma river, the eastern boundary of Queretaro. The nearest railway point is Ixmiquilpan, 30 miles to the south, over a poor cart-road—the northern terminus of the branch line running 54 miles north-west from Pachuca and constructed by the Honey family of Mexico City. Supplies are also brought in from Sayula station, on the Nacional railway, at 50 miles to the south-west. Unlike most cities away from the railway, Zimapan and its near-by mines have suffered little from the present revolution, but have been producing metal during most of this troublous period. The worst blow to Zimapan was when the retreating army of President Enlialio Gutierrez, in 1915, sacked some of its mining warehouses and merchants' stocks; but the smaller camps escaped less easily, for nearly every house was burnt.

by one army or another, in Cardonal, Peehuga, and Bonanza, and everything portable carried off.

GEOLOGY. The chief local sedimentary rocks are limestone and marl, which have been sharply folded by mountain-forming, and are now inclined in every direction, though commonly the strike is more or less parallel to the main gulches. These sedimentaries have been intruded by plutonic rocks—acid or intermediate in composition and taking the form of laccolites, dikes, and sills. The plutonics being usually softer than the sedimentaries are apt to form the gulch bottoms, while the latter rocks follow the crests. The intrusives are of Tertiary age; and, taken together, may be said to compose a gigantic batholith which has upheaved the Cretaceous sediments from Actopan to the north and north-west far into the State of Queretaro. Wherever the intrusives penetrated rocks favorable to deposition, the contact is marked by orebodies of lead, silver, copper, and gold, especially the first two metals.

The orebodies are generally deposited in the sediments at or near their contact with the intrusive, though they also occur along fissures as quartz veins. The former type takes the form of chimneys or lenses, and varies in type from the contact-metamorphic to the replacement, as will be seen in the description of the different districts. The ore minerals seem to vary partly with the nature of the matrix, partly with local variations in the porphyry, and partly with depth below the surface. The region is semi-arid, so that oxidized ores often extend to con-

siderable depths and secondary enrichment of silver and copper minerals is common.

THE MINES OF ACTOPAN. This camp lies on the east flank of a mountain range, paralleling the Honey railway, at Santa Rosa, a village about ten miles east of Actopan station. Its orebodies have been developed along a line-porphry contact, and comprise lenses in the limestone of oxidized lead ores, with some silver. The ores contain up to 40% lead and 1 to 2 kilogrammes of silver per ton, but the lenses are small and scarce, so the mines have been developed but little. The last activity was in 1918 when a few hundred tons of silver-lead ore was shipped to Aguascalientes by the Cia. Real del Monte, which then held the La Cruz mine under lease.

THE MINES OF CARDONAL. This camp seems to have been discovered in the 17th century, and the ruins of a dozen or more old smelters—some of which now show nothing but slag piles to indicate their former existence—which dot the plain below the mines indicate a considerable production. The mines are confined to the Cardonal range—a narrow mountain mass running north for nine miles from the town of Cardonal at its south-west extremity. The town is 12 miles east by wagon-road from Ixmiquilpan, and at 1000 ft. higher altitude; the range in its central peaks rises about 2500 ft. more, to an altitude exceeding 9000 ft. above sea-level. The prevailing sediments have a northerly strike and a sub-horizontal dip and are thin marls below and thick-bedded limestones above; they have been intruded and uplifted in the centre of the range by plutonic flows coming from the Sanetuario mountains across the valley, and a half league to the west.

The orebodies are in the blue limestone capping of the range, and the outcrops at the south end are therefore 1500 ft. below those in the central peaks, which occur at 8700 ft. In the north the lead ore is the richest in silver, in the centre it is ferruginous, and in the south it is silicious in composition. The central group of mines has produced considerable quantities of *almagre*, or iron-oxide paint; one mine, the Chilacoyata, shows an outcrop of high-grade hematite.

Nearly all the old mines of the Cardonal range were acquired about 1875 by an enterprising Mexican, Epitacio Barrera, who worked them with great energy till his death a few years ago. He repaired the old Spanish roads, drove the San Vicente adit, 700 m. long, to tap the Central group of mines, and another long adit, the Providencia, in the Northern group. He also constructed the Chalmita smelter, and white- and red-lead works, in a gulch with a small water-power plant to the north-east of the Cardonal range, and the Concepción smelter in the town of Cardonal. In 1917 the Barrera mines were taken under lease by the Cia. Real del Monte of Pachuca, and have been actively explored ever since. A new adit has been driven in the Southern group of mines, where also a new vertical shaft has been sunk for a depth of 150 m. by means of drills supplied by two Chicago Pneumatic company's air-compressors, driven by gas-oil engines. The company exercised its option, and purchased the

Barrera mines in November 1920 for \$150,000; but as yet this district may be considered in the experimental stage as far as mining on a large scale and with machinery is concerned. In fact all operations were suspended in February, for an indefinite period, on account of lack of orebodies of commercial value.

THE MINES OF LA PECHUGA AND LA BONANZA. Leaving the Cardonal range and following the mountains for 15 miles to the north, we reach La Pechuga gulch at 6600 ft. above sea-level; and by descending this gulch three miles to the north and 1000 ft. lower we come to the ancient silver-mining town of La Bonanza. In La Pechuga are the remains of three old lead-smelters, the largest of which ran as late as 1905 on ore from the La Cruz mine near-by, where small chimneys of lead-silver ore, yielding 12 to 15% lead and 600 gm. of silver, lie along a contact of porphyry and blue limestone. At La Bonanza, on the contrary, there is a strong fissure vein, which strikes east for nearly 2 km. from the north-south fault that formed the gulch bottom. The country-rock here is thin-bedded marl, striking north-east and dipping 45° north-west; the vein dips 70° north. Although the Bonanza vein is continuous and is a true fissure with a clearly defined hanging wall, its silver mineralization is sporadic, the greater part of it showing only quartz, calcite, black manganese, and iron oxides. It seems to be only where the main fissure was cut by cross-fissures that valuable orebodies were formed, and this occurred only at three places. The first is the San Judas mine at the west end, in the town of La Bonanza; then, a kilometre to the east, is the Don Martin mine at 8000 ft. altitude, and at the east end of the fissure are the Zapote mine openings in a gulch 1500 ft. lower.

The Don Martin mine is situated at the intersection of three cross-fissures with the main vein, and its workings had reached a depth of 150 m. below the outcrop when it was shut-down in 1910. Near the surface much of the sorted ore contained up to 5 kg. silver per ton, but at the bottom the ore yielded about 700 gm. Being high up on the mountain, the little water the mine made was easily removed by hand-pumps, which raised it to a 200-m. adit, 80 m. above the sump. The contrary was the case, however, with the San Judas mine, whose shaft-collar is only 20 m. above the gulch-bottom. Up to the 'seventies the San Judas water could be handled by two *malacates*, which were turned by mules to raise the cow-hide buckets; but a fissure was then struck—probably communicating with the creek above—and drowned the mine. To unwater the workings a Cornish pump was imported from England, after building a wagon-road over the mountains for 24 miles to connect with the highway at Ixmiquilpan. This pump had 7-in. cast-iron water-columns, and was supplied with steam by a Cornish cylindrical boiler which was consuming about 100 tons of pine wood per week when the mine was shut-down in 1893, owing to the collapse of the price of silver. At this time the vertical two-compartment shaft had reached a depth of 170 m., and was still showing a combined length of 20 m. of ore-shoots in the sump, which averaged

$\frac{1}{2}$ m. in width and yielded 2 kg. of silver per ton. An attempt was made to re-open the San Judas in 1908 by an American company that replaced the old machinery by two 80-hp. tubular boilers, sinking-pumps, and a steam-hoist. However, when a depth of 60 m. had been reached operations were abandoned; and, ever since, the mine has remained idle and full of water.

CAMPS TRIBUTARY DIRECTLY TO ZIMAPAN. As can be seen in Fig. 2, the mines supplying the smelters of Zimapan are within a radius of 12 km. to the north and west of the city, and may be grouped into six camps: the Monte, the Balcones, the Ortega, the Arcabuz, the Poder de Dios, and the La Cruz.

MONTE CAMP. This locality is named from the abundant *monte*, or brush, which crowns the hillsides, and is due to its situation on the north side of the range bordering the Zimapan valley, so that it constantly receives

tons per month each, the Candado mine occupied six miners and four peons, the Concepción had eight miners and six peons, and the San José had four miners and four peons.

BALCONES CAMP. This gulch contains the famous Lomo del Toro group whose outcropping lens, discovered in 1632, led to the first operation of a smelter at Zimapan and yielded, before exhaustion, 6000 tons of ore with 20 to 25% lead and 700 gm. of silver per ton. This ancient oxidized-ore stope long ago caved, and now appears on the hillside like a huge quarry. As in the Monte camp, the bottom of the gulch is here an eroded porphyry stock, whose intrusion lifted the original flat sediments into an antiferential fold; the strata now outcrop in the hills on

FIG. 1. ZIMAPAN DISTRICT

FIG. 2. MINES SUPPLYING ZIMAPAN SMELTER

moist winds from the Gulf. The ore deposits here have been formed by a porphyry stock intruded into lime beds. The former rock being the softer, has been eroded, and forms Escalera gulch, running downhill to the north; the limestone hills on each side contain the orebodies. The principal mine is the Conceordia, which supplies the bulk of the ore for the Hidalgo company's copper smelter in Zimapan. Its ore contains 1.2% copper, 800 gm. of silver, and 4 to 5% lead, with 7% of FeO, 2% of CaO, 12% of Al_2O_3 , and 32 to 38% of SiO_2 . The ore-shoot is 1 to 4 in. thick and up to 100 m. long. It is now being worked below the gulch-level with the aid of a 20-hp. gasoline-hoist, and is apparently the only true contact deposit of the camp. The others are smaller lenses, lying within fissures in the limestone, and are named San Vicente, Candado, San José, Concepción, Dolores, Rosario, and Chiquihuite. The Dolores ore-lens is 40 m. long and has been worked to 100 m. below the gulch-level, at which depth the sulphide zone is just beginning. The ore in these smaller mines when first broken is low-grade and needs careful and laborious sorting to bring it up to the shipping grade of 10% lead and 800 gm. silver for the lead smelters. For instance for a shipment of 12

each side as cliffs of thinly-bedded marl. These cliffs are cut by two series of dikes, of the same porphyry as the stock, one following a north-south and the other an east-west direction; both, especially the first, are often accompanied by orebodies. Only the apices of the orebodies, near the surface, have been oxidized; the remainder of them still remain a sulphide-complex that seems similar for all mines of this locality, and ranges in composition between the following extremes:

	1	2
Lead	2 to 5%	7 to 8%
Zinc	3 " 4%	23 " 24%
Iron	18%	25%
Silver per ton.....	1 to 4 oz.	10 to 12 oz.

The lead of these ores is not in galena but in huaseolite, which contains 48.5% lead and 25% zinc; and the zinc is not in sphalerite but in marmotite, with a zinc-iron ratio varying from 5 to 1 up to 2 to 1. Concentration tests made at Denver some years ago yielded a lead head with 45% lead and 10% zinc and a zinc head of 42 to 45% zinc and 12 to 8% iron. The zinc and iron of these heads existed in chemical combination with the lead and zinc, respectively. In the sulphide lenses the peripheral

ore seems to be richer in lead than the core, and the latter was often left intact by the ancients when they extracted the shell.

Although it is reported that 100,000 tons of these sulphide orebodies was developed below the water-level in the Lomo del Toro group before its shut-down in 1892, the greatest accessible orebodies are exposed in the Balcones group of the Zimapan Mining Co., which was promoted, some 20 years ago, by an American named Captain Knocker, with the backing of some New York kings of chicle. The Captain built a two-stack modern lead-smelter before he discovered that he had no ore to feed to it, and was sued for fraud by his backers, who finally won a decision and took over the property. In 1908 a mining engineer named Wrigley was sent to Zimapan by the new owners; by spending \$80,000 in development he exposed over 100,000 tons of zinc-lead sulphides of the aforesaid analyses. However, these sulphides were of too low a grade to produce a marketable concentrate without building an expensive mill, so because of the lack of a railway and the growing revolutionary disorders, Mr. Wrigley was recalled and the enterprise was abandoned. Since then the Zimapan company's mines have been worked intermittently by the former superintendent, who treats the ore in a small lead-smelter, the San José, that he has erected in Zimapan.

The Balcones group of mines lies to the north, down the gulch from the Lomo del Toro mine, and at a point on the east side where the gulch bottom lies 520 m. vertically below the summit of the sidewalls—almost perpendicular cliffs that were worked by the ancients, near their tops, for oxidized-lead ores. The mine office is 215 m. above the gulch bottom. A cross-cut adit, 68 m. below the office, cuts the San Rafael ore-shoot at 40 m. and the San Miguel ore-shoot at 130 m. below the outcrop; in each case the thickness is 4 m. with a length of 20 to 40 m. and a composition similar to No. 2 of the aforesaid analyses of sulphides. Both shoots lie along north-south dikes, of silicious porphyry with feldspar inclusions and disseminated pyrite, with some epidote, along the contact. A second cross-cut adit, started in the hillside at 24 m. below the first adit, encountered a cave system and its intersection with an east-west dike, which contained a secondary lens of rich oxidized ore, which yielded \$40,000 before exhaustion, of the following composition:

Lead	25 to 26 %
Zinc	2 " 3 %
Iron	8 %
Lime	4 %
Silica	15 %
Sulphur	7 to 8 %
Silver	1250 gm.

On the west side of this gulch, near its bottom, and opposite the Balcones group, lies the Carazal mine of the Hidalgo company. This mine is at an altitude low enough to exhibit the transition with depth, from lead to copper ores, that occurs in the Zimapan as in many other base-metal districts. The lenses of this mine lie also along the contact of the limestone with porphyry dikes, and

their lower portions have produced considerable quantities of ores, showing chalcopyrite, tetrahedrite, and pyrite, and yielding 3 to 6% copper and $\frac{1}{2}$ to 2 kg. of silver per ton; at present their output is small.

ORTIGA CAMP. The only productive mines here are the four belonging to the heirs of Marin Yañez, the former prefect of the Zimapan district. These mines are the mainstay of the Purisima custom lead-smelter in Zimapan, and yield 12 tons of sorted ore weekly; a force of 12 miners (double-jacks), assisted by peons for shoveling and hoisting, is maintained. The old workings, over 100 m. below the outcrop, have been tapped recently by a cross-cut adit, whose length, owing to the steepness of the gulch wall, was moderate. The shipping ore is mostly oxidized, and assays 15% lead, 700 gm. of silver, and 4 gm. of gold per ton. These mines were shut-down in 1911, and not re-opened till 1918, owing to litigation. Another mine to the north of the Yañez group had long been famed for rich specimens of stibnite; but a systematic exploration of its ore-shoot in 1915, by a Boston company, proved the stibnite to be only the shell of a lead-zinc lens; the mine was considered hopeless as a source of antimony.

ARCABUZ CAMP. This *cerro* lies only 5 km. from Zimapan and is therefore the nearest of all the tributary districts. The mines are in a series of low hills, either of limestone or porphyry, and the limestone is intruded by frequent dikes of the porphyry. The chief mine is the Sta. Gorgonia, of the Cia. Minera y Fundidora de Zimapan, which is a sub-vertical fissure vein in limestone. The vein was unpayable, owing to the smallness of the ore-shoot, till the workings had reached a depth of 100 m., where the shoot reached a length of 125 m. and a thickness of 20 to 250 cm., and yielded oxidized ore assaying 15% of lead, 600 to 900 gm. of silver, and 2 to 3 gm. of gold. It contained 17% of iron and 8% of lime, so that it was almost self-fluxing. Although five pairs of miners can break 10 to 12 tons of this ore daily, it takes 70 peons to get it to the surface from the present depth of 360 m., for it must be hoisted through three discontinuous and inclined shafts. Each shaft is operated by a separate hoist; and the ore hoisted from a lower shaft must be carried in a pack or barrow through a drift or cross-cut to reach the bottom of the next shaft above. The highest incline is served by a whim, and is 70 m. deep. The lower shafts are served by windlasses. The other mines on the Arcabuz *cerro* produce similar ore to the Sta. Gorgonia, but their ore-shoots are much shorter and thinner. Among them are the Fortuna, the San Gerónimo, the San Pascual, and the Providencia.

PODER DE DIOS CAMP. This is a low *cerro* a kilometre north of the Arcabuz camp. The principal lenses lie along the contact between porphyry and lime, and contain red oxidized ores with 10 to 14% of lead and 500 gm. of silver per ton. The deepest mine is the Poder de Dios, whose camp is 100 m. below the outcrop opening. Other mines here are the Esperanza, Candelaria, San Juan, Noel, and Mario.

LA CRUZ CAMP. This locality has produced some ore

as rich as 10 kg. of silver per ton, but is handicapped by the fact that the chief vein lies at the bottom of a guleh that carries a torrent during the rainy season and floods the mine. The shaft, when it had reached a depth of 68 m. in 1911, could not be longer kept dry, as the silver ore-shoot was too small to pay the expense of pumping. The mining machinery installation cost \$120,000, and is the only elaborate one in the district. It comprises a charecoal-gas-producer of 130 hp., which feeds a gas-engine driving an electric-generator for supplying current to an electric-hoist, a Sulzer centrifugal sinking-pump, and two Aldrich single-acting piston sinking-pumps.

THE LAS CAÑAS MINE. This locality contains only one mine, the Las Cañas, which lies on the hillside just east of the Moctezuma river, at an altitude of 1400 m., and 20 km. west of Zimapan. Its antiquity is evidenced by the remains of a village and a stone church, which cluster around the outcrop and forms a landmark in the surrounding desert. The ore differs from that of the first five of the Zimapan camps in freedom from lead and the fact that its shipping grade often reaches 20 kg. of silver per ton. The country rock is an amorphous blue limestone that has been intruded by a porphyry stock. The ore, however, does not lie on the contact, but in three parallel quartz veinlets about 5 m. apart, which strike perpendicularly into the west slope of the limestone hill and dip 70° to the north.

The ancient stopes have caved and now present a quarry face, 40 m. in height and 30 m. wide. At 45 m. below the base of this face a cross-cut adit was driven into the hill for 150 m. to reach the old workings by an American, named Poole, who re-opened this mine 20 years ago and worked it above the adit-level during three years with a force of 40 men. The venture paid well, when the veins were 10 cm. or more thick; but unfortunately, this seldom occurred; and, as an exploring winze sunk to a depth of 10 m. below the adit floor showed the veins there to be only one or two centimetres thick, Poole decided to stop work. The winze, however, was dry: it would have been better to have sunk 20 m. or so farther before abandonment, in order to demonstrate if the veins had pinched permanently, or were thinned locally, as occurs so commonly in veins in limestone.

Fire Hazards in Metal Mines

*When the use of candles was discontinued in the mine and the carbide lamp substituted, many metal-mine managers drew a sigh of relief, and considered themselves free from danger of underground fires. The occurrence of several serious mine fires during the past year should do much to disturb his equanimity and should make him inspect his mine for fire hazards. These recent fires should start him thinking about fire-proofing, fire-preventing, and fire-fighting methods. He should realize from a study of the causes and effects of these mine fires that the danger of fires in mines is ever pres-

ent; that fires start easily and unexpectedly; that fires on the surface and underground are hard to control when no arrangements have been made nor thought given to prevention or fighting; that it takes only a small fire to fill the mine with smoke and poisonous gas; that a mine fire often results in loss of life and serious losses of property; that operations are stopped sometimes for months and often for a year or more.

The endeavor to reduce costs to a minimum, coupled with the feeling of immunity from fire, has resulted at various mines in the development of dangerous fire conditions. The following have been observed:

1. Wooden head-frames.
2. Planked floors around the shaft collar or adit portal.
3. One or more frame buildings in the immediate vicinity of the collar of the shaft or adit portal, oftentimes grouped about the collar. At several mines frame buildings have been built over the shafts and adit portal.
4. Mining timbers piled in the immediate vicinity of the collar of the shaft or adit portal.
5. One or more cans of oil and gasoline standing at the collar of the shaft or adit portal.
6. One or more boxes of dynamite near the collar of the shaft or adit portal.
7. Oil, waste, newspapers, and papers from powder boxes thrown under the timbers of the inclined head-frame.
8. An accumulation of waste materials and refuse around collar of shaft or adit portal.
9. Wooden snowsheds leading to the mine portal with boxes thrown under the timbers of the head-frame.
10. Accumulation of oil, waste, and paper, in the incline timber-sets immediately below the shaft collar.
11. Pump-house and hoist underground not fire-proofed; uncovered oil, waste, and cans of lubricating oil in the immediate vicinity of the pumps and hoists.
12. Accumulation of combustible rubbish, dynamite, and mine timbers at underground stations.
13. Electrical equipment not properly insulated and not placed in fire-proof stations.
14. Underground magazines in unclean condition; boxes and papers permitted to accumulate; dynamite in working places.
15. Large carbide containers left open, partly filled with carbide.
16. Pulleys and idlers in shafts permitted to run hot.
17. No attempt made to control ventilation.
18. No fire-extinguishers or fire-hose available.
19. No self-contained oxygen-breathing apparatus.
20. No men trained in the use of the self-contained oxygen-breathing apparatus.
21. No plans made for fire fighting.
22. No disaster signals.
23. No arrangements for converting the air-lines into water-lines to fight fires.
24. No fire doors.
25. No fire-inspection in the stopes.
26. No thought given to fire-proofing the shaft collar, the shaft timbers, and the stations.

Mineral Industry of South Africa

By Owen Letcher

INTRODUCTION. For a number of reasons the present position of the mining industry in South Africa invites attention. Last year the Transvaal contributed over 50% of the gold output of the world; in the absence of the development of any new gold-field of importance the mints of the nations will have to continue to look to the Rand for the maintenance of a supply of the precious metal. Another aspect of importance is the growth of the coal export trade of the Transvaal and Natal. From an American point of view special interest attaches itself to the condition and prospects of the diamond market—the United States being the principal consumer of South African brilliants—and to the entry of American capital into the field of diamond production. Other features of the mineral activities of the sub-continent are the initial development of an iron and steel industry, the growth of the asbestos-producing industry, and the stagnation of copper and tin mining resulting from a serious decline in the prices of these metals.

GOLD. For some time past it has been evident to the most casual student of mining on the Witwatersrand that the Main Reef series has passed its zenith of prosperity. The old rich outcrop section of the Central Rand, which under the technical tutelage of Hennen and Sidney Jennings, George E. Webber, and other American engineers made the Rand famous and greatly enriched its financial sponsors in the 'nineties, has ceased to exist. The first row of deep-level mines, with which the name of John Hays Hammond will always be associated, has become almost exhausted over the greater portion of the Central section; and even in some of the others a lack of profitable ore, greatly hastened by the advance in working cost, is imminent.

The principal developments of today are taking place in the eastern annex of the old Central Rand, which lies between Benoni and the Nigel, and is known as the Far East Rand. The growth of production in this district during the last decade has been almost in direct proportion to the decline of output and development in the Central section; and at the present time the 11 producing mines of this area (the New Modderfontein, Modderfontein B, Modderfontein Deep Levels, Modderfontein Government Areas, Modderfontein East, Van Ryn Deep, Van Ryn Estate, New Kleinfontein, Geduld Proprietary, Springs, and Brakpan) are earning nearly three-quarters of the profit of the whole Rand. In addition, the New State Areas mine is forging ahead with a progressive scheme of development, and will commence production within two years. Two other promising enterprises are the West Springs and Daggafontein mines, in which the Anglo-American Corporation of South Africa is interested. Development has so far been attended by poor re-

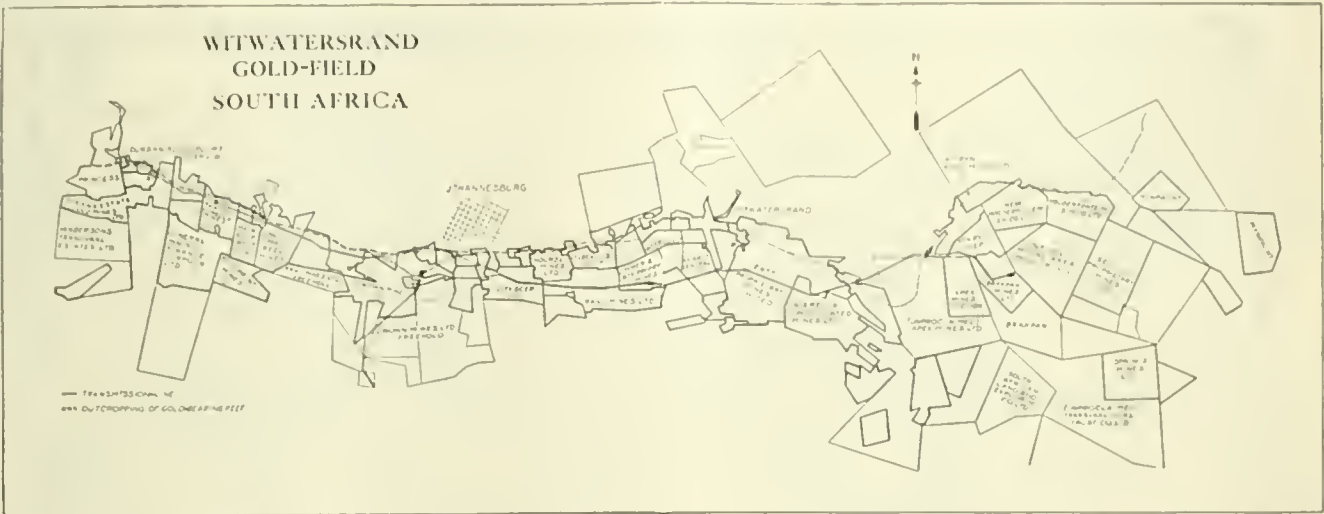

sults. The Daggafontein company has recently suspended operations for the time being. The claim-holdings of these companies, however, are so large and the development carried out has been so little that it is considered probable that the adoption of a more intensive exploratory policy will result in the finding of large blocks of profitable ground. On the Far East Rand the development exposures to date, except in the rich sub-outcrop sections of the Modderfontein mines, have not disclosed more than about 55% of pay-ore. The gold occurs in fairly well-defined shoots of indefinite latitudinal and longitudinal extent; until more driving, raising, and sinking have been carried out, the dimensions of these shoots cannot be determined accurately.

The same evidences of an early exhaustion of profitable ore have been observed in the area lying west of Roodepoort and in the vicinity of the townships of Luipaardsvlei, Witpoortje, and Krugersdorp. Years ago the French Rand, Lancaster, and Lancaster West properties ceased operations, and more recently the Princess and Durban Roodepoort have also done so. The one bright spot in the industrial firmament of the Western Rand is Randfontein. Within the past few years this group of properties, which at one time was the biggest disappointment of the Witwatersrand, was purchased from the Sir Joseph Robinson control by the Johannesburg Consolidated Investment Co., otherwise Barnato Bros. and Solomon B. Joel. Under the management of this enterprising corporation the scheme of development has been re-organized. The numerous old and inefficient shafts are being abandoned, and in their place two new deep-level vertical shafts of large capacity, which have encountered good ore in depth, are coming into use. These will supply the 600-stamp battery—the largest of its kind under one roof in the world. Good development exposures are also recorded on the Horsham-Lindum series of reefs, which overlie the Randfontein orebodies; and it appears probable that within the next year or two the Randfontein properties will earn substantial profits.

THE OUTLOOK ON THE RAND. Although there are sections that promise to maintain output and dividends under conditions less favorable than those obtaining at present, it must be admitted that the condition of affairs on the Rand is unsatisfactory. The gold-mining industry of the southern Transvaal is merely being kept off the rocks of perdition by the trade-winds of the gold premium. The average recovery for the Rand at the present day is about 6½ dwt. per ton; working costs are 26s. per ton milled, so that it is obvious that with gold back at its old standard price of £4.24773 per ounce the Witwatersrand as a whole would be an unprofitable affair. The depreciated value of the British pound in terms of dol-

lars, which determines the amount of the so-called gold premium, has proved the salvation of the low-grade mines; and it is considered that within a few years of the disappearance of the premium only two mines will be producing between Randfontein and the Van Ryn Deep, namely, the Crown Mines and the City Deep. On the present basis of working costs only the richest mines of the Far East Rand (such as the New Modderfontein,

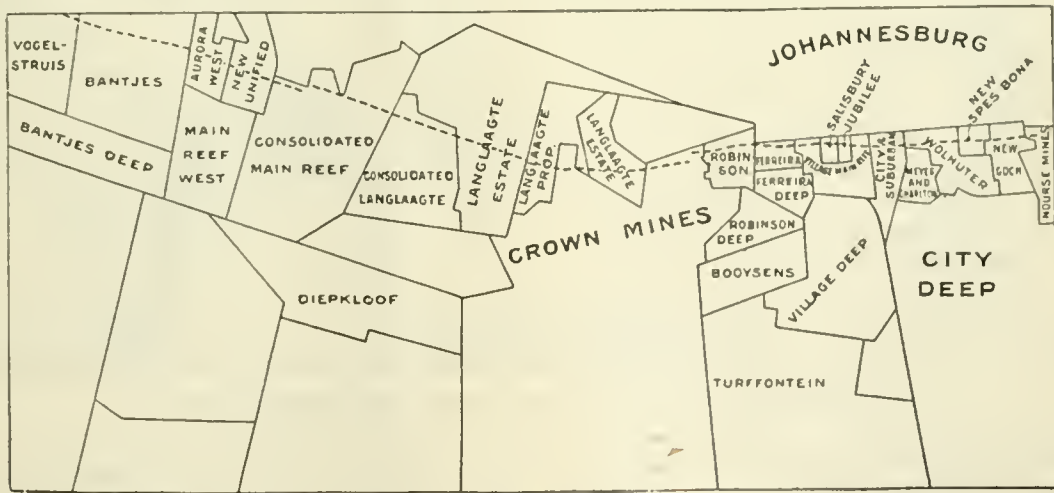

tinned increase in the cost of supplies, working expenses rose until they were 40% in advance of pre-war rates. In the middle of 1919 the selling of gold in the open market brought relief to an industry that was almost on the verge of bankruptcy. Unwarranted concessions continued to be made, until, in the early part of this year, the Labor forces attempted to bring about a big demonstration on the eve of the Parliamentary elections, and

Government Areas, Modderfontein B, Modderfontein Deep, and Van Ryn Deep) would be able to continue paying dividends.

Reduction of working costs, which means increased efficiency, is the greatest need of the Rand today. During the War the cost of supplies and wages advanced enormously; and, concurrently with the enlistment of the best class of miners for active service, large numbers of

overstepped the mark by causing a series of ill-timed strikes. Since then there has been a much-needed stiffening of policy in the councils of the Transvaal Chamber of Mines, and a campaign for efficiency is being initiated. It is interesting to note that the complex questions relating to what is termed 'selective mining' are being reconsidered; in several quarters it is contended that the Rand mines, and particularly the richer ones, should

the poorer classes of the agricultural community were attracted to the mines. At the urgent request of the Imperial government every effort was made to maintain industrial peace. Large concessions were made in respect of wages and working hours. 'Peace at any price' became the slogan of the industry.

This state of affairs was without justification: it continued after the signing of the Armistice, and it bore disastrous results. Discipline was undermined, a spirit of semi-bolshevism grew apace; and, in the face of a con-

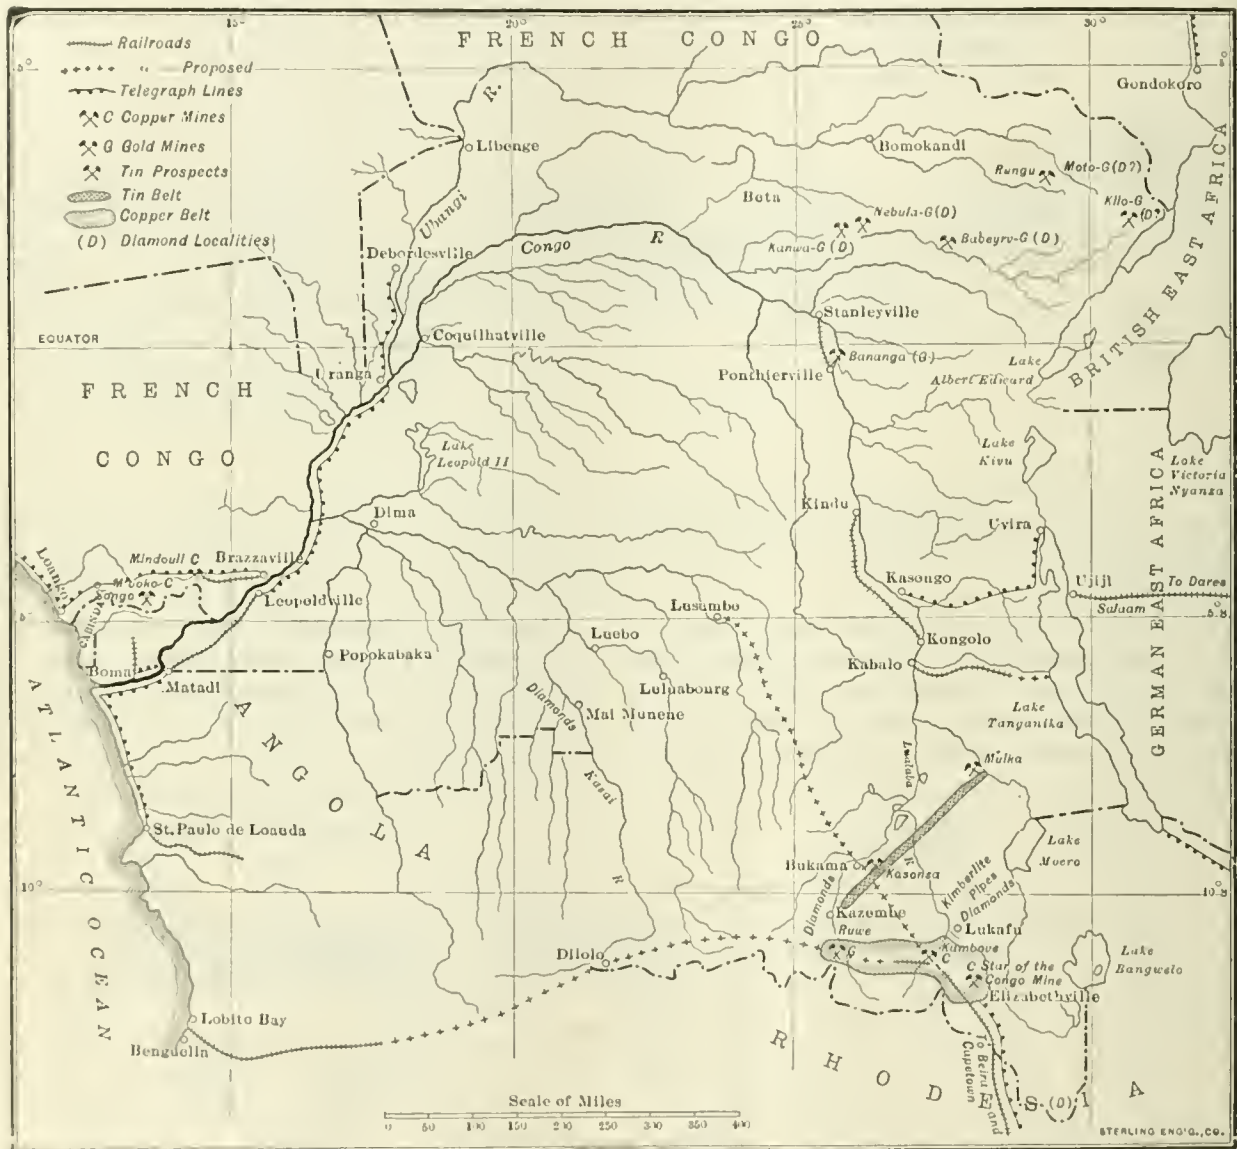

crush the richest ore they possess while the gold premium is in force, disregarding the maintenance of regular returns.

COAL. One of the outstanding features of the mining industry of South Africa has been the realization of the value of the extensive coal measures of the Union that are concentrated in the mid-eastern section of the country. Until recently the glamor of the goldfields and the glitter of diamonds appear to have blinded people to the potentiality of the coalfields, and to the value to the

country of an important basic industry. The coal measures of the country extend over the greater part of the south-eastern Transvaal, the northern section of the Orange Free State, and northern Natal. Coal is found also in close proximity to the coast in the neighborhood of St. Lucia bay, a shallow land-locked harbor in Zululand.

The coalfields of South Africa are estimated to con-

coaled at the Cape, and at Natal and Portuguese East African ports. Since the conclusion of the War the price to which coal has risen in bolshevist and semi-bolshevist Europe has tended to build up a large market for South African coal, not only in the East but even in several European countries. The Enyati, Bernicia, and Buffalo collieries in the Vryheid district of northern Natal have, for instance, secured substantial contracts

THE CONGO REGION AND OTHER PARTS OF WEST-CENTRAL AFRICA

tain not less than 60,000 million tons of saleable coal. The quality of the bulk of South African coals can hardly be described as first grade. The average calorific value probably does not exceed 12, and much of the material carries high percentage of sulphur and of ash. There are, however, large amounts in the Witbank field of the eastern Transvaal and in Natal, of coal of a quality that compares not unfavorably with Welsh coal, and that found a ready market at Delagoa Bay and Durban during the War and after the Armistice.

During the period of hostilities in Europe, and because of the closure of the Suez Canal, large numbers of ships

for supplying the French railways; coal from the Witbank district of the Transvaal has been dispatched to Scandinavian ports. A coal trade of considerable dimensions has also been built up between South African ports and South America and Egypt.

In 1915 the coal output of the Union of South Africa was worth £2,142,479 at the pit's mouth, and £3,566,621 in 1919. In 1920, 11,473,452 tons was sold for £4,506,572. The demand for Transvaal and Natal coal at South African ports during 1920 was so great that many new collieries were opened in various parts of the country by financial and mining corporations that hitherto had not

interested themselves in coal mining but had devoted capital and energies to the more speculative and attractive branches of mining concerned with gold and diamonds.

The Central Mining & Investment Corporation (otherwise Eekstein's) and the Johannesburg Consolidated Investment Co. (Barnatos) acquired options over large areas of coalbearing territory in the eastern Transvaal and northern Natal. Extensive boring operations were undertaken, and the Corner House has thereby proved the existence of a large new area on the Wolvehoek farm in the Witbank field. The Barnato interests acquired a number of collieries in Natal and the Transvaal, among which were the Natal Cambrian, Burnside, Central, Bellevue, Carlew, and Springs coal mines. So great became the public interest in coal that, a few months ago, new coal flotations were practically a daily occurrence: every other person one met in the corridors of the Johannesburg Stock Exchange had, in his waistcoat pocket, an option over a coal farm.

The increased business of the collieries, consequent on the unsatisfied demand of the bunkering and exporting trades, brought about the opening up of numerous low-grade collieries; shipment of coal from these properties has, unfortunately, led to several cases of spontaneous combustion in the holds of ships coaling at South African ports. A Government coaling commission has made recommendations with a view to minimizing the possibility of exporting bad coal.

BY-PRODUCTS AND OIL-SHALE. Little progress has been attained in the South African by-product industry. The Witbank company is manufacturing tar, and the Dundee company is erecting a large by-product plant at its Burnside colliery. The Natal Ammonium Co. has ceased operations. The Royal Dutch-Shell group has secured options over a large area of bituminous shale in the Wakkerstroom area of the Transvaal and in Natal.

DIAMONDS. The late Cecil John Rhodes is credited with having said that the second largest productive branch of the mineral industry in South Africa—that of winning and marketing gem-stones—is dependent on the vanity of woman, and, as someone else added, the depravity of man. Whether this be true or not, the essential point is that the diamond industry has, during the past year or two, proved itself to be fickle. In 1919 and 1920 it enjoyed a period of unparalleled prosperity. In 1915 the sales of South African diamonds were slightly less than £400,000; in 1919, £11,734,495; last year the aggregate value was £14,762,956. The Great War dealt a severe blow to diamond mining. The big selling syndicate had a large accumulation of stones on hand, and in 1914 the syndicate that controls the sales of diamonds from the De Beers, Premier, and Jagersfontein companies reduced operations (90% of the Union's production) to the minimum. In 1916, however, the industry began to show signs of recuperation. A renewed demand for diamonds (principally from countries whose frontiers were besieged by belligerents and whose inhabitants de-

sired investment in some form of easily transportable wealth) induced the controllers of the mines to recommence production on a large scale. The volume of the market continued to increase, and in the period of world-wide extravagance succeeding the Armistice the outputs and sales of South African diamonds rose to record figures. Prices secured for good brilliants of moderately small size advanced to as much as £15 per carat, and the world-wide demand led to the re-opening of numerous abandoned prospects in various parts of the country, and to a rush to the alluvial fields along the banks of the Vaal river. Prospecting parties scoured the veld throughout the Free State and the western portion of the Cape Colony. Discoveries of importance were made in the Postmasburg district, 140 miles to the west of Kimberley, and it is here that one or two new companies and syndicates have recently commenced washing operations.

The condition of the diamond market, which had steadily been improving for four years, reached its crest of buoyancy about May 1920. In that month the first signs of a break in prosperity became noticeable, and in response to the influence of altered conditions in the world's trade the gem-stone market began to disintegrate. The majority of the smaller syndicates collapsed, but the larger mines continued to maintain operations until early in the present year, when, shortly after the arrival of Mr. Solly Joel (the leading diamond magnate), there was a wholesale dismissal of employees and a curtailment of operations.

The depression in the diamond market led to great distress, and many mines were closed down. Although the slump in diamonds was due to general trade stagnation, it is believed that the threat of competition to the selling operations of the great diamond syndicate (made by the newly formed Consolidated Diamond Mines of South-West Africa by the Congo Diamond Fields and by the River Diggers) induced the financiers who control the sensitive market for gem-stones to announce that diamonds had become almost unsaleable.

The Consolidated Diamond Mines of South-West Africa has been floated under the auspices of the Anglo-American corporation, and controls the bulk of the alluvial areas of the South-West African Protectorate (formerly German South-West Africa). The diamondiferous alluvials of the Kasai River basin in the southwestern portion of the Congo Free State and northern Angola cover 8000 square miles, and in 1920 produced 250,000 carats. These fields, which have great productive potentialities, are controlled by the Forminiere company, in which Thomas F. Ryan holds a large interest. The fact that American capital is represented on a large scale in both the Congo and South-West African fields has given rise to a belief that a combination of these two productive areas, backed by New York millionaires, may threaten the supremacy of the diamond syndicate; one rumor is to the effect that the 'Solly' Joel is already negotiating terms with the American interests for the future disposal of the product of Africa's expanding

diamond fields. The outlook is at present obscure, but the view is held that the present entailment of output, coupled with an improvement in world-trade conditions, will lead to a revival in the market for brilliants.

OTHER MINERALS. The decline in the value of tin and copper has led to a depression in base-metal mining. In 1915 the Union's production of minerals other than gold, coal, and diamonds was £2,349,625. By 1919 it had dropped to £904,520, and last year it was worth slightly over £1,000,000.

The three leading cassiterite producers of the country (Zaaiplaats, Leeuwpoot, and Rooiberg) have recently curtailed operations considerably; in the absence of any new developments of promise, the outlook for these ventures can scarcely be considered as satisfactory. In the South-West African Protectorate some promising deposits of alluvial and lode tinstone have been developed in the vicinity of the Erongo mountain in the Karibib and Omaruru districts. The Central Mining & Investment Corporation has recently secured a substantial interest in the Kohero mine. In regard to copper mining there have been no new discoveries, and the decline in the price of metal led to the closing down of the Namaqualand and Messina mines.

Asbestos production in the Transvaal and Cape Colony is on the increase, and substantial amounts are being marketed in America. The old Pretoria silver-lead mines are being re-opened, and several argentiferous galena deposits are being exploited in various parts of the Transvaal. A new nickel mineral is being mined in the Barberton district of the eastern Transvaal.

IRON AND STEEL. Great importance attaches to the establishment of iron and steel foundries in the Union. For the past eight years the Union Steel company at Vereeniging has been using scrap-iron, and has been supplying the railways and mines with large quantities of rails and sleepers, as well as heavier castings. The Newcastle Iron & Steel is now completing the erection of a blast-furnace in northern Natal, and will produce large quantities of pig-iron in the near future. The Iron & Steel Corporation of South Africa has been floated to establish a large iron and steel industry on the Pretoria Town Lands, but has not so far secured the substantial sum of capital required to put the venture on a sound basis.

The value of the mineral production in South Africa and its mandatory annex, the South-West Protectorate, to date has been about £900,000,000, and the known resources of the Union are estimated to contain minerals of a substantially larger value than this figure. For the time being the mining industry is under a cloud and is suffering from the effects of world-wide depression and trade stagnation. It is, however, a fair presumption that, with any recovery in financial and trade conditions generally, South African mining will again forge ahead. Certainly few countries offer more attractions to capital; taxation is light and there is an abundant supply of cheap labor.

Russian Gold Exports

The attitude of the United Kingdom toward shipments of Russian gold from England to the United States, as affected by the recent decision of the British court in the gold-test case, is described in a cable from George Harvey, U. S. ambassador at London, in which he said that the London Board of Trade now takes the ground that the outcome of the test case demonstrates that no holder of Imperial Russian securities can successfully contest the Soviet claim to legal ownership of the Russian gold-reserve; and it is stated that the Bank of England will henceforth grant export licenses, on documents of title, for Soviet gold without regard to the character of the assay marks it carries.

In further elucidation of the court decision referred to, the following report from Trade Commissioner W. J. Page, of London, is of interest: A test action brought to decide whether gold rubles, forming part of the gold-reserve of the late Imperial Russian government and now brought to Great Britain by the agent of the Soviet government, were attachable in respect of obligations of former Russian governments, was decided by Mr. Justice Peterson.

The matter came up in an action by Arthur Grotjan Marshall, of Cheam, against Mary Grinbaum, of Bond Street, for a declaration that 7500 gold rubles deposited with the Bank of England for safe custody were charged in favor of the holders of 5% Russian State bonds of 1906. Had Mr. Justice Peterson decided that they were, the Soviet government would have had the right to cancel the Anglo-Russian trade agreement. Mr. Justice Peterson, however, dismissed the action with costs. Giving his judgment, he said that the defendant admitted that the rubles formed part of the gold-reserve of the Imperial Russian government, and that they were brought into this country by her as agent for the Soviet government. The plaintiff claimed that the gold-reserve of the Imperial Russian government was, by ukase dated August 1897, mortgaged to the holders of Russian notes. That contention did not seem to be well founded. The object of the ukase was to make the notes convertible. Apart from that, if any charges were created by the ukase of 1897, it was suspended in 1914 when, in view of the circumstances created by the War, the right to exchange notes for gold was suspended by another ukase.

The methods adopted by the Soviet Russian government to render its gold-reserves bearing the stamp of the old Russian government acceptable in other countries, prior to the foregoing decision, is described by a correspondent of the 'Daily Telegraph', a transcript of which reads as follows: The Stockholm mint has in the first five months of this year [1921] melted down 70 tons of Russian gold, as against 19 tons for the whole of 1920. The gold thus treated was supplied by the bolsheviks, and consisted of bullion and of ingots marked with the Russian eagle. The gold melted by the Stockholm mint is cast into blocks bearing the Swedish hall mark, which makes it acceptable in the United States and other countries.

REVIEW OF MINING

CURRENT COPPER CONSUMPTION

The industrial depression that since late last year became so pronounced is finding graphic reflection in current consumption of copper. It is close to three years since the Armistice; only on one or two occasions has a conspicuous buying movement appeared in copper. The metal recently broke through 12c. per pound, the lowest since 1915; surplus is still top-heavy and notwithstanding production has stopped, with the exception of six or eight of the smaller mines, the price shows little tendency to advance, says a writer for the 'Boston News Bureau'.

The automotive industries are now consuming at the rate of 54,000,000 lb. for 1921, against 99,300,000 lb. actually consumed in 1920. The electrical industry is 80,000,000 lb. behind last year; the telephone and telegraph 15,000,000 lb. behind. The following table shows the estimated current consumption of American copper by the leading industries of this country, including metal shipped abroad in finished form:

Consumption for:	1921	1920
Electrical manufactures	260,000,000	340,000,000
Telephones and telegraphs	85,000,000	100,000,000
Wire not included elsewhere	110,000,000	190,000,000
Automotive industries	54,000,000	99,300,000
Railway locomotives and cars	11,000,000	17,000,000
Shipbuilding	24,000,000	71,500,000
Buildings	40,000,000	53,400,000
Ammunition	14,000,000	23,400,000
Bearing metal for steam railways	10,000,000	45,000,000
Other uses	100,000,000	197,200,000
Exports of copper manufactures	61,000,000	161,000,000
Total	805,000,000	1,301,800,000

In shipbuilding, locomotive, and car-building, the consumption of copper at present is at a low ebb. But with the rolling-stock of American railroads in a sad state of repair and with an imperative demand for new equipment, it is quite probable this industry will increase its copper takings within the not distant future. The other lines of consumption will more nearly conform to the rise and fall in general business.

J. P. CHANNING AND W. A. PAINE DISCUSS COPPER OUTLOOK

Hope for a great improvement in the copper industry within six months was expressed last week by J. Parke Channing, president of the Seneca Copper Corporation, who recently visited the mines at Calumet to inspect the property. Accompanying Mr. Channing were Thomas F. Cole, director, and E. J. MacNamara, secretary. Mr. Channing asserts that a better feeling toward the coppers prevails.

"Curtailment, the only remedy that could revive the industry, is showing its effects," said Mr. Channing. From a normal output in the United States of about 100,000,000 lb. per month, the curtailment process has reduced the production to 18,000,000. The surplus is being reduced gradually, but consumers will suddenly awaken to the fact that not more than six months output is on hand. Ordinarily 400,000,000 lb. of copper is in process, from the mouth of the mine to the decks in the form of refined copper, and it is obvious that a shortage of copper is bound to come with any quickening of purchases. There may be no great increase in the volume of domestic business within six months,

but possibly by that time Europe will be in a position to take our copper, both what it needs for ordinary purposes of manufacture and for replacement. The domestic demand is slowly improving and perhaps some people are impatient over what they term slow recovery. We must realize that we cannot get as quick a reaction as in the past but it is on its way. We also must remember that the United States is self-supporting, self-contained, and can get along without foreign countries. Accordingly we will be back sooner than Europe and meantime great stocks of commodities must go abroad to help the old world rehabilitate."

William A. Paine, president of the Copper Range company, after a recent visit, said: "One must not lose faith. Copper always has been a necessity in industry and will continue to be. Copper must and will come back, stronger than ever." Mr. Paine would venture no opinion as to whether or not there will be a general resumption of mining operations this year. He commented, however, on the fact that the biggest producers of copper discontinued output to remedy the dislocation between supply and demand, and that June was practically the first month in which the effect of the mine shut-down was noticeable to any extent so far as decrease in production of refined metal is concerned; no improvement has yet been shown in demand. On the other hand, it will take at least four months, after the mines resume, to bring refinery production up to normal figures. Copper consumption, Mr. Paine believes, largely depends on the return of general prosperity. Approximately 70% of the business now being done by the rolling-mills is with the automobile industry, which goes to show the extent of the depression in other industries which normally use large amounts of copper.

NEW SHAFT-SINKING RECORD

A new world's record has been established at Eureka, Utah, for shaft-sinking by the Walter Fitch Jr. Co., shaft and mine-tunnel contractors. The Water Lily shaft, on the property of the Chief Consolidated Mining Co., was sunk 427.5 ft. in the 31-day period from July 15 to August 15, or an average of 13.8 ft. per day. The shaft has three compartments, the outside dimensions of which are 5 ft. 9 in. by 15 ft. 6 in. Two compartments will be used for hoisting ore and taking supplies into the mine, and the third for air and ventilating pipes, and as a manway. The shaft is timbered with 8 by 8 material, and the inside dimensions of each compartment are 4 ft. 4 in. by 4 ft. 6 in. Three shifts were worked, under the supervision of J. D. Matheson and H. W. Jarvis. Most of the timbering was done on the day and afternoon shifts. An average of 2.8 sets of shaft timbers were placed per day by an average of 4.8 timbermen, and this work was carried on simultaneously with the drilling and shoveling. An average of 72.5 buckets of rock per shift was hoisted. The hoisting was done in two compartments, with buckets of 17 cu. ft. capacity. The buckets were dumped by automatic dumpers, devised by the company's employees, so that the time of dumping was reduced to 15 sec. per car. It was necessary to drill 23.9 holes each round, and there were three rounds per day. An average of 15½ lb. of 35% gelatine powder was used per foot. The surface equipment consisted of two

small hoists and two compressors, while underground, standard equipment, consisting of Ingersoll-Rand Jackhammer drills, the Sullivan DB-33 drill, and the Denver Rock Clipper, was used. The first 367 ft. of the shaft passed through porphyry, which was good material for shoveling but difficult to drill, on account of stickiness. About 50 ft. of the porphyry had a tendency to 'slab' off before timber was in place. The last 60 ft. passed through what is known locally as 'white lime shale', which is a moderately hard close-grained limestone. During the 31-day period but 13 hours was lost on account of repairs and power failures. The crew employed on the work consisted of 18 machine-men, 4 to 6 timber-men, 6 top-men, 6 hoist-men, 3 shift-bosses, and a general foreman. In addition to their regular wages, the shift-bosses, machine-men, and timber-men received a bonus of \$120 each, and the hoist- and top-men, \$60 each. Sinking of the Water Lily shaft is being continued at practically the same rate as obtained during the record-breaking period. A photograph of the men who did the work is reproduced on the opposite page.

CONSOLIDATED COPPERMINES DEFAULTS PAYMENT OF INTEREST

The announcement has been made by the management of the Consolidated Coppermines Co. that it has been unable to meet the interest coupons due on August 1, and asks the indulgence of the holders until the company can be re-financed. The company has been a heavy borrower for many years, but during the War it produced; hence shareholders were generally of the opinion that the management would be able to take care of the interest account of its indebtedness without further borrowing. During the early part of the year the company offered a bonding issue to shareholders through which it expected to raise \$5,000,000 to be used in retiring all outstanding bonds and provide the means necessary to building a modern milling plant. But owing to depressed conditions it appears that the management was not successful in placing the new issue, hence it is now facing conditions which will require immediate financing to a limited extent in order to take care of its interest charges.

SOUTH AFRICAN MINERS' STRIKE AVERTED

An agreement has been reached as a result of which a strike by the South African miners has been averted, according to a Consular report. Under date of August 9, Trade Commissioner P. J. Stevenson, of Johannesburg, cabled the Bureau of Foreign and Domestic Commerce that the miners have agreed to accept a reduction of 1s.6d. per shift. This arrangement will obtain until October 1, when wages will be adjusted by quarters, the basis for the wages for any period being the cost of living for the quarter preceding. Mr. Stevenson states in his cablegram that South African business interests are well pleased with the settlement, believing that it will not merely stabilize the mining industry but will have great weight in stabilizing wages in other industries as well.

The demand for reduction in the wages paid to those working in and about the mines followed the decrease in the selling price of gold, the gold mines being the ones principally affected. At the suggestion of the Chamber of Mines a reduction of 3s. per shift was considered, amounting to a weekly reduction of 18s. The trade-union representatives claimed that the proposed reduction could not be justified. A compromise has now been effected as outlined above.

CALIFORNIA

Grass Valley.—Production at the Empire mine is again approximating \$90,000 per month. The 80-stamp mill is operating at capacity. Ore of excellent grade is reported

below the 4000-ft. level with the vein-system showing persistence as explorations extend into new territory. From present indications the Empire will finish the year as the second leading gold mine of California, surpassed only by the Carson Hill group of Calaveras county.

Randsburg.—J. M. Fox, superintendent for the California Rand Silver, Inc., reports that the ore-pocket at the 11th level is completed. On the 9th level, main shaft, shrinkage stoping is in progress, yielding good shipping ore. No. 2 shaft was sunk 17 ft., making the total depth 262 ft. The necessary excavations for mill construction have been completed and concrete work is now in progress. The balance of the steel for the four water-storage tanks has been received. These will have a combined capacity of 400,000 gal. The order has been placed for a new compressor having a capacity of 1302 cu. ft. of free air per minute. On its arrival it will be installed at the No. 2 shaft where, eventually, the main mine plant will be situated. Production of shipping ore was maintained at the rate of 10 cars per week or about 440 tons. There are now being employed from 140 to 150 men.

The Coyote company, at 70 ft. from the shaft on the 500-ft. level, has three feet of high-grade shipping ore. The management will do extensive underground development before mining any of the ore. In cross-cutting they are now advancing 24 ft. per day.

Thirty stamps are now dropping on screened ore from the old glory-hole of the Yellow Aster.

Redding.—The Washington mine near French Gulch, which has been operated by G. E. C. Rousseau for ten months, has had to shut-down owing to the shortage of water. He reports that he did well and will resume work as soon as the water-supply is replenished by winter rains.

Sonora.—The rim of an ancient gravel channel has been entered by the tunnel at the Monarch mine, near Confidence. The deposit averages 10 ft. in thickness and indications are good. Sinking on the rim has begun with the object of developing the main channel at considerable depth.

Sutter Creek.—The Central Eureka company has completed the construction of its pumping station on the 3900-ft. level. The shaft will be continued for several hundred feet before lateral work is commenced.—The mill at the Argonaut mine is running at capacity on ore being taken from the lower levels. Particularly good ore is exposed on the 4900-ft. level.

COLORADO

Aspen.—The first carload of ore from the Hope tunnel, after deduction of freight and treatment charges, netted the company \$1288. Two other cars of the high-grade ore await shipment. The new boarding-house is completed and additional miners are to be employed. The tunnel is now being extended.

Cripple Creek.—Discoveries are reported from the Gold Hill section, on the Mary McKinney, Rittenhouse, and Lexington properties on the southern slope of the hill. Ore averaging one ounce gold per ton has been opened for 50 to 100 ft. by lessees.—The United Gold Mines Co. has taken over the Hardwood mine of the Damon group and is operating it on company account. The initial shipment has been sent to the Golden Cycle mill.—Diamond-drill prospecting continues at the Cresson and new orebodies are reported. Heavy shipments continue.—The Gold Bond, on the south-western slope of Gold hill, is again shipping. Miss Mollie O'Bryan and associates are in receipt of returns on their first carload shipment. Settlement was made at the rate of \$19.60 per ton.—Sam MacDonald, pioneer mining man and former superintendent of the El Paso Gold King, is extending the Sangre de Cristo tunnel into Tenderfoot hill. He is saving medium-grade ore. The tunnel heading

is in Black Diamond territory, a former producer controlled by the Lennox-Giddings interests.

Georgetown.—Ore sampling 5.2 oz. gold and 4 oz. silver has been opened on the Nancy Smith claim by Dave Kennedy. The property has lain idle for 48 years; it was patented in 1873. The vein is 5 ft. wide with the hanging-wall streak sampling 3.6 oz. gold and 3.4 oz. silver. The vein is pronounced the extension of the Centennial-Capitol veins; the Nancy Smith lies between these two former rich producers.

Idaho Springs.—The Utah Colorado Mining & Milling Co. has commenced development of its Bertha group of 17 claims, situated between the Frontenac and Sun & Moon mines, in Pleasant valley.——The tramway of the Roosevelt company at Alice is nearing completion and the mill will be

silver. It is said to have the appearance of developing into a favorable orebody. The property is $1\frac{1}{2}$ miles north-east of Burke.

The Lookout Mountain property on Pine creek, in the Coeur d'Alene, will have machine-drills in operation soon. Several engineers visited the property and expressed favorable opinions. Assays on sample of the ore show 25 oz. silver, 73% lead, and 12% copper.

In the No. 2 tunnel of the Torina Mining Co.'s property, near Mullan, the vein has been followed 75 ft., showing strong mineralization the entire distance, with occasional showings of a good grade of galena ore.——The Sunshine Mining Co., in the Coeur d'Alene, will start operations at once. The property consists of the Yankee Boy and the Yankee Girl mines, which the company has under lease and

The Men Who Sank a Three-Compartment Shaft 427.5 ft. in 31 Days, for the Walter Fitch Jr. Company

operating on a 24-hour basis by the end of the month. Large reserves of ore have been developed.

Ouray.—The Mountain Top Mining Co. is installing a Hardinge mill and doubling the capacity of its plant. Development of the Agnes vein continues to be favorable.——The Hidden Treasure operating force has been increased to 25 men, the largest number employed to date. Development continues and ore-reserves are being steadily increased.

Silverton.—The Neuville group has been leased to local men who will mine ore from the extension of the rich Yankee Girl vein already exposed and being developed.——Operations have been resumed by the North Star Leasing Co. on the Gladstone. A large tonnage of mill ore is broken.

Telluride.—The Liberty Bell is making its last clean-up preparatory to the final shut-down. It is estimated that the mine and mill have produced in excess of \$10,000,000. The mine and mill machinery it is expected will be sold.

IDAHO

Coeur d'Alene.—At the portal of a new cross-cut tunnel on the property of the Majestic Mining Co., in the Coeur d'Alene, a new vein was discovered. Assays show lead and

bond. They are in the Big Creek district, six miles from the Bunker Hill smelter. E. C. Tousley, of Spokane, is manager. The mill will be of 50-ton daily capacity.

Workmen making the raise from the 400 to the 200-ft. level in the Chicago-Boston mine in the Coeur d'Alene have broken through into the 200-ft. level. When within 25 ft. of the 200-ft. level they cross-cut to the vein and found what they believe is the end of the ore-shoot they have been seeking.

KANSAS

Columbus.—Victor Rakowsky, of Joplin, and O. M. Bilharz, of Baxter Springs, are securing new leases of ore lands in this district and also are purchasing fees of lands. The past few days has seen marked activity in the matter of securing leases on lands east of this city, and a number of other prospectors besides the two mentioned are said to be acquiring additional tracts.

MICHIGAN

Houghton.—The only copper to be shipped out of the Lake district in two weeks was 600,000 lb., by boat on August 5, from the Calumet & Hecla, Copper Range, and Quincy smelters. Half of it was C. & H. metal, made up of

200,000 lb. of small cakes for a Detroit concern and 100,000 lb. of billets for France. Calumet & Hecla has no orders on its books at present, but will continue to keep two furnaces in operation. There are still a considerable number of eupola blocks to smelt, and these will be made up into anodes for the electrolytic plant, being returned as cathodes and held in readiness for smelting into such shapes as may be ordered. C. & H. still has a large amount of mass copper and some mineral at the smelter; this, with the cathodes, will permit filling of orders for special shapes without the necessity of re-casting stock shapes. Recent orders have been comparatively small, and it is believed little difficulty will be experienced in handling all business, under present market conditions, with the two furnaces.

There will be no resumption of mining by Calumet & Hecla and its subsidiaries until there is a marked improvement in the metal market, it is authoritatively stated. There has been some talk of a re-opening of the mines as an emergency or relief measure, but no step of the kind is contemplated.

If the State Board of Equalization adopts the suggestion of the State Tax Commission in fixing the equalized values of the counties of the State, the mining companies will pay considerably less in State taxes this year. The Tax Commission has recommended that about two billion dollars be added to the State's equalized valuation; it has been recommended that Houghton's valuation be reduced from \$99,000,000 to \$90,000,000. If the commission's estimate be adopted, Houghton county's tax rate will be 0.01343 instead of 0.02208 as at present.

MISSOURI

Joplin.—No change was registered in the Tri-State zinc and lead field for the week ending August 6. Zinc ore remained steady at \$21 per ton and lead at \$50. There were rumors that only \$21 was being paid for zinc, and \$51 to \$51.50 for lead, but these could not be confirmed. A week ago one buyer attempted to get ore at \$20, but found it impossible. Demand was not so good, and only 3600 tons was reported purchased. The slab-zinc market continues dull, with no change, national or international, worthy of note. Some slight improvement in galvanizing demand was reported. The sales in the district were reported as follows: Oklahoma: blende 5,561,400 lb., value \$53,380; lead 1,508,920 lb., value \$37,700. Kansas: blende 2,780,350 lb., value \$29,190; lead 227,900 lb., value \$5600. Missouri: blende 1,422,520 lb., value \$14,931. The total sales for the district were: blende 9,764,270 lb., value \$102,521; lead 1,736,820 lb., value \$43,300. Total value for the week, \$140,801.—The Joplin Iron & Metal Co. is making plans for the construction of a \$10,000 store-house. The company suffered a loss of \$25,000 by a fire that recently swept a section of its yards.

MONTANA

Butte.—Butte & Superior is putting its mine in such shape that it can get the most out of the zinc market when quotations again permit mining. It has to date developed ore-reserves amounting to over 462,000 tons, an increase of approximately 40,000 tons over reserves at the close of December 1920. This product will average around 15% zinc and between 5 and 6 oz. of silver per ton. Cross-cutting of the copper vein in the Black Rock mine early this year is now overdue, and the impression in mining circles is that the vein has faulted and possibly in consequence the cross-cut has missed the ore. This will be definitely determined as more work is done. The copper vein was found to be faulted on the 2050-ft. level, where it was originally found, and the possibility is that the vein has flattened. Financially, the company is in good shape to weather a period of illness. It has between \$2,500,000 and \$3,000,000 in quick assets and its expenses have been reduced to a

minimum. Nothing of importance has occurred recently in the litigation with Minerals Separation company. The amount of damages to be paid under Supreme Court decree is being threshed out by accountants under the guidance of Judge Bourquin of the Montana District Court. The mass of figures and details surrounding this accounting confirms the belief of both parties that it will be a long time before the final sum is agreed upon.

NEVADA

Candelaria.—Construction of a 200-ton mill is to be started soon by the Candelaria Silver Mines Co. C. D. Kaeding is managing engineer. His recent report gives an estimate of \$3,546,000 gross above the 200-ft. level, mine ore averaging 14 oz. silver and \$1 gold, with dumps and fills 9.7 oz. silver per ton.

Cortez.—The lower tunnel of the Cortez Silver Mines Co., known as the Arctic tunnel, nearly 2500 ft. long, has penetrated the porphyry dike that cuts nearly vertically through the limestone and quartzite of Tenabo mountain, and a raise has been started to connect with the old Garrison tunnel, 360 ft. above. The upper adit workings produced over \$15,000,000 many years ago, when the mine was owned by George Hearst and Simon Wenban. The bonanza ore-chambers were opened in secondary fractures in the limestone, branching from the main dike. Unexplored blocks of large extent above the upper tunnel level are to be prospected.

Divide.—The Divide Extension has issued a statement saying: "This company has recently developed an orebody on the 100 and 200-ft. levels with five raises about 40 ft. apart. The ore from these raises has been milled by the MacNamara mill at Tonopah and the result was as follows: 495 tons averaging \$83.55 per ton, with a gross value of \$41,373. No stoping has been done in this ore, but we will start on the first of September. The extent in length or depth of this orebody has not yet been determined."—The Brougner has resumed work.

Goldfield.—The shaft of the Deep Mines was 875 ft. deep on August 22. No progress in sinking was made during the first week in this month, because of the necessity for relieving and replacing timbers. The shaft is now being sunk at the normal rate of 5 ft. daily, which should bring it to the 1000-ft. point about September 15. It is expected that the C. O. D. vein will be cut at about 1000 ft. The company is in good financial condition, with enough money in the treasury to sink the shaft to 1000 ft., pay for the timber that will be used from the 1000 to the 1500, and still have surplus funds with which to continue the work while assessment No. 3 is being collected. Sinking to date has cost \$85 per foot, a figure that includes all overhead expense and taxes. A round of holes 6 ft. or slightly deeper is drilled in an average of 1½ to 2½ hours, depending on the kind of ground to be broken. The blower is then started and it removes 3500 cu. ft. of free air per minute from the shaft, which enables the miners to re-enter the shaft in 20 to 30 minutes. The timbers are maintained within one set of the bottom of the shaft, which is made necessary by the condition of the ground. The work is in direct charge of Elmer Burt, superintendent.—The north-east cross-cut on the 800-ft. level of the Red Hill has been driven 155 ft. into the Florence, or 215 ft. from the Red Hill shaft. The strike and dip of the formation is the same as on the upper levels of the Florence and it is expected the vein undoubtedly will be entered within a few feet.

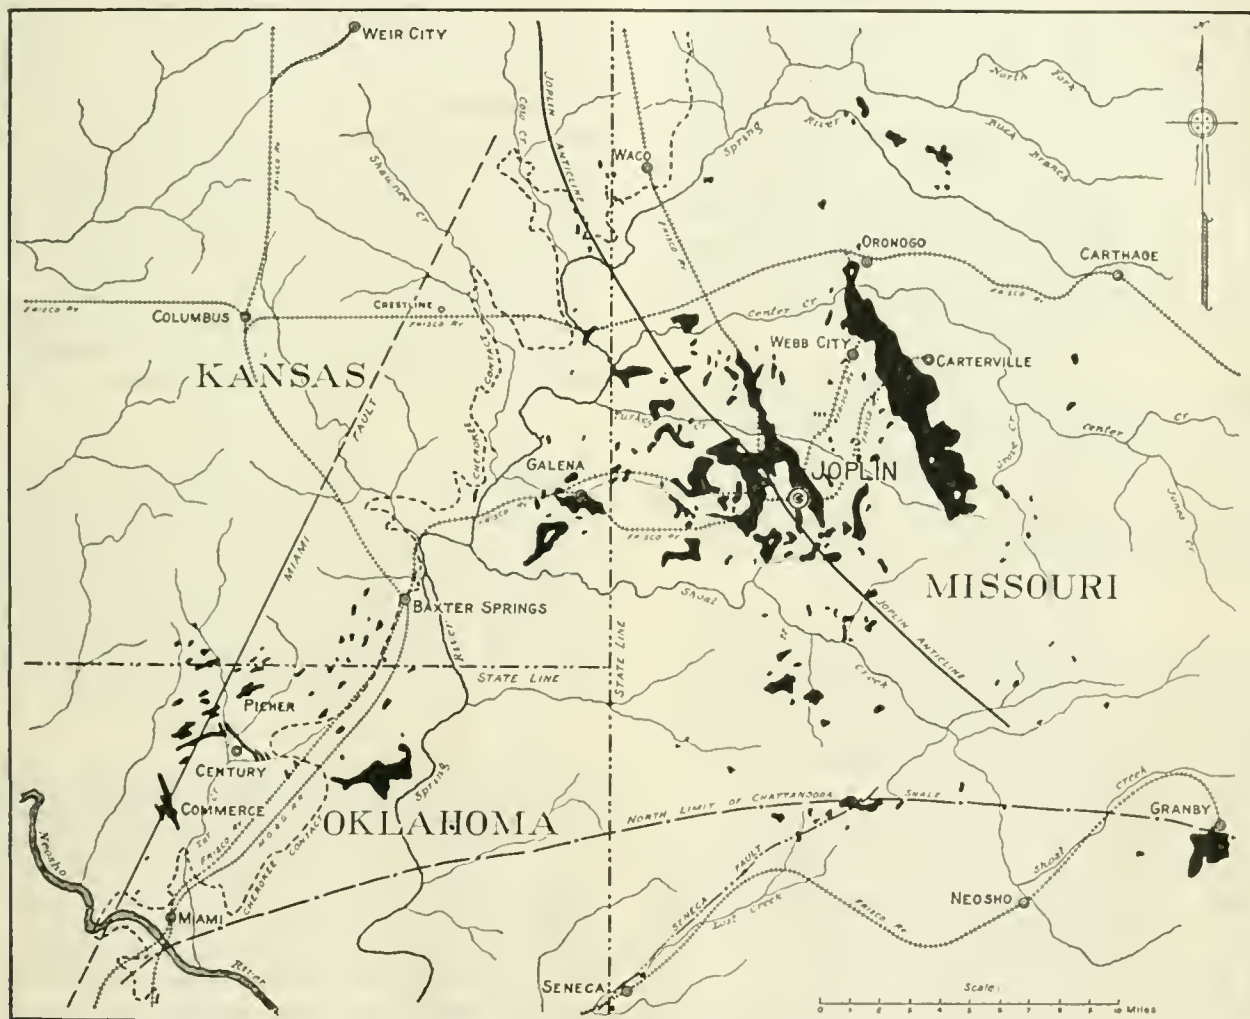

Hornsilver.—The Orleans Hornsilver Mining Co. has taken possession of the Orlean mine from J. W. Dunfee, former holder of the lease and option to purchase from the Champ D'Or. The new company has acquired this lease and the option to purchase. The officers of the Orleans company are: A. I. D'Arcy, of Goldfield, president; R. H. Downer, Gold-

field assayer, vice-president; H. D. King, of the Victory Divide company, secretary-treasurer. The company is incorporated for 1,500,000 shares of stock of a par value of 10c., non-assessable. Dunfee had shipped 11 carloads of \$22 to \$59 ore when the company took possession, the ore of best grade coming from a winze that has been sunk 50 ft. below the 580-ft. level. The shoot has now been opened for a lateral length of more than 100 ft. and a length of 70 ft. on the dip of the vein.

Railroad Springs.—The Allied Mining & Milling Co. has sent letters to stockholders asking them to buy an additional \$20,000 worth of stock to be used in enlarging the concentrator to 100 tons capacity. The company now has a con-

are the Best & Belcher, Gould & Curry, Savage, Hale & Norcross, Chollar-Potosi, Bullion, and Exchequer, extending from the Con. Virginia south to the boundary of the United Comstock group. The sampling of the old workings and dumps was started August 20, under the direction of Albert Burch. R. B. McGinnis is superintendent. The first work was in the Hale & Norcross tunnel and on the surface of the Chollar. The sampling will take from two to three months.

The Comstock Silver Mining Co. has developed mill-ore in its Scheels group, working through the old Umatilla tunnel. Two winzes from this tunnel show pay-ore, the second, 400 ft. from the portal, showing ore uniformly 5 ft. wide. A cross-cut from this winze has broken into an old drift, ap-

The Tri-State Zinc-Lead District

centrator of 50-ton capacity, but during the last year work has been confined almost entirely to mine development because of the low price of lead. The statement issued by the company says: "It is estimated that close to \$1,000,000 worth of ore is in the mine and dumps."

Round Mountain.—A report of the Round Mountain Mining Co. covering the period from January 1 to July 22 of this year says "the costs this year should be less than for 1920, but taking the 1920 costs as a basis, we have an indicated profit from placer operations of \$58,750 for the year 1921". During this period the company received \$11,405 as royalty from lode lessees.

Virginia City.—Options of purchase, involving the so-called middle mines group of properties on the Comstock lode, have been executed to Alex Wise, acting for Philadelphia investors. The properties included in the transaction

parently from the Overland shaft, and this drift is in ore. The property now embraces the old Overland mine, the Scheels group, the Jumper group, together with the Underground and Cosmopolitan claims. The Overland is equipped with well-constructed camp buildings, hoisting machinery, and a 10-stamp amalgamating mill, which is to be enlarged and provided with cyaniding equipment. The various properties in this group have produced about \$2,000,000 from shallow workings in the three main north-trending lodes and four or five cross fissures.

Weepah.—The Electric Gold Mines Co. is cross-cutting west on the 100-ft. level of the main shaft, which has been sunk to 170 ft. This cross-cut is being driven toward the extension of a shoot of \$50 ore that was found in the shaft at 80 ft. This shoot, which has only a slight pitch, is thought to be exposed in another shaft where there is a

6-ft. width of \$40 ore. The shaft is being sunk on the foot-wall of a vein that has been opened for a width of 70 ft. On the surface of this vein, on the hanging-wall side, there has been opened an 18-in. width of ore from which assays of as high as \$600 have been obtained. This ore is quartz containing coarse gold.

NEW MEXICO

Las Cruces.—Official announcement is made that C. A. Peterson and associates of Chicago, who have just bought of C. P. Cramer 32 claims covering practically the entire mineral belt of Georgetown, in Grant county, New Mexico, west of Las Cruces, will soon begin operations on a large scale. The old dumps show more than 200,000 tons of ore averaging \$11 per ton. The cost of mining, milling, and treating by the cyanide process should not exceed \$6 per ton, so the dumps alone should yield a profit. Estimates place the value of the ore in sight at \$150,000. The extensive workings of the old mines make these calculations easy. The property is east of Hanover and five miles northeast of Santa Rita, where the copper mines of the Chino Copper Co. are. The buildings on the property are to be repaired at once. The Georgetown mines are the oldest in Grant county. Silver was discovered there in 1866. The principal producing mines were the Naiad Queen, Commercial McGregor, McNulty, and Satisfaction.

OKLAHOMA

Miami.—W. O. Cralle, president of the Miami School of Mines, announces that the institution will open on September 12, although entrance examinations will be held on September 7. The school has been made a part of the University of Oklahoma and students can now get the first two years of university work at Miami. This will result in a much larger enrollment this year, it is believed.

UTAH

Eureka.—The Eureka Bullion Mining Co. has resumed operations at its property in the East Tintic district, following a shut-down of several weeks. The company is seeking to open on the 1050-ft. level an ore-deposit discovered on the 800-ft. level. This deposit was found on the 925-ft. level, and a drift on the 1050-ft. level gives samples assaying 9 oz. silver and 2.5% lead.

Ore shipment for the week ending August 13 totaled 178 cars, as compared with 152 cars for the preceding period. The Tintic Standard shipped 63; Chief Consolidated, 38; Iron King, 15; Iron Blossom, 14; Eagle & Blue Bell, 13; Victoria, 12; Centennial Eureka, 5; Colorado, 3; Mammoth, 3; Gemini, 3; Dragon, 2; Sunbeam, 2; Swansea, 2; Tintic Drain Tunnel, 2; and Eureka Mines, 1.

During the second quarter of the current year, the Chief Consolidated Mining Company shipped 22,560 dry tons of ore, averaging 0.06 oz. gold, 33.92 oz. silver, 21.28% lead, and 1.52% copper. The average gross value per ton was \$40.02; smelting, freight, and sampling amounted to \$18.46, leaving a net value of \$21.56 per ton, or a total of \$486,352. The net profit for the period was \$45,239, as compared with \$43,012 for the first quarter of 1921. The total amount of development work done during the quarter was 10,452 ft., of which 8145 ft. was drifting, 2208 ft. raising, and the remaining 99 ft. winzes.

Milford.—Work has been resumed at the Independence Silver Mining Co.'s property, following a visit from O. Holm, of St. Paul, president of the company. From prospecting work alone, the company has shipped 27 cars of ore, averaging \$2 in gold, 27 oz. in silver, and 47% lead. The first work will be the sinking of the shaft to the 500-ft. level, according to Edward Bardsley, manager.

Moab.—Andrew Nylund and associates, who have been operating uranium claims in the Gateway, Colorado, dis-

trict, have moved their equipment to a uranium deposit near Thompsons and will begin active mining operations. During the past three weeks 1000 sacks of uranium ore has been shipped from this district.

Modena.—A special meeting of the stockholders of the Bull Valley Gold Mines Co. has been called by M. R. Evans, president, for the purpose of ratifying the action of the Board of Directors in issuing an option and lease to J. M. Worton and Burton S. Rupp, whereby they are granted the privilege of purchasing the property of the company for the sum of \$105,501; \$14,066.80 to be paid within 60 days after ratification, and the balance, \$91,434.20 to be paid within two years. A royalty of 10% on all ores extracted will be paid to the company during the two-year period, such royalties to apply on the purchase price. The holdings of the company consist of 16 patented lode claims in the Goldstrike district, about 40 miles from here. It is stated that free-milling gold quartz is found in a 3-ft. vein that assays as high as \$50 per ton. The milling-ore in sight is estimated at 10,000 tons, averaging \$20 per ton.

Park City.—Shipments of ore for the week ending August 13 amounted to 1485 tons, as against 1562 tons the preceding week. The Judge allied companies shipped 557 tons; Silver King Coalition, 493; and the Ontario, 435.

Salt Lake City.—The United States Smelting Co. has announced a reduction in smelting-rates of 1c. per ounce on silver and 1c. per pound on lead, owing to a reduction in the freight-rate on bullion. The reduction became effective on August 11.

WASHINGTON

Springdale.—At the Queen mine, near Deer Trail in Stevens county, workmen recently broke into 10 in. of ore that carried an average of 1080 oz. of silver per ton. This property is now owned by the Silver Basin Mining Co., in which Charles Turner, of Davenport, and associates are the stockholders.—The Aichan Bee Silver-Lead Mining Co., of Spokane, which owns property adjoining the Queen, intends to install compressor machinery and push the extension of the tunnel, which is now in 477 ft., and continue other development.

BRITISH COLUMBIA

Anyox.—The Granby Consolidated M. S. & P. Co.'s engineers have examined a number of properties recently, among them being the Silver-Standard mine, near Hazelton, the Carmichael property, on Copper river, the Kleanza Copper Co. property, at Kleanza creek, and properties in the neighborhood of Whitehorse, Yukon. The examination of the Silver Standard, which is a silver-lead-zinc property, suggests that the company contemplates the addition of lead and zinc smelting plants to the smelter. With the opening up of the Keno Hill silver-lead deposits, in the Yukon, there should be ample lead ore for a smelter on the northern part of the British Columbia coast, and independent mine-owners in the northern part of the Province would welcome such an addition to the Granby company's plant.

Nelson.—The California Mining Co., owner of gold properties in British Columbia, will resume operations as soon as alterations in the mill are completed. The property is three miles south of Nelson and is composed of the California, Exchequer, and Athabasca groups of 13 claims. The development of the California has been proceeding for several years by the company, which is controlled by Washington and British Columbia interests. The properties adjoin. The Exchequer carries an extension of the California vein, and the Athabasca is in line to carry the vein, but the development necessary to the establishment of proof of continuity has not been performed. All levels of the California have been run to the end-line of the Exchequer. The mine is equipped with a modern mill, a cyanide plant, and an air-compressor, and the machinery is operated by water-power.

Ore is available for immediate milling, but additional development work will be necessary to assure a continuous operation of the mill. J. H. Turner, of Spokane, is superintending operations.

Telegraph Creek.—A. St. Clair Brindley, of Victoria, reports the finding of two important deposits of pyrrhotite, which are said to contain arsenides of nickel and cobalt, in the Ward mining district.

Trall.—Ore receipts at the Trall smelter for the first week in August, which amounted to 8263 tons, contained contributions from ten mines. The following were the shippers: Freddy Lee, Sandon, 24 tons; Knob Hill, Republic, 85; Kokoma, Beaverdell, 8; North Star, Kimberley, 46; Majestic, Sandon, 5; No. 1, Alnsworth, 33; Surprise, Republic, 322; Skyllne, Alnsworth, 20; Whitedater, Retallic, 39 tons; and Bingo, 826 lb. The company's mines shipped 7255 tons.

Vancouver.—George Wingfield, of Reno, Nevada, has filed suit against the Taylor Mining Co., the Taylor Engineering Co., and Charles M. Rolston, of Vancouver, for \$182,322, being the amount of a mortgage and accrued interest on the Dolly Varden mine. When, in the closing hours of the 1920 session, the Provincial Legislature by a special act took the case out of the courts and vested the title to the mine in the Taylor Mining Co., one of the liabilities assumed by the Taylor company was a mortgage in favor of Wingfield for \$150,000, which from non-payment of interest has grown to the above amount. Within the last few weeks the Taylor company has re-opened the Alice Arm-Dolly Varden railway, and has shipped 500 tons of ore that was lying on the dumps.—W. H. Collins, director of the Canadian Geological Survey, has been making a tour of the more important mines of the Province, accompanied by W. Fleet Robertson, Provincial Mineralogist. The director stated that British Columbia was receiving one-third of the total Dominion grant of \$170,000 for research and field work.—H. A. Guess, president of the Premier Gold Mining Co., passed through here recently on his way to the mine. The company is erecting ore-bunkers at Stewart.—J. J. Warren, president of the Consolidated M. & S. Co., returned recently from a trip to the Orient, where he has been in the interest of his company, which has made several shipments of copper to Japan.—Heywood & Co., Ltd., of this city and Calgary, have underwritten \$350,000 worth of shares in the Mount Stewart Oil Co., which has been formed to develop petroleum and natural-gas rights at Fort Norman and at Great Slave Lake.

MEXICO

Casas Grandes, Chihuahua.—Francisco Zorrilla, of Ciudad Juarez, has located El Progreso, a new group of prospects in the Capulin mountains near Casas Grandes.

Chihuahua.—Federico Ramos, of Chihuahua City, has filed on a group consisting of 20 pertenencias, situated in the Santa Eulalia silver district. The group is to be known as the Carmen. It lies adjacent to the Susana, Las Plomosas, and La Union. The Chihuahua smelter is still operating in full blast with eight lead-furnaces. The company has recently acquired a large number of valuable mining properties throughout the States of Chihuahua, Durango, and Coahuila.—About fifty tons of ore is being received at the Chihuahua plant from the San Mateo mines in the Velardena district. Carter Barker, of the Hileta Gold & Silver Mining Co., is arranging to make shipments of ore from Velardena to Chihuahua.—The Ahumada group of ten claims has been filed on and is being opened up by Antonia Zacatecas, of Juarez. The property is situated in Los Lamentos mountains and near the village of Gonzales. The ores carry lead, zinc, and silver.—A strong vein carrying gold, silver, lead, and copper has been discovered and located by Jesus Trevino and associates near Carmen camp. The filing of eight claims has been made at the Parral

mining agency under the name of La Tenoxtitlan.—Leopoldo Felix has made application for title to La Gloria mines, which compose eight claims situated in the Guadalupe y Calvo district.—Marcos C. Jay, of Guadalupe y Calvo, has made a new filing on the Cuatro de Julio group, situated in the Flores arroyo.

Chilipas, Chihuahua.—Lorenzo Diaz has filed on a group of gold and silver mines to be known as Esperanza, situated in the municipality of Guazapares within the jurisdiction of the Chilipas mining agency. La Fabulosa, a group of two promising claims, has also been taken up by Sr. Diaz in the same vicinity. Jacob W. Breach has been appointed to make the official survey and plans for both locations.

Guaymas, Sonora.—Reparation for the murder of Edgar Bristol Davis, an American mining engineer, on March 21, 1921, has been promised. On March 28, Consular Agent J. N. Gibbs, of Cananea, reported the discovery of the body, stripped and robbed, near Mazocahui, Sonora. Guilt for the crime became fastened on a Mexican found to be wearing articles of clothing taken from the dead man. The body of Davis had been robbed of a sum of money which he had been known lately to possess, and his horse, saddle, and camping equipment were also stolen. In addition to the circumstantial evidence, the Mexican had boasted, while under the influence of liquor, of the killing. Although Consul Yost, in whose district the murder occurred, the brother of the slain man, John Davis, manager of the Bunker Hill mine, Tombstone, Arizona, and others have been tireless in their efforts to have the suspected slayer apprehended, no action had been taken by the Mexican authorities; over four months has elapsed in which the party suspected of the murder has been at large.

Hermosillo, Sonora.—It is understood that the Governor of the State is planning to operate some of the principal gold mines of the Ortiz district for the benefit of the State. Employment will thus be given to a large number of idle miners and relieve considerable suffering.

Conferences are being held between State officials and owners of the copper mines. The low price of copper and the lack of fuel and railroad facilities make it difficult for the mines to work profitably.—The Arizpe silver mines have been acquired by Americans, who are making preparations to operate them on a large scale.—A deposit of silver ore is said to have been discovered in the Soyopa mines of this State.

Monterrey.—The Cia. Negociacion Minera Jesus Maria of Saltillo, in which Ernesto Madero is largely interested, is considering plans for the development of its mines in the State of Coahuila.—Albert Genty has just finished the construction of an eight-mile spur-track railroad to his mines at Sierra Ramirez, State of Durango. He has started the development of his Calaverita group of mines in the San Juan Guadalupe district, and will make shipments of ore soon to the A. S. & R. smelter at Aguas Calientes.—An American company is being organized to take over the Salida mines in the Velardena district, State of Durango, which was forfeited for non-payment of taxes.—Juan A. Gallard, of Durango, has obtained title to a group of gold and silver claims in the Huizar mountains, near the capital of the State, and is preparing to start development work.

At the present rate at which forfeited mines are being re-located it will not be long before all of them have been taken up. One of these properties is the Descubridora group, situated in western Durango, which has just been taken up by M. Chavez.—In the Concepcion del Oro district, State of Zacatecas, several groups of claims have been filed on recently. In the Mazapil camp Jose R. Zamora has applied for title to two claims that give promise of becoming copper producers.—William Friedrich, of San Antonio, Texas, and associates are arranging to start

development work upon a group of mines in the Chalcuinites district, State of Zacatecas.—Re-location of the old Anexas de Zaragoza mines, situated in Los Muertos mountains, State of Zacatecas, by J. R. Dyer and associates is announced. The mines will hereafter be known by the name of Tenochitlan. Improvements are to be made.—In the San Juan de Guadalupe camp, State of Durango, Eugene Leroy has acquired title to the Gardenia and Chabasco mines.—Several old mines in the Topia district, State of Durango, have been filed upon by W. Dartling.—The San Francisco Mines of Mexico are having plans made for a 275-ton ore flotation plant which it will build at its San Francisco del Oro mine, in the Parral district. H. G. Hunter is engineer in charge of the property.—The American Smelting & Refining Co. will resume operation of its Tecolote mine in the Santa Barbara district, State of Chihuahua, the latter part of this month, it is stated.

ONTARIO

Cobalt.—Operations have been resumed on the Violet property of the La Rose Consolidated. This has been made possible by reason of the improved economic situation, both in respect to the lower cost of supplies and in the higher efficiency of miners.—The mill on the Hudson Bay mine will be re-opened and about 6000 tons of broken ore will be treated. No development work will be undertaken at present.—During July the Bailey custom mill treated 4043 tons of ore and realized gross earnings of \$12,129.51. The Bailey mine itself shipped 1262 tons of ore during the month.—A number of properties will be re-opened this fall in the Elk Lake district, including the Cane Silver Mines, Triangle Silver Mines, and Ontario Solid Silver Mines.—Road work on the highway from the centre of activity in the Gowganda field to the railhead at Elk Lake is progressing rapidly and, after this year, it will be possible to operate motor-trucks during the summer months. This will greatly reduce transportation charges.—Sinking on the Waldman property of the Oxford-Cobalt Co. has reached a depth of 45 ft. Good assays in silver have been obtained all the way from the surface.

A meeting of the stockholders of the Bailey Cobalt Mines will be held on September 23 for the purpose of concluding an arrangement whereby the company will be in a position to take possession of 425,000 shares of stock in the more recently incorporated Bailey Silver Mines Co., which controls the Bailey Cobalt, together with what was formerly the Northern customs concentrator.—During July the Nipissing mine produced \$166,363, of which \$140,983 was in silver and the balance of \$25,380 in cobalt. The low-grade mill treated 7258 tons; the high-grade plant treated 185 tons. The refinery shipped 370,117 oz. of silver.—Total silver production from the mines in the Cobalt field during July reached a little over 700,000 oz. In the order of their importance, the producers were: Nipissing, Mining Corporation, Conlagas, O'Brien, La Rose Consolidated, Bailey, and Chambers-Ferland.—An interview with officials of such mines as have not yet resumed operations reveals a general opinion that a movement toward general resumption of work cannot be expected until such time as further reductions take place in the cost of material as well as wages to the employees.—The completion of a well-graded road from Elk Lake to Gowganda assures the Gowganda silver-mining field greatly improved transportation facilities for the summer of 1922. The use of motor-trucks is expected to replace the horses and wagons now in general use. The projected light, narrow-gauge railway through the Gowganda district, running from Swastika to West Shining Tree, by way of Fort Matchewan and Gowganda, is still in a state of uncertainty; the promoters have made the announcement that arrangements are being concluded in Toronto and Montreal to sell the bond issue of \$1,500,000.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Charles H. White is at Wallace, in the Coeur d'Alene.

E. R. Richards has left Pioche and is now at Berkeley.

J. K. Turner has returned to Goldfield from New York.

Robert R. Hedley is at the Arlington mine, Slocan, B. C.

W. Earl Greenough, of Spokane, is at Lander, Wyoming.

John P. Gray, of Coeur d'Alene, Idaho, was at Salt Lake City recently.

H. V. Winchell is examining the Dundee-Arizona mine at Jerome, Arizona.

Frank W. Royer has returned to Los Angeles from Virginia City, Nevada.

Harry Sordy, superintendent for the Alameda Mines Co., of Alameda, Oregon, is in Alaska.

Louis J. Joubert, who has been at Medellin, Colombia, is at Camptonville, California.

Earl H. Young has been appointed Professor of Geology in the Montana School of Mines.

C. N. Schuette is manager for the Silver Gulch Mining & Milling Co. at Dunton, Colorado.

E. P. Mathewson has been appointed consulting engineer to the Burma Mines, Ltd., of London.

Scott Turner has returned to Toronto from a visit to the Granby company's plant at Anyox, B. C.

John Dern, of Salt Lake City, sailed from New York on August 16 for an extended tour of Europe.

R. B. Lamb, of New York, is inspecting mining property in the Clifford district, Nye county, Nevada.

George S. Rice, of the U. S. Bureau of Mines, was in San Francisco this week on his return from south-eastern Alaska.

Albert Burch has been at Virginia City in connection with negotiations involving a group of mines on the Comstock lode.

A. E. Radner, of Bessemer, Michigan, who is in charge of iron-mining operations on the Gogebic range, is at Virginia City.

Clyde E. Williams has succeeded O. C. Ralston as superintendent of the Northwest Experiment Station of the U. S. Bureau of Mines.

P. H. Reagan, of Big Springs, Texas, has become engineer for the Gulf Mining & Reduction Co., at San Antonio, Baja California, Mexico.

Charles Bocking, manager, and E. V. Daveler, mill superintendent for the Butte & Superior Mining Co., were at Salt Lake City last week.

J. F. Callbreath, Secretary of the American Mining Congress, on August 24 delivered an address at the Engineers Club, San Francisco, on 'The Mining and Oil Industry'.

Edward H. Wisser has left the engineering department of the Shasta Zinc & Copper Co. to become mining engineer to the Silver Gulch Mining & Milling Co. at Dunton, Colorado.

F. G. Janney, who resigned recently as general superintendent for mills for the Utah Copper Co. at Garfield, is in New York, where he will be Eastern representative for the Stimpson Equipment Co., of Salt Lake City.

J. F. Sleeper, chemist and author, lately manager for Ricketts & Co., Inc., and research analyst for the testing laboratories of New York, Inc., recently resigned from the latter position and will be open for engagement in September.

R. A. Hardy, superintendent of mines for the United Comstock Mines Co. at Gold Hill, Nevada, is on his way to Alaska to inspect the Alaska Gold mill. Some of the equipment is to be moved to the site of the United Comstock's 2000-ton mill, now in course of construction.

THE METAL MARKET

EASTERN METAL MARKET

(By wire from New York)

August 22.—Copper is inactive but steady. Lead is quiet but firm. Zinc is dull and unchanged.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

ZINC DURING FIRST HALF OF 1921

Figures compiled by C. E. Siebenthal and A. Stoll, of the U. S. Geological Survey, from reports submitted by all zinc smelters which operated during the first six months of 1921, show that the production of zinc from domestic ore in that period was 100,781 short tons, and from foreign ore 1744 tons, a total of 102,525 tons, as compared with 205,269 tons in the last half of 1920 and 258,108 tons in the first half. The stock of zinc held at smelters and in warehouse June 30 was 94,747 tons, having increased from 71,037 tons at the end of 1920 and 29,892 tons at the middle of that year.

From the foregoing figures and from the statistics of imports and exports as recorded by the Bureau of Foreign and Domestic Commerce, it is calculated that the apparent consumption for the period was 83,965 tons, as compared with 147,783 tons in the last half of 1920 and 175,268 tons in the first half. In addition to the zinc produced from ore, 11,950 tons was re-distilled from zinc ashes, skimmings, and drosses. Much of this zinc was of grades above prime Western, and the total, added to the primary output, gives 114,475 tons, consisting of 13,358 tons of 'high' grade, 1100 tons of 'intermediate' grade, 17,466 tons of 'select and brass special' grade, and 82,545 tons of 'prime Western'. Electrolytic zinc amounted to 4617 tons, as compared with 27,591 tons in the last half of 1920 and with 24,035 tons in the first half.

The total number of retorts at plants at which there were some operations during the first half of 1921 is 123,528, as compared with 158,545 at the end of 1920. The number of retorts in operation on June 30, 1921, was 36,000, as compared with 50,000 at the end of 1920 and 95,000 on June 30, 1920. The average quoted price for prime Western zinc at St. Louis for the first six months of 1921 was 4.85c per pound, as compared with 7.8c for the year 1920. The price at the beginning of 1921 was 5.6c, but a steady decline brought it to 4.63c at the middle of April. After rising to 5c by the end of the month, it again fell by degrees and closed the half-year at 4.25 cents.

The demoralization of the zinc industry during the half-year with imports of 7405 tons, exports of 2255 tons, and apparent consumption of 83,965 tons, is strikingly shown by comparison with the two periods of 1919 and for the first half of 1920, when imports were nothing, exports from 70,000 to 90,000 tons, and consumption from 160,000 to 175,000 tons. The output of zinc by Belgian smelters in the first half of 1921 was 35,858 short tons, as compared to a total of 91,542 tons in 1920. The output in June was 4817 tons. It is understood that the monthly output has been limited by the Federation of Belgian Zinc Smelters to 5000 tons. World zinc stocks have been recently stated as about 160,000 short tons, exclusive of the stocks of sheet zinc, of which Belgium is reported to hold 45,000 tons.

MONEY AND EXCHANGE

Foreign quotations on August 23 are as follows:

Sterling, dollars:	Cable	3.67%
	Dem-and	3.68%
Franc, cents:	Cable	7.80
	Demand	7.82
Lira, cents:	Demand	4.51
Mark, cents		1.21

Eastern Metal Market

New York, August 17.

Buying of most of the metals is of moderate proportions, but the undertone of all the markets is fairly strong.

Demand for copper is light but prices are firm at recent low levels.

Buying of tin has been fairly good on a declining market.

The lead market is firmer and buying has been moderate.

There is no improvement in zinc, which remains steady at recent low levels.

IRON AND STEEL

The recent low dip in pig-iron prices led to buying on a scale probably not equaled in a year, and producers of foundry iron in all districts shared in the business. A good many consumers whose stocks had run down sensed the possibilities of the low rate to which output had fallen and decided to buy. In the past week furnaces at Chicago, St. Louis, Buffalo, and in Ohio and Pennsylvania districts have advanced their prices by 50c. to \$2 per ton in an effort to limit the losses they have been making on raw material bought last year. While the extent of the actual rebound in the market is uncertain, the firmer stand of producers is marked and its effect will be closely watched.

The situation in finished steel differs from that of pig-iron. Steel works are being run and none are dropping out of the race. Buyers do not believe that the low point has been touched and are working close on stocks. The past week has shown continued irregularities in prices—on some products rather more resistance to declines—but generally a willingness to meet competition.

COPPER

There is no improvement in demand, which continues of moderate proportions. Reports from consuming centres to some sellers are that business is better and on the whole the future seems brighter. There seems to be no sellers of electrolytic copper below 11.75c., New York, or 12c. delivered, and some reports are to the effect that this price is disappearing. Current demand is being largely satisfied, however, at 12c., delivered. Some producers continue to remain out of the market. For future delivery 12.12½c. is quoted for September, with 12.25c. asked for October. Buying for foreign consumption has been fairly good recently.

TIN

The market, both at London and New York, has declined in the last week and the lower prices have attracted some interest. On two days last week a fair amount of business was done in future Straits tin. On the 11th about 150 tons was sold to dealers at around 26.62½c. and on the 12th about 600 tons was bought largely by consumers as low as 26 to 26.37½c. Since then the market has been stagnant. Straits tin, spot delivery, yesterday was quoted at 26.12½c., New York, as compared with 27.75c. a week ago and there has been a decline of about £8 per ton in London, where yesterday spot standard was quoted at £154 15s., future standard at £156, and spot Straits at £155 10s. Tin has appeared cheap to some buyers and a fair business has resulted. Arrivals thus far this month have been 2710 tons with 2810 tons reported afloat.

LEAD

A much better tone to the market is reported from most sources. Buying continues moderately good; prices are becoming firm and it is acknowledged that the lead market is the strongest of all. The leading interest continues to quote 4.40c., New York and St. Louis, but independents are asking 4.45c., New York, and 4.25c., St. Louis, and getting some

business. Some reports are that the leading producer has stopped taking business.

ZINC

The market has turned exceedingly quiet again and sales are confined to small lots. There is a report that 4.15c., St. Louis, has been done, but this is doubted and cannot be confirmed. Current demand is being satisfied at prevailing quotations, which are 4.20c., New York, for prime Western for early delivery. For future delivery there is not much inclination to quote, but when bids are met, about five points higher are asked for September and October, respectively.

ANTIMONY

There is very little interest reported and prices have dropped to 4.50c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is obtainable from importers as low as 19c., New York, duty paid, but the leading interest continues to quote 24.50c. f.o.b. plant, for wholesale lots for early delivery.

ORES

Tungsten: There is practically no business and no change in quotations which remain nominal at \$3 upward per unit, depending on the grade of ore.

Ferro-tungsten is inactive with prices nominal at 50 to 55c. per pound of contained tungsten.

Molybdenum: There are no developments with quotations unchanged at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: High-grade ore for blast-furnace use could probably be bought as low as 20c. per unit, seaboard, but there has been no test of the market.

Ferro-manganese: There are inquiries for about 500 tons but thus far sales this week have been confined to carload lots at prevailing quotations. The domestic alloy is held at \$70 per ton, delivered, while the British is obtainable at \$65, seaboard.

Spiegeleisen: Demand is confined to small and carload lots for which \$26 to \$27, furnace, is easily the ruling price.

Ferro-silicon, 50%, is in only moderate demand at around \$60 per ton, delivered.

MEXICAN OIL INDUSTRY

If a balance were to be struck today, and the foreign investment in Mexico's oil closed out, it would be found that few companies, if any, have received enough income to repay them, says the latest issue of 'The Lamp', published by the Standard Oil Co. of New Jersey. They are dependent upon the future for the amortization of their capital advances.

Since July 1, when the new taxes went into effect, the situation as regards the most valuable oil, Southern light crude, has been as follows:

Average value of a barrel of this oil in the United States.....	\$1.30
Actual operating costs of a typical large company for four months in 1921, excluding depreciation and depletion, per barrel.....	0.31
Royalty	0.05
Average cost of transportation to various points in the United States	0.43
Taxes under decrees of May 24 and June 7.....	0.34
Total	\$1.15

The margin remaining, out of which the producer must recover cost of wells, leases, pipe-lines, terminals, etc., is 15 cents.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

EFFICIENT MINE VENTILLATION

Mining engineers agree that the efficient ventilation of mines consist in the supplying of such volumes of circulating air at all working places as will enable the miners to work in comfort at maximum physical capacity with unimpaired health. Dau Harrington, mining engineer of the Bureau of Mines, in Technical Paper No. 251, says: "As regards the cost in dollars and cents, adequate and controlled ventilation would be justified by decrease of time lost by underground workers, by saving in compressed air used for blowers, and by better control of mine-fires. * * * With moving air-currents at working faces, workers may save as much as 50 to 70 % of the time which is now lost in seeking relief from hot, humid, or vitiated air".

Charles A. Mitke, efficiency engineer, of Bisbee, Arizona, in his recent book, 'Standardization of Mining Methods', shows by carefully prepared charts covering an experience of 2½ years the following economies obtained where an efficient mechanical ventilating system was installed: The quantity of compressed air used was decreased approximately 50 %. The tonnage per man increased from about 2½ tons to 7 tons, or approximately 180 %. The cost of mining the ore decreased about 45 %.

The ideal ventilation system supplies a sufficient volume of fresh air to dead ends, 'hot-boxes', shafts, stopes, raises, and winzes, and lowers the heat and humidity of these working places, making conditions more comfortable and more similar to those above ground. Without proper ventilation miners are able to work for only short periods until working conditions become difficult and it is necessary for them to go to the nearest air-course for relief. With efficient ventilation they are enabled to work comfortably without interruption and with increased physical ability. This saves a great labor waste with which mining superintendents and bosses are thoroughly familiar. High humidity in the mine-air is a cause of discomfort to workers almost equal to high temperature. When the two are combined a man's efficiency is at its minimum. While the increase of velocity and volume of air blown into a working place does not always reduce its temperature, the working conditions are almost certain to be greatly improved through a reduction in humidity.

In blasting, where a sufficient supply of air is supplied at the face, the miners are able to resume work within a few minutes after the blast, saving on an average at least one-half hour after each shot, and in all cases providing a much healthier working atmosphere.

By adequate mechanical ventilation the mining engineer can not only save time and increase production in blasting, but he can control all the relations existing between heat, humidity, gases, and evaporation in such a way as to avoid the other large losses of efficiency resulting when these important elements are neglected. To accomplish this a direct and dependable simple system for cheaply delivering large volumes of air anywhere in the mine is required.

Because of the conditions existing underground, a system of flexible easily portable tubing of large size is undoubtedly the best means by which to deliver an adequate supply of

moving air to the working places. No objection has ever been offered to this system, excepting the failure of the tubing fabrics previously employed sufficiently to withstand the acid, fungus, and other destructive elements found underground.

The Du Pont company, one of the largest manufacturers of specially-treated impervious fabrics, has, through its intimate knowledge of this type of manufacturing, been able to produce a fabric which not only meets all the mechanical requirements of installation and service, but which has a chemical stability affording maximum resistance to the destructive agents encountered.

This fabric is not only extremely rugged and of great toughness and tensile strength, but its treatment is such as permanently to endow it with the required resistant qualities. It is in the development of this special fabric, called 'Ventube', that the Du Pont company claims a great advancement in mechanical ventilation.

'Ventube' is waterproof and fungus-proof and is highly resistant to the acid and gaseous conditions existing underground. This was thoroughly demonstrated by exhaustive tests extending over a period of 18 months in mines where these conditions are particularly severe.

By the use of 'Ventube', which readily conforms to any angle or curve, any part of the mine, regardless of how irregular its approaches, can be quickly reached. A single workman can put up 2000 ft. of 'Ventube' in one shift, without the use of any special tools, and can take it down as easily. Every part of the equipment used for coupling and suspending 'Ventube' in any position is simple, substantial, and practically fool-proof.

The tubing is supplied in standard lengths of 25, 50, and 100 ft., in standard diameters of 8, 12, and 16 in. One man can easily carry 100 ft. of 16-in. 'Ventube' on his back.

The ends of all 'Ventube' sections are equipped with Braly patent ring-couplings. All that is necessary to fasten two sections together is to squeeze either one of the rings to reduce its diameter and slip it through the other. Then pull back so that the edge of the inside ring rests snugly against the flange of the outer ring. The 'Ventube' fabric acts as a gasket and prevents leakage at the joint.

Fittings such as L's, Y's, T's, angles, reducers, screens for use in raises, fan-nipples, 10-ft. sections for raises, and offsets are all supplied in 'Ventube' material with regular 'Ventube' couplings in all standard sizes.

In all these fittings the use of exposed metal parts has been avoided, thus giving a life equal to that of the tubing itself and affording the same ease of connecting and repairing. As a support for 'Ventube' No. 8 B. & S. gauge galvanized-iron wire hung close to the roof and stretched tightly is recommended. Supports should be about 15 ft. apart but close enough to prevent sagging. The 'Ventube' is hung from the supporting wire by suspension hooks furnished for attachment in grommets provided in the suspension seam of the tubing.

For hanging 'Ventube' in shafts or raises a special suspension-collar is fitted around the regular coupling and supported so as not to pull upon the section of tubing above it.

Where 'Ventube' is run up-grade a suspension-collar is attached to the last coupling and supporting wires are run from it to a clamp on the suspension-wire or to a convenient sprag.

Each line of 'Ventube' should have one special end-piece supplied with snap-hooks to be used as the blasting-piece. In extending the line as the face progresses additional sections should be inserted in the line just behind the blasting-piece, so that the hardest wear will be confined to this piece and practically all the patching will be done on it.

The blasting-piece is usually a 100-ft. section suspended by snap-hooks from a separate parallel supporting-wire running back into the workings about 200 ft. When in its advanced position, the rear of this piece is coupled to the main line, but before blasting the blasting-piece is uncoupled and quickly withdrawn upon its suspending wire. This is quicker and better than rolling or dragging this piece through the mud and water underfoot.

The Du Pont company supplies a special cement for permanent patching. Patches of 'Ventube' cloth are used. The torn section is deflated and the surface around the tear or hole and the surface of the patch are thoroughly washed with gasoline and a coat of cement applied to each. When this has dried, a second coat is applied and left to dry. The cemented portions are then hammered together between flat surfaces to secure perfect adhesion. The repaired section may then be immediately re-connected to the line, the patch becoming virtually a part of the tube. For temporary repair underground, a small patch can be quickly sewed on, if desired, and will usually answer the purpose very well.

WORLD'S BUSIEST BRIDGE DISMANTLED BY OXY-ACETYLENE TORCHES

The Rush Street bridge, at Chicago, the use of which has been discontinued since the opening of the new boulevard link-bridge, has been sold to a wrecking company for junk. The company that purchased the old bridge for \$500 is using 'Torchweld' cutting-torches for all metal-work on the structure. Dismembered steel beams are dropped upon barges anchored beside the bridge and floated away. It is estimated that approximately 250 tons of metal will be salvaged for junk. The first bridge across the Chicago river at this point was erected in 1854, a wooden structure which was destroyed by the Chicago fire in 1871. In 1874, the bridge now being wrecked was built at a cost of \$50,000. It was 240 ft. long and 60 ft. wide, and until 1900 was operated by steam. The Boulevard connecting-link bridge, which replaces the Rush Street structure, was completed recently at a cost of \$16,000,000.

SYNCHRONOUS MOTOR CONTROL-APPARATUS AND EXCITERS

Supplementing the thorough description of synchronous motors given in its Bulletin No. 41,309, the General Electric Co. has issued Bulletin No. 48,032. In this bulletin the description of synchronous motor control-apparatus is divided into four sections: exciters, compensators, panels, and rheostats. There are four general types of exciters. These are direct-connected exciters, DD-0; direct-connected exciters, DS-2; belted exciters; and exciter motor-generators. In general, the bulletin says, direct-connected exciters are used with high-speed motors of over 500 or 600 r.p.m. For the slower-speed motors, it is cheaper as a rule to use belted exciters. For very large machines, or where it is desired to excite several machines from one exciter, motor-generators are recommended. The bulletin describes, with illustrations, the five standard types of direct-connected DD-0 exciters and the two types of belted exciters, as well as the other types mentioned. The four general types of compensators for use with synchronous motors are covered in similar de-

tail, as is the case with the switchboard panel equipment and the rheostats. Diagrams of connections, and tables of compensator dimensions and of compensators for use with different motor-types, are included.

COMMERCIAL PARAGRAPHS

The American Manganese Steel Co. has moved its Western sales-office to the site of its plant at Oakland. The company's new post-office address will be Oakland Pier, Oakland, California. J. W. Plant is manager.

The Hercules Powder Co., of Wilmington, Delaware, has announced a reduction of $\frac{1}{4}$ c. per pound on all high explosives manufactured by the company. The new prices are to become effective immediately.

P. R. Hines has resigned as sales manager for the Dings Magnetic Separator Co., and has opened an office at 703 Lewis Bldg., Portland, Oregon, to do consulting work upon crushing plants, and concentrators, as well as to represent the Stephens-Adamson Mfg. Co. in the North-West.

The Leroy A. Kling Advertising Co. announces its incorporation under the name of Kling-Gibson Co. The members of the firm are Leroy A. Kling, Hamilton Gibson, Harry C. Phipps, William R. Durgin, and Charles J. Keller. Their office is in the Consumers Bldg., 220 So. State St., Chicago, Illinois.

The Armstead Mines Co., of Talache, Idaho, announces that the General Engineering Co., of Salt Lake City, has been retained as consulting engineer in connection with the design and construction of a 150-ton mill. Work was started on July 25; it is expected that the mill will be completed and operating by the end of the year.

The Allied Machinery Company of America, 51 Chambers street, New York City, has been appointed representative in all countries except the United States and Canada for the Universal Crane Co. The Allied Machinery Co. has offices in all the large countries of the world. The Universal Crane Co. makes 3- to 4-ton portable gasoline or electric locomotive-crane.

Bulletin No. 63, recently issued by the Wellman-Seaver-Morgan Co., describes the Wellman revolving ear-dumper. This particular machine has been developed to meet the demand for a low-capacity machine, of simple construction, adaptable to plants where the first cost of installation is a governing factor, but where high efficiency, low operating cost, and minimum labor are required. It is a machine that is recommended by its simplicity and its ready adaptability to existing plants as well as to new plants.

The Cleveland office of the Sullivan Machinery Co. was moved, on July 1, from 810 Park Bldg. to room 824 Kirby Bldg. Ralph T. Stone is manager at Cleveland. The company also announces the establishment of a supply-depot and service-station for coal-mining machinery supplies and repair-parts at 7th avenue and 13th street, Terre Haute, Ind., with H. T. Wiley, formerly of the engineering department at the Claremont works, in immediate charge. This service-station will handle orders from the coal-mining customers of the company in Indiana and will be under general charge of M. C. Mitchell, manager for Illinois and Indiana, at the Railway Exchange Bldg., St. Louis, Missouri.

'Grinding Data No. 6', issued by the Hardinge Company, describes the performance of 3-ft. Hardinge ball-mills in metallurgical plants in the United States, Mexico, and Canada. The operation of the mills, both as primary grinders and as re-grinders, is described, the following details being supplied in connection with each installation: name of the company, character of material, size of the mill, size-analysis of the feed and of the product, the capacity, the speed, the power consumed, and the consumption of balls per ton of material ground. The booklet is arranged for loose-leaf binding, and the data are presented in compact form.

T. A. RICKARD. . . . Editor

THE next meeting of the Institute will be at Wilkes-Barré, in Pennsylvania, on September 12 and the three days following. It was at Wilkes-Barré that the Institute was founded fifty years ago, so that the occasion will mark the semi-centennial anniversary. Local arrangements are in the highly competent hands of Mr. R. V. Norris, assisted by Mr. Paul Sterling, as secretary. Anthracite coal and its production will be the chief topic of discussion.

DURING his recent visit here Mr. J. F. Callbreath, of the American Mining Congress, had to acknowledge regretfully that the McFadden bill is most unlikely to pass, by reason of opposition, among others, from the Secretary of the Treasury. Undoubtedly if this legislation had been introduced earlier, during the War, when the mining of gold was so severely handicapped, it would have commanded more support in Congress. Since then the conditions affecting gold mining have improved greatly and at the present time the outlook is brightening to a most encouraging degree. Mining for gold will be a marked feature of the general expansion of industry that will follow the present depression.

IN our 'News' department we quote from a speech delivered recently by Mr. F. H. Hamilton as the chairman at the annual meeting of a mining company in London. He strikes a virile note that rings pleasantly in times like these, particularly to the gold miner, for it is of the future of gold mining that he speaks. His reference is chiefly to the world's premier goldfield, but what he says applies equally well much nearer home. Our readers will note his confident prediction that the discount on the paper pound sterling is no temporary matter, and therefore that the so-called premium on gold in the countries using the British pound and other depreciated currencies will continue for some time, to the encouragement of gold mining outside the United States, where the dollar remains at a parity in terms of gold.

IN a recent issue, referring to mining in Siberia, we connected Mr. J. Power Hutchins with the Russo-Asiatic Consolidated Company. This was an error. He has long been connected professionally with the Russian Mining Corporation. The American engineers identified with the technical work done by the Russo-Asiatic are Messrs. R. Gilman Brown, H. H. Knox, T. J. Jones

D. P. Mitchell, and A. W. Stickney. The blunder was inexcusable, as we happen to know something about the history and technical progress of these companies. Incidentally we note that negotiations between the London board of directors of the Russo-Asiatic Consolidated and the Soviet government of Russia, for a resumption of mining operations in the Altai, are making good progress. In these negotiations the Russian government is represented by Mr. Leonid Krassin, and the company by Mr. Leslie Urquhart, who is chairman, and the founder of the company as well. Indeed to Mr. Urquhart is due much of the British exploitation of Siberian mining districts during the last ten years. In his work he has had the valued assistance of Messrs. H. C. Hoover and R. Gilman Brown, together with other American engineers, but the fact that he was born in Russia and knows the ways of the country intimately has helped greatly in smoothing difficulties. At last accounts he was in Moscow with five technical experts to arrange the last details of an agreement that is to facilitate a resumption of mining operations. Such a resumption is a matter of personal interest to many American mining engineers, to whom Siberia proved attractive in the days before the bolshevist chaos.

EXEMPTION from payment of tolls for American ships passing through the Panama canal is a subject that is being raised repeatedly in the press of this country. It is evident that public opinion, in Congress and outside, is in favor of such a step. Great Britain knows that the United States is considering the question, and wonders whether action is to be taken in defiance of the Hay-Pauncefote treaty, or whether an agreement will be made between both signatories beforehand. Recently it was stated at Washington that the question would be shelved until after the Disarmament Conference. We consider that this would be a grievous mistake. If the impression is given that outstanding matters of international dispute cannot be settled amicably by diplomatic means then it is evident that we should not expect any European nation to enter the Disarmament Conference without a suspicion that something will be 'put over'. Such an attitude would be fatal to the spirit of fair play that should animate the proceedings. So long as there is any sentiment in this country in favor of disregarding an international treaty or of interpreting it in a manner different from that adopted by the other signatory, it is

obvious that it is no time to propose disarmament. The keystone to any plan for disarmament is the assumption that all disputes can and should be arbitrated by negotiation. An amicable settlement of this particular question is inevitable eventually; why not now?

AT the second International Conference of Pure and Applied Chemistry, held recently at Brussels, the following recommendations relating to the unification of abstracting were proposed by the National Council of the Netherlands: That the Bureau of the International Union take the initiative in bringing together representatives of chemical journals that publish abstracts, with a view to discussing the formation of a central publication and its probable cost; and that the possibility of publishing an international chemical card-index be investigated, together with the approximate cost of establishment and maintenance. Unfortunately, mining and metallurgical engineers are more insular than their confreres in such matters; they hold no international meetings for the discussion of matters of general import; world-wide efficiency and economy in their own profession are obscured usually by national aspirations. Perhaps after the Disarmament Conference we may be in a better mood to co-operate. The results of the initiative of the chemical engineers in the matter of co-ordinating the work of abstracting and indexing will be watched with interest.

DISARMAMENT has been recognized by Great Britain as an effective method of preventing the economic waste that results from incessant warfare. For instance, when a large portion of New Guinea became a British Protectorate it was found that practically every tribe was at war with every other tribe. This condition arose because the Papuans were primitive folk: the bestial idea of killing for sport and for food was inherent with them. Moreover, the country was in chaos because almost every tribe had its own language, so that, where argument or conciliation was impossible, fighting was inevitable. The first Governor promulgated laws that ensured the destruction and confiscation of all weapons, and prohibited their manufacture. This was the first step in the right direction. The second edict prohibited the manufacture by, or the sale or gift of alcohol to, the natives; it was realized that alcoholism and belligerency go hand in hand. The history of Papua since that time has been one of unbroken peaceful development. Where the colonist goes, 'pidgin' English is spoken; it is not an ideal means of communication, but it is better than none; as Cecil Rhodes said, a common language is the greatest aid to peace. The principle of disarmament is economically sound; it should be adopted on a larger scale. The moral support of all the civilized peoples of the world is needed at the forthcoming conference at Washington. War may provide an opening for the higher qualities of human nature, but it also encourages the lowest passions; it leads to destruction and chaos. There are plenty of opportunities in

peace time for the exercise of the virtues of courage and loyalty. The world would be a better place if a spirit of tolerance, brotherhood, and understanding were to take the place of the virtues of the battlefield.

SPEAKING of the sovereign balm of humor, a writer in the 'Valve World' soliloquizes thus: "To me one of the most cheering and hopeful assurances of continued cordial relations between the people of the United States and of Great Britain is given by the attitude of the two leading Anglo-Saxon humorous periodicals—'Life', in America, and 'Punch' in England. After a week of reading in the newspapers about all sorts of agitation and loud talking and raucous threatening and wild jabbering and senseless drivel on both sides of the water, how refreshing to open 'Life' and 'Punch' and see there the friendly and understanding smile, hear there the hearty laughter, read there the sentiments of tolerance and friendliness, of cordiality and genuine brotherhood. There Uncle Sam cracks his joke with John Bull, and John Bull sits down to a little friendly game with Uncle Sam, and the joke carries the essence of understanding and sympathy, and the game enlists our interest and invites our hearty co-operation. Humor is the sovereign balm for many of our fancied ills; so long as we can laugh and smile with 'Life' and 'Punch'—and the laugh and the smile will do us a world of good—we can afford to view without alarm the frantic efforts of malcontents to make Uncle Sam and John Bull quit joking and playing, and take to pulling hair." This is good philosophy; let us laugh more with, rather than against, our friends across the water.

UNDER 'Discussion' this week we publish a scholarly contribution from Mr. H. W. Turner on the magmatic origin of the principal copper minerals in the Engels orebodies. He makes a good case for his side of a most interesting argument. Next comes a plea for a protective tariff on magnesite and chrome. It will, undoubtedly, be read sympathetically by the Californian representatives in Congress. Mr. Albert E. Maas testifies concerning the alleged fabulously rich placers in Sinaloa, apropos of our reference to an absurd story published in the 'Examiner'. Undoubtedly the reporter is responsible for most of the exaggeration, but what can one expect if one gives an interview to a paper like Hearst's? Mr. J. H. G. Wolf makes an excellent suggestion for the indexing of current literature. Mr. A. D. Ramel, a prospector, writes in protest against the proposed revision of the mining law, and his letter is endorsed by five of his comrades. Undoubtedly the revision is most unpopular among the prospectors, and our legislators at Washington should take good note of the fact. In regard to the \$50 per acre to be paid on claims that lack a discovery, we have received letters of inquiry as to whether the figure may not be a misprint, in view of the fact that the lump sum payable annually in lieu of assessment work is only \$5 per acre. The text as sent to us says "fifty", not in figures but spelled. Five dollars

per acre in lieu of annual work comes to \$100 on a 20-acre claim. This therefore is an alternative, not an increase. As to the \$50 per acre, that applies to special conditions, namely, to a claim on which no discovery of a vein or lode has been made. Such a claim, as stated in Section 5, Clause B, may be held for five years, after which it becomes subject to re-location; but an opportunity to hold it for a further period, not exceeding five years, is given on the condition that the locator pay \$50 per acre annually, such payment to include the requirement for assessment work. To pay \$1000 per annum on a 20-acre claim is a heavy tax, but, it must be noted, it is due only on a claim upon which no discovery has been made after five years, and which therefore presumably has become potentially valuable only on account of the successful development upon adjacent ground. The regulation is meant, we suppose, to check the indefinite holding of claims by those unable or unwilling to explore and exploit them. It is hard on the prospector who holds the location in the expectation of selling it, without himself having done any successful development, and to that extent it plays into the hands of moneyed persons. Mr. William Crocker sends a thoughtful and most acceptable letter on the subject of allowing non-American issues to create dissension among our people. Incidentally he describes the compromise system of voting, which is ingenious and in accord with democratic principles.

Amalgamation and Cyanidation

A definition of an 'expert' may well include the qualification that he appreciates the limitations of his own specialty. The experienced cyanide engineer should be the first to realize the fact that only in exceptional cases could cyanidation entirely displace amalgamation without incurring avoidable losses. In the 'South African Mining & Engineering Journal' we note some interesting reminiscences from the pen of Mr. Andrew F. Crosse, to whom the profession is indebted for the results of much scholarly research and scientific interpretation. We learn of the first use of compressed air in the cyanide treatment of a gold ore on the Rand, and of the inventor's indifference to financial gain, for he never patented the idea and so saved the industry the economic waste of litigation. Speaking of the importance of amalgamation, Mr. Crosse compares the neglect to utilize this process, wherever practicable, to the attitude of a shopkeeper who would refuse to deal with any but credit customers. Gold obtained by amalgamation, as Mr. Crosse remarks, is ready cash.

In reviewing the recent history of the metallurgy of gold it is interesting to note how the industry has been swayed locally by fashion; and fashion insists, first of all, on the discarding of what is not strictly up-to-date. All-sliming was and is necessary in Mexico and elsewhere for silver ores, as at Kalgoorlie for telluride gold ores; but it was and is unnecessary for the majority of gold ores. Amalgamation was applied during the secondary crushing of Kalgoorlie ores because it was prac-

ticable and because grinding-pans were used. Elsewhere tube-mills were adopted, in which amalgamation treatment was not always feasible. In Mexico, on silver ore, amalgamation was only partly successful. Silver has a low specific gravity as compared with gold; it occurs mostly as the sulphide; amalgamation was not a logical procedure and was soon displaced by cyanidation. But no similar argument could be advanced in the case of the majority of gold ores; nevertheless, it is apparent that amalgamation has been abolished in many gold-recovery plants because of a desire to be up-to-date. There should be no question of antagonism between amalgamation and cyanidation in the treatment of gold ores. The experienced cyanide engineer will recognize that they are complementary processes, and that the ultimate metallurgical success of cyanidation, as judged by the amount of gold lost in the residue, will depend, to a large extent, on how great a proportion of the gold has been recovered by amalgamation before cyanidation is commenced. In a recent discussion on metallurgical methods in relation to gold production we cited an instance in which the average residue from a plant on the Witwatersrand contained 0.000046% of gold. To the publication of such a figure many will demur, affirming that the Rand ores are exceptionally amenable to amalgamation; but such is far from being the case. Comparatively fine grinding is needed; the metallurgists of the Rand realize that as much as possible of the work of gold recovery must be done before cyanidation is commenced; for the amount of gold in the residue after cyanide treatment is, to a great extent, proportionate to the amount of gold in the tailing coming from the amalgamation plant. If further proof of the utility of amalgamation be needed, it can be obtained nearer home. The excellent work at the Homestake, in South Dakota, is an example of exact precision in chemical manipulation on a large scale. The ore is first amalgamated to extract the coarse gold and thereby to diminish the subsequent cost of chemical treatment by cyanide; it is thoroughly washed during milling, and lime is added to counteract soluble refractories, as well as to assist coagulation and settlement. In Ontario, at the Dome mine, equally interesting results have been obtained by cyanidation after efficient amalgamation, by which a loss of only 0.000015% of gold in the residue was reported—under 10 cents per ton. Both these two results were obtained on comparatively low-grade ore. That of the Homestake averages about \$3.50 per ton; the Dome ore is worth a little over \$4 in assay-value. The need for amalgamation in the case of an ore of much higher grade is exemplified in the case of the Mysore mine, in India, where the material treated averaged \$12.84 in gold during 1920, and the residue was about 20 cents, thus indicating an extraction of 98.4%. Here again, however, it is obvious that the low final residue was due largely to the comparatively small amount of gold in the pulp going to the cyanide plant; for the policy of the company's engineers has been to reduce the grade as much as possible by amalgamation before cyanidation is com-

menceed. In this instance 89.7% of the gold is obtained by amalgamation, leaving only \$1.89 per ton for cyanide treatment, by which the loss is brought down to only 20 cents per ton.

There are instances where amalgamation is technically impracticable; in some cases its adoption is economically inadvisable, because of the danger of theft. But gold is always gold and always heavy. Amalgamation, as Mr. Crosse remarks, represents ready cash; cyanidation means deferred payment; or, to change the simile, the older process is the right barrel of the metallurgical shotgun; if the first shot fails, the sportsman uses the choke-bore of the left barrel to overtake the escaping game. The two processes must go hand in hand, for they are complementary, the success of the entire operation being dependent on the efficiency of cyanidation, and that in turn being dependent on the efficiency of amalgamation. In these days of intensive search for something new, one is inclined to undervalue the well-tried aids to success. The scientific application of amalgamation is just as pertinent a study today as it should have been before the invention of the cyanide process. In conjunction with cyanidation it is the hope of a waning gold industry; the combination of the two processes will permit the exploitation of low-grade deposits, as well as the expansion of the reserves in high-grade mines. A procedure that involves the slining or hammering of coarse gold, in an effort to make it soluble in cyanide solution, should be displaced by one that recognizes the fact that gold obtained by amalgamation is ready cash, and better in the safe than on the books.

The Use of Metals

At a time like this when the metal markets are in a state of acute depression it may be well to remind the pessimists among those engaged in mining that the present condition of affairs is temporary. Some people are talking and acting as if the world were about to return to the stone age and dispense with the use of metals, and as if therefore mining as an industry were destined to fall into irretrievable decay. They remind us of a child that, standing on the beach, imagines that the ocean is about to dry up because the tide is on the ebb. The sand is bared, the rocks are exposed, the pools are emptied; it looks as if the springs of the everlasting deep had failed. To a grown man the periodic rise and fall of the waters is a familiar phenomenon; even if he be but vaguely informed concerning the attraction of the moon and sun, he knows, from past observation and experience, that as surely as the waters recede so surely they will return. He is not frightened, as the child is; he counts confidently on the incoming tide at its appointed season. Some of our friends are childlike in their mental attitude toward the present depression. They say that "the bottom has been knocked out of mining" and they fail to see anything but gloom, as if a thick fog had fallen upon the sea, so that the turn of the tide was not even surmised. Any man of adult age, provided his memory be not

atrophied and his powers of observation paralyzed, will know, from past experience, that there is "a tide in the affairs of men", and that a period of excessive prosperity is followed by a period of excessive depression, as surely as there is a balance in Nature. During the War the mining industry of this country benefited enormously from the abnormal demand for the metals consequent upon the needs of warfare on a colossal scale; unfortunately the great increase of production that accompanied the abnormal demand was allowed to continue even after everybody knew that the War was at an end and that the excessive consumption must cease shortly. For example, the closing of the copper mines and the curtailment of the zinc output were belated; these steps to restore the balance of supply and demand should have been taken immediately after the Armistice. They were postponed for more than two years, so that an enormous surplus of metals was accumulated. The leaders of the industry ignored the fact that the disorganization in Europe and the failure of the United States to make peace with the Central powers precluded the disposal of our metallic output to many European customers, including some of those with whom we had done a great deal of business before 1914. Now, however, production has been severely curtailed, a legal end has been put to our state of war, our customers in Europe are beginning to organize themselves for new business, and the great surplus of metals in this country is diminishing. Some months of comparative inactivity are still ahead of us, because those in control of our big mining enterprises deem it wise to deplete stocks until a vigorous demand comes from the consumers. It will come. "Man does not live by bread alone", he needs metals also. Civilized man requires food first, then clothes, and when these primary necessities have been satisfied he calls for metals. Our material civilization has a metallic foundation. Unless the whole world returns to political and industrial chaos, it will renew its insistent demand for the miner's products. The smaller the quantity of metals that is used now, the larger the quantity that will be needed shortly. The miner's turn is coming again soon. Sit tight, gentlemen.

Meanwhile, we venture to repeat our advice to the younger men—and it may appeal to some of the seniors as well: to use the time of inaction to some purpose. "All things come to him who knows how to wait", not to him who simply waits in the expectation of something coming his way. The short period of inaction that may be ahead of many of us should not be frittered away aimlessly. Take the opportunity to study some technical subject or to engage in special research. If you can afford it, travel. Go to some neighboring mining centre and make yourself familiar with the ore deposits, the mining practice, or the metallurgical methods of another district. If you need a holiday, play golf or go fishing; but whatever you do, make the most of the enforced leisure; play hard or work hard, but do not fool away the time, for the period of intense activity and expansive production that is surely coming will find full scope for all those who are prepared to take their part.

Concentration of the Ore

By Arthur B. Parsons

As soon as it was definitely decided, in 1906, to build the milling and smelting plants at McGill's ranch, surveys were begun; and actual construction was started early in 1907, some months after the completion of the Nevada Northern railroad from Cobre on the Southern Pacific. The original design of the concentrator provided for ten units, each divided into two sections, having a capacity of 500 tons per 24 hours, or a total rated capacity of 5000 tons of ore per day. Only the four southern units were completed, for the reason that it was found possible to obtain a much greater capacity than had been expected. The records show that between 8000 and 9000 tons of ore per day was being treated in seven operating sections in June 1910, just two years after the first unit was put in operation; and since then as much as 4000 tons has been concentrated in a single unit, or eight times the quantity originally planned.

Among the principal characteristics of the ore that appeal to the millman are its unusual softness, which makes it easy to crush; and the large proportion of kaolin and talcose minerals it contains. These cause some difficulty in handling the dry ore in bins and chutes, and also make settling of the slimed pulp exceptionally slow. While the ore from the Ruth mine is a comparatively clean sulphide, containing chalcocite, chalcopyrite, and pyrite, there is a considerable admixture of oxide and carbonate minerals in the ore from the steam-shovel pits. The presence of these minerals increases the difficulty of concentrating, and has had an especially important bearing on the development of a successful scheme for employing froth-flotation. The proportion of pyrite in the ore has a direct effect on the grade of the concentrate, it being generally desirable to keep the proportion of pyrite in the concentrate, sent to the smelter, as low as possible.

EARLY OPERATIONS. An interesting description of the early operations of the plant appears in an unsigned article published in 'Mines and Methods' for September 1909. This publication will be remembered as the late Col. E. A. Wall's personal journal; although launched as a medium through which he might ventilate his ideas respecting the Utah Copper project and D. C. Jackling, it contained during its brief career many articles of considerable technical value. The accompanying flow-sheet of the concentrator, Fig. 1, is reproduced from 'Mines and Methods'. It is not entirely correct; for instance, the primary crushers were McCully gyratories, not Gates; and the classifiers were not "Richards vortex", but were a modification of that device, originated by

Pope Yeatman. However, the flow-sheet gives a general idea of the scheme of treatment. It is typical of the methods of concentration used at that time, and contrasts remarkably with the simple routing of the ore in the present treatment by flotation. It will be noted that the material from the crushed-ore storage-bin is wetted immediately, preparatory to passage through a series of wet rolls with interposed trommels, the last of which returns, for further crushing, everything that fails to pass a $\frac{3}{16}$ -in. screen. This fine product is divided into two sizes by a 2-mm. screen; the undersize is classified and concentrated on Wilfley tables, whereas the coarse is re-ground along with the middlings and part of the tailings from the first Wilfleys, together with oversize from 30-mesh Callow screens, which follow the re-grinding machines. The result is that nothing is allowed to escape as tailing that has not been ground to pass 30-mesh. Undersize from the Callow screens is classified in a four-compartment spitzkasten, tabled on Wilfleys, and finally concentrated on vanners. For the first product of the spitzkasten corrugated vanner-belts are used; for the remainder, smooth belts. Callow tanks are used to thicken the table-feed.

The original design called for four 6-ft. Huntington mills as re-grinding machines for each section. However, before the construction of the last unit was completed, it was decided to use Garfield Chilean mills instead of Huntingtons. In spite of some increase in the slime produced, the capacity and convenience of the Chileans so far surpassed that of the Huntingtons that one Chilean was added to the early sections, while three were added to do all the re-grinding in each of the new sections. This would indicate that one Chilean would crush approximately the same tonnage as two Huntingtons of the same nominal diameter. The maintenance of a full feed, of proper dilution, and the careful adjustment of the plows will do much toward diminishing the amount of slime produced.

In the 'Mining and Scientific Press' of June 11, 1910, under Staff Correspondence, the following summary of operations is given: "It is stated that as high as 10,500 tons have been put through in 24 hours. With only seven sections now in operation the plant already handles between 8000 and 9000 tons per day. The ore is first passed through McCully gyratory crushers. There are 8 sets of 15 by 36-in. coarse rolls, and 16 sets of 14 by 36-in. fine rolls, Allis-Chalmers type. In each section are 68 Wilfley tables and 48 Allis-Chalmers vanners; four elevators, 12-ply, 20-in.; four 6-ft. Huntington mills and one Gar-

field Chilean mill [this doubtless refers to the original sections]; eight Steptoe classifiers [an improvement on the so-called Yeatman classifier]; eight 2-mm. revolving screens and two $\frac{1}{2}$ -mm. screens for dewatering; and 46 Callow tanks. An important change in the practice consists in taking out No. 1 trommel, which was formerly used to take out an undersize product before wet-crushing in coarse rolls. This trommel having been taken out, the entire feed of the mill passes direct to the coarse rolls, which operate dry instead of wet as formerly. This change has served to increase the capacity, makes a steady feed possible, with no choking of the rolls. The change from wet to dry crushing, as applied to the coarse rolls only, and the installation of the Steptoe classifiers, are said to have resulted in adding 60% to the capacity of the mill. The process becomes a wet one after the pulp passes through the coarse rolls, of which there is one set to each section." I am informed that this statement of the increased capacity is accurate, the result, largely, of more uniform feeding to the rolls. It should be borne in mind that the ore is comparatively soft and is readily crushed.

COMPARISON OF STEPTOE AND GARFIELD SYSTEMS. During 1911 a number of Richards-Janey classifiers were installed and Section 3 was remodeled so that its flow-sheet conformed in a general way to that used at the concentrators of the Utah Copper Co. at Garfield. Allen H. Rogers made a series of tests in November of that year to compare the results obtainable by the two systems, namely, the 'Steptoe' and the 'Garfield'. Although both are almost obsolete today, the fact remains that the design of the newest section, which has not yet been put into regular operation, provides for the use of Garfield roughing-tables in conjunction with Wilfley tables and flotation-cells. The following paragraphs are abstracted from Mr. Rogers' interesting report.

"The essence of the Garfield system is the production of a low-grade concentrate on Garfield roughing-tables, which is afterward re-dressed on Wilfley tables, and the re-classification of the fine spigot product from the primary classifiers. The ore passing the 2-mm. trommels is delivered directly to Garfield tables. These make a rough concentrate while the tailings are delivered to the primary classifiers. The effect of the tables is to produce a higher-grade feed to the Wilfley finishing tables, so that the ratio of concentration is low, and the streak of concentrates is wide, thus permitting the production of a higher-grade product with lower insoluble than would be possible from the direct feed. The tailings from these Wilfleys, consisting of true middlings, are delivered to the re-grinders. The Garfield table should deliver to the concentrate end all free mineral except that of the finest sizes, while the tailings which are fed to the classifier consist of true middlings and tailings with a little fine free mineral. This material, when classified, yields from the first spigots coarse material containing no free mineral but which still contains enough occluded mineral to make worth while grinding. The product from the first two spigots, therefore, is fed directly to the

re-grinders. The finer spigots discharge the lighter particles consisting of clean gangue and very fine free mineral and these products are delivered to the secondary classifiers where they are still more closely classified, and then treated either on Garfield or Wilfley tables. The distinction of this flow-sheet is the production of the rough concentrate which is afterward re-dressed, and is particularly advantageous in the treatment of an ore, the ratio of concentration of which is high. In such cases where the proportion of concentrates from the ore is small, it is a great advantage to have a wide streak of concentrates on the tables making a finished product because the proportion of silica necessary to include with the concentrates in order to save all of the latter is much smaller than it is where the streak of concentrates is narrow. In a word, it increases the ratio of concentration without decreasing the recovery. This flow-sheet also aims more thoroughly to eliminate free mineral from the material requiring re-grinding, accomplishing this by what amounts to double classification, for the Garfield tables are, in effect, classifiers. Properly handled, it accomplishes this well, although, as operated during the tests, it did not show as good a result in this respect as Section 8, in which the Steptoe system is used. The disadvantage of the system is that it requires more equipment which occupies more space and requires more power and attention.

"In Section 8 [Steptoe flow-sheet] the ore passing through the 2-mm. trommels is delivered to the classifiers, the first three spigots of which deliver to Wilfley tables making finished concentrates. The middlings from the first-spigot tables is re-dressed and re-ground with the tailings from the same. The second- and third-spigot tables make middlings for re-grinding and tailings to waste. The foregoing middlings are classified and screened before being ground in order to eliminate fine free mineral. The Wilfley tables in this section are equipped with National rifles. This rifle differs from the Wilfley rifle in extending the full length of the table, and, along the line which would mark the end of the Wilfley rifles, each rifle has a wave, the effect of which is to subject the concentrates to a vaning motion, for in order to pass the wave, they are obliged to travel slightly up grade. The effect of these rifles is, apparently, to decrease the necessity for delicate adjustment of the table. It would appear, however, from observation, that they require more water, and that, where the feed is not closely classified, it is difficult to keep the very fine sand out of the concentrates.

"In theory, this flow-sheet aims to remove the free mineral before re-grinding, by direct concentration. The primary tables are fed with closely classified material and it is conceded that all gangue falling from the first spigot of the classifier merits re-grinding. From the second and third spigots, clean tailings are made, while the middlings from these tables are re-ground. The screening to which these are subjected before re-grinding is intended to remove any fine free mineral that they may contain. This is accomplished to a considerable extent."

Although the proportion of free mineral lost in the tailing was much higher in Section 3 than in Section 8, thereby suggesting that more careful attention to the operation of tables and classifiers might alter the final result, nevertheless, Section 8, using the Steptoe flow-sheet, effected a better recovery of copper, had greater capacity, and produced an equally clean tailing. Fewer machines were required and the cost of operation and maintenance was probably lower.

One section of the mill followed the Steptoe flow-sheet, but differed from Section 8 in that two sets of rolls, 35 in. by 16 in., running at 160 r.p.m. with the shells touching, did the re-grinding instead of three 6-ft. Garfield Chilean mills. A comparative test was made to determine the respective merits of the re-grinders in these two sections with Huntington mills used in a third section. The following figures are interesting:

	Huntington mills	Rolls	Chilean mills
Ore treated per 24 hours, tons.....	741	519	421
Proportion reduced through 30-mesh, %.....	27.9	26.9	55.8
Ore reduced through 30-mesh, per 24 hr., tons	201	140	235
Power absorbed, hp.....	104	93	95
Ore reduced through 30-mesh per hp.-day, tons	1.93	2.22	2.47
Increase in -200-mesh material, %.....	7.4	10.1	16.6
-200-mesh material produced per day, tons..	51.8	52.4	69.9
Ore reduced through 30-mesh while producing 1 ton of -200-mesh material, tons.....	3.69	2.67	3.36

Mr. Rogers comments as follows: "These figures show that the rolls produce more slime than the Chilean mills, a result that is entirely at variance with the usual conception. Calculations based on the third series of samples, however, show a similar result. It is possible that the method of driving the rolls, namely, by but one pulley, may account to some extent for this showing, and before reaching this conclusion fully, more tests should be made.

"It will also be noted from the figures that the Chilean mills show advantage in point of power absorbed, for they show the highest tonnage through 30-mesh per horsepower-day. In respect to repair cost on the different machines, no data exist regarding the rolls. Of the other two, the Huntington mills are more expensive to maintain while as between the Chilean mills and the rolls, the question can be determined only by keeping account of this cost over a long period, and this should be done. Altogether, as far as data go at present, the comparison results in favor of the Chilean mills."

The following statistics pertain to a 13-month period ending October 31, 1911:

Ore milled, tons	2,920,711
Average per day (396 days), tons.....	7376
Proportion of total capacity operated, %.....	79.5
Power consumed per ton of ore, hp.....	0.47
Water consumed per ton of ore, tons.....	7.7
Ore concentrated per ton (including vanners), per day, tons..	10.05
Copper contained, per ton of ore, lb.....	35.9
Copper recovered, per ton of ore, lb.....	24.2
Average recovery of copper, %.....	67.48
Ratio of concentration	11.31
Number employees on operation.....	469
Number employees on repairs.....	141
Cost of milling, cents.....	45.2

ALTERATIONS IN THE PLANT. In 1915 the results in the mill were the best in the history of the plant up to this time. An important feature was the increased ratio of concentration which was 7.18 in 1915 as against 6.05 in 1914. This ratio had been gradually diminish-

ing each year prior to 1915 partly because of the increasing proportion of pyrite in the ore being milled. The following figures show the average results obtained in the concentrator during 1915.

Ore milled (dry), tons	3,081,520
Assay of heads, copper, %.....	1.54
Extraction, copper, %	70.18
Ratio of concentration	7.18
Assay of heads, gold, oz.....	0.017
Assay of heads, silver, oz.....	0.042
Extraction, gold, %	49.47
Extraction, silver, %	51.34
Assay of concentrate, copper, %.....	7.77
Value of gold and silver recovered per ton, cents.....	18.50

During that year plans were made for, and work was started on, a number of alterations and additions to the plant and equipment for the purpose of obtaining added

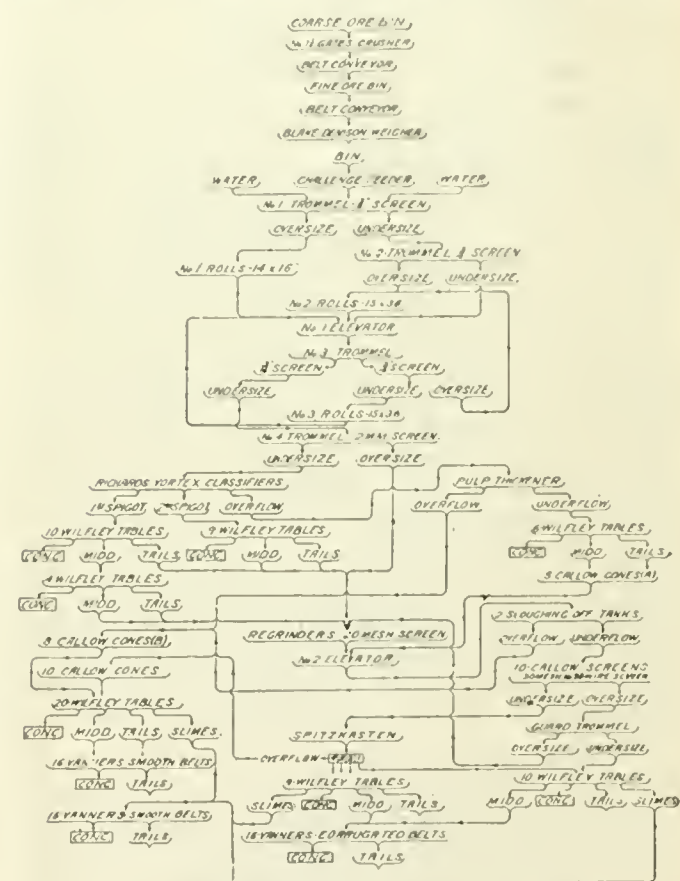

FIG. 1. FLOW-SHEET OF CONCENTRATOR IN 1909

capacity and increased efficiency. The most important measures were (1) the installation of double-decked concentrating tables to replace the old ones that had become overloaded, due to increased tonnage; (2) the substitution of tube-mills for Chilean and Huntington mills in the re-grinding department, thereby effecting economies in operation and adding to the capacity; (3) the construction of a new coarse-crushing plant.

The arrangement of the old crushing plant was unique; it has been the subject of much unfavorable criticism. It seems that when the mill was originally built the plan was to size the ore, in which there was a large proportion of fine material, at the mines; this, in fact, was done with the ore from the Veteran mine, but it was never found practicable for the steam-shovel ore.

The two sizes were to be shipped in separate standard railroad-cars to the concentrator; the cars carrying the finer material were to be dumped directly into the fine-ore bins that extend the full length of the plant on the uppermost terrace of the mill-site, leaving only the oversize mine-product to pass through the coarse-crushing department.

Having determined that the main railroad-track should surmount the ore-bin, it was necessary to provide an approach. Just why the entire plant could not have been moved a short distance to a more appropriate site does not seem clear; the fact remains, however, that the approach as constructed consisted of a huge double-track trestle, extending from the south end of the mill to an earthen abutment 1672 ft. distant. Of the total length, 460 ft. nearest the mill-building is of steel, and the remainder of wood, the maximum height being 109 ft. It cost \$250,000. The steel portion supported the coarse-ore bin, beneath which was the coarse-crushing machinery, and the sampling-mill for the smelter. As a matter of fact the plan for sizing at the mine, in furtherance of which this trestle was built, was abandoned, but under any circumstances the decision to build the trestle seems to have been a serious engineering blunder.

Owing probably to the continued strain imposed by braking heavy trains, the structure was several inches out of plumb in 1915 and the wooden trestle was condemned as unsafe. It is now being torn down, the material providing excellent timber for the underground work in the Ruth mine. Although the crushing plant had successfully handled several times the quantity of ore for which it originally had been designed, a particularly large force of operators and mechanics was required to operate and maintain the machinery. Accordingly plans were made for an entirely new plant designed in accord with the most modern ideas and recent practice. It is well worth describing in some detail.

THE NEW CRUSHING PLANT. The bin is directly behind the mill-structure proper, the centre lines almost coinciding. The railroad track leaves the old line near the trestle abutment and follows the contour of the hill. A train of cars from the mine first passes over a Fairbanks standard track-scale equipped with a Streeter-Amet automatic weight-recorder. Each car in a train traveling at three miles per hour is weighed automatically and the weight stamped on a permanent record, with no chance for error through human fallibility. The train is then switched back to the return-side of a loop conveniently arranged, on a track surmounting the coarse-ore bin. This bin is 288 ft. long, 20 ft. wide, and 14 ft. deep, with a capacity of 5000 tons. On each side of the single track is a horizontal grizzly made of 70-lb. rail spaced 18 in. with the ball down. This leaves a 14-in. opening. Boulders that do not pass the grizzly are broken with hand-hammers or with dynamite. Inglesby side-dump railway cars, of 60-ton capacity, are dumped easily and are pronounced to be first-class in every way.

A novel feature is the use of compressed air to loosen

the ore, which has a decided tendency to pack in the bin, owing to the clay-like character of much of the material. The discharge hoppers are in the centre of the bin, but so coherent is the ore, even when comparatively dry, that it forms almost vertical walls above the openings in the bottom. A great deal of work with bars and shovels has been avoided since the introduction of compressed-air pipes. Two-inch pipe-lines fitted with individual valves branch from a 6-in. header. The outlet of each is an open 45° L that looks downward and toward the centre of the bin at a point three feet above, and three feet back from, the discharge-opening. There are two rows of these, one along each side of the hoppers. It is astonishing how effectively the ore can be loosened by a short blast from one of these pipes. Previously 10 men per shift were required for this service.

The bottom of the bin, which is divided into two sections symmetrical about the centre line, is provided with 24 steel hoppers, directly beneath which are 24 steel apron-feeders 60 in. wide by 8 ft. 9 in. between the centres of head and tail sprocket-shafts. With the exception of one in each half, all the feeders point toward the centre line of the plant. The two excepted are placed back-to-back at the centre line, so that each faces the second feeder on its side. These four are high-speed feeders. The ten remaining in each half discharge onto a steel-pan conveyor, 60 in. wide and 118 ft. between head and tail sprocket-shafts. Each pan-conveyor discharges onto a traveling grizzly, 60 in. wide and 19 ft. 6 in. long, set transversely to the pan-conveyors. The grizzly-openings are about 3½ by 60 in. The two high-speed feeders in each half discharge directly onto their respective traveling grizzlies. The feeders are driven through bevel gears and eccentrics from line-shafts, at a speed of 2.5 ft. per minute, giving a maximum capacity of about 125 tons per feeder per hour. The individual feeders are controlled by separate pawls operated by the eccentrics. The four high-speed feeders have a capacity of 500 tons each per hour; accordingly it is possible when conditions are favorable, to dump all cars over the centre of the bin and to supply the entire plant by these four feeders, with the minimum movement of the ore, and use of machinery.

The oversize from each traveling grizzly (see accompanying illustration) is discharged to a No. 8 McCully gyratory crusher set to crush to about 3½ in. This makes a 4 to 1 reduction from the maximum oversize of 14 in. The crusher is driven by a 100-hp. motor at 425 r.p.m., direct-connected to the pinion-shaft of the crusher by a Nuttall flexible spring coupling. The pinion-shaft was cut off about 12 in. outside the main double bearing and no outboard bearing was used. This is thought to be the first time this plan has been tried, but no trouble has resulted. It saves belting and space, and is a measure for safety.

The discharge from the crushers joins the undersize from the traveling grizzly. This material is picked up on an incline belt-conveyor 42 in. wide, with 120-ft. centres, set at an angle of 19° 20', and traveling 250 ft.

per minute. Each conveyor discharges onto a stationary inclined screen 6 ft. wide by 14 ft. long. The screen-frame is suspended over the undersize-chute on adjustable eye-bolts so that the most effective screening-angle can be obtained readily. There appears to be a critical angle for stationary screens, depending on the material screened and method of feeding. The oversize from each screen passes to a set of 72-in. by 20-in. Garfield rolls of the Alaskan type, having both drive-pulleys on the same side with an outboard bearing carrying the shaft-extension of the master roll. Each set of rolls is driven by belts from a line-shaft, which in turn is driven directly by a 150-hp. motor. The rolls are set to a $\frac{3}{8}$ -in. opening, making a reduction of 4:1 from a maximum oversize

screen. This procedure will take much of the burden from the ball-mills and will permit efficient grinding in a single stage. The accompanying drawing, Fig. 2, shows clearly the arrangement of the new equipment.

The two conveyors discharge the material at a point that is both the longitudinal and the transverse centre of the main fine-ore bins. From this point two horizontal tripper-conveyors distribute the ore to the storage-bins, which have a capacity of 30,000 tons. Prior to the remodeling of the plant about 16% of the material delivered to the storage-bins was coarser than $\frac{1}{2}$ in., while 25% would pass a 48-mesh screen.

The total connected load is about 860 hp. With the exception of the feeders each machine in the plant is

FIG. 2. PLAN AND SECTION OF THE COARSE-CRUSHING PLANT AS IT WILL BE WHEN ALTERATIONS HAVE BEEN COMPLETED

of $3\frac{1}{2}$ in. The product from each set of rolls joins the undersize from its respective screen, and this material, the final product of the coarse-crushing plant, is carried by one of two inclined conveyors, 42 in. wide, with 270-ft. centres, set at an angle of about 16° , and running 275 ft. per minute. It is significant of the rapid progress being made in the art of ore-dressing that an important change is already under way in this plant, only about three years old. The stationary screens are to be supplemented by 6-mesh Mitchell vibrating screens. The oversize will be sent through the present rolls; this product will be screened on secondary Mitchell screens, the oversize from which will be re-crushed in a newly installed set of fine rolls. The product from this set will join the stream of ore to the first screen, while the undersize from both screens will go to the 270-ft. inclined conveyors, thus forming a closed circuit from which nothing escapes but material that has passed through a 6-mesh

driven by an individual motor. The first reduction, wherever gears enter into the driving mechanism, is made by belt or chain from the motor. Starting-boxes for all machines are set on either side of a control-booth from which an operator can see the entire plant. This booth is shown in one of the accompanying photographs. For emergencies two master-switches are provided in the booth, one for each half of the plant. These switches are cut into the main service-leads coming from the substation, so that power can be cut-off from the entire plant instantaneously. Each motor is provided with an overload relay and a low-voltage release. The design of the plant provides that each machine has a capacity slightly greater than that immediately preceding it. This allows the maximum feed without the possibility of chokes in the subsequent operations.

The plant is probably the first of its class in which material is elevated entirely by means of inclined belt-

conveyors to the complete exclusion of elevators. George C. Riser, superintendent of the concentrator, points out the following faults to be found with elevators: (1) The great expense of maintenance and renewal. In contrast the life of conveyors is exceptionally long. (2) The delay to operations. The clayey character of the ore is so

Adamson company and is thoroughly standardized. All belts are 42 in. wide, of 8-ply construction, with a $\frac{1}{2}$ -in. rubber surface. The idlers are troughed, with ball-bearings, while the return idlers are equipped with Hyatt roller-bearings. All chutes are made of sheet-steel and are lined with cast-iron or boiler-plate. There are no gates or chute-doors in the plant, the flow of ore being stopped by altering the slope until the angle of repose is reached. I am indebted to Curtis Lindley, who participated in the design and erection of the new crushing-plant, for his kindness in supplying me with many of the details given in this description.

Returning to the point from which I digressed to describe the new crushing-plant: The various changes made in the equipment and flow-sheet have for their chief object an increase in tonnage treated. The statistics that follow summarize the results obtained during the period of three years.

	1916	1917	1918
Tons treated per day (running time)	11,531	12,663	13,051
Recovery, %	73.87	73.08	67.28
Heading, copper, %	1.63	1.46	1.50
Heading, copper, %, as oxide and carbonate	0.13	0.14	0.17

The decrease in recovery in 1918 is accounted for principally by the inability to obtain competent and experienced mill-operators; government service during the War drew heavily upon the personnel of the organization. Another factor was an increase in the proportion of oxide and carbonate copper compounds in the ore, which militated against high extraction.

CONCENTRATION BY FLOTATION. Experiments had been in progress since 1914 for investigating the advantage that might accrue from the use of froth-flotation. Tailing from the vanners had been floated with some recovery of copper, and flotation equipment had been installed in the main plant. In Fig. 3 is seen the flow-sheet of Section 7 in 1919; this is typical of the treatment, used prior to the recent shut-down, in the sections that are not yet remodeled. This shows the flotation of

the slime overflow from the Steptoe classifiers and of a portion of the vanner tailings, but the general principles of the 'Steptoe' flow-sheet survive. For the most part, however, the results of flotation were unsatisfactory, especially on the mixed ore. The high content of alumina (about 14%) was detrimental, as was also the presence of oxidized minerals. However, in 1919, after the discovery of 'xylydine' as a solvent for 'X-

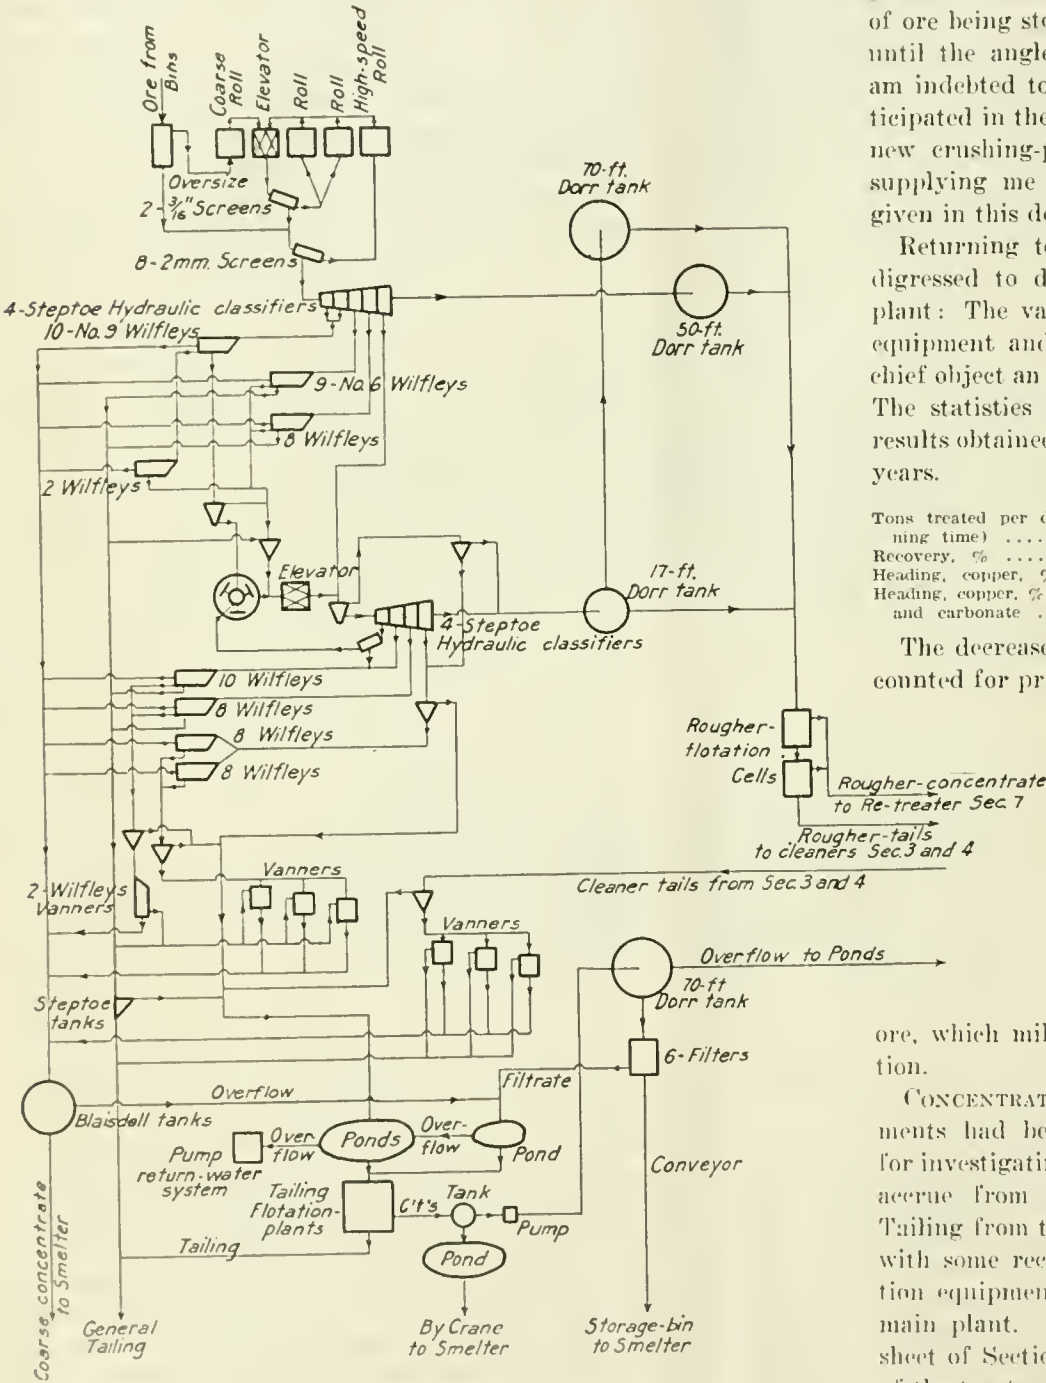

FIG. 3. FLOW-SHEET OF SECTION 7 IN 1919

pronounced that elevator-buckets cannot be kept clean. The ore accumulates in the buckets until the capacity of the elevator is reduced to the point where it must be shut-down. The time required to dig out the buckets may amount to hours, and may represent a large proportion of the possible operating time. The entire plant is designed to facilitate the handling of this sticky ore. The conveying equipment is supplied by the Stephens-

cake', a scheme of treatment was developed that far surpassed my results obtained prior to that time. After exhaustive experimental work, plans were completed for the remodeling of Section 3 with flotation as the essential step in concentration. A second design was developed for Section 4; the difference is that here table-concentration of the 6-mesh ore precedes ball-mill grinding for flotation.

At the time the plant was shut-down, on April 2, 1921, Section 3 and three-fourths of Section 4 were remodeled and in operation; I shall first describe briefly the treatment as practised in Section 3. The original fine-ore bin had a flat bottom 30 ft. 6 in. from front to back, the ore passed through hand-operated basket-gates onto a conveyor, which discharged into a small auxiliary bin, from which it was supplied to the rolls by Challenge feeders. In remodeling this section a steeply pitched hoppers bottom has been constructed to replace the old bin-floor and a series of rotary feeders, one for each ball-mill, has been installed. The rotary feeder is a pulley 5 ft. in diam. with a 36-in. face, operated by a dog connected with an eccentric. A rack-and-pinion gate provides for the adjustment of the aperture above the face of the pulley, through which the ore flows. Compressed-air pipes similar to those used in the receiving-bins of the coarse-crushing plant have been provided to facilitate the constant flow of the ore.

In Section 3, ore from the fine-ore bin is fed directly to 30-in. by 8-ft. Hardinge ball-mills, driven through herringbone gears by 125-hp. motors, and arranged in closed circuit with 6-ft. Dorr duplex classifiers. The Hardinge mills are fed with 3-in. balls, cast in the plant foundry; each grinds 450 to 500 tons per day and supplies three rows of flotation-cells. The flotation feed, overflowing from the classifier, passes through a punched screen for the removal of wood-pulp and other debris. A simple detail, but one that has an important bearing on the efficiency of flotation, is the inclining of these screens to an almost horizontal, instead of a vertical, position. The result is a constantly uniform feed instead of a periodical deluge, which would otherwise follow when the operator cleaned the screen. Uniformity of feed is essential to good flotation.

The rougher-cell is a trough, 30 in. wide and 20 ft. long, with the bottom sloping $\frac{1}{2}$ in. per foot. These are arranged in pairs with a common launder running lengthwise between the two, and with an additional launder on the outer side of each, to receive the froth. The accompanying illustration gives a good idea of the general appearance of the cells. The bottom of the cells is fitted with filter-mats, 15 in. by 30 in., composed of a cast-iron pan covered with four-ply twill furnished by the Filter Fabrics Co. Individual air-pipes extend from the six-inch header placed at a convenient distance above the cell, through the pulp to the mats, where connection is made by a special lock-nut. The air-pressure is usually maintained at 5 lb. per sq. in., while the dilution of the pulp is approximately 3:1, water to solid. The pulp-level is regulated by a weir-overflow at the effluent end of the cell

where a vertical baffle prevents the froth from escaping. Froth from the roughers is re-floated in a cleaner of the same design.

The concentrate from the cleaners flows to three 60-ft. Dorr thickening-tanks. The underflow, having a consistence of $1\frac{1}{2}$:1, water to solid, is filtered by four Oliver and two Portland filters, all 12 ft. by 12 ft., producing a cake averaging 15% moisture.

The flotation tailing is concentrated on No. 5 Wilfley tables. The table-concentrate joins that from the flota-

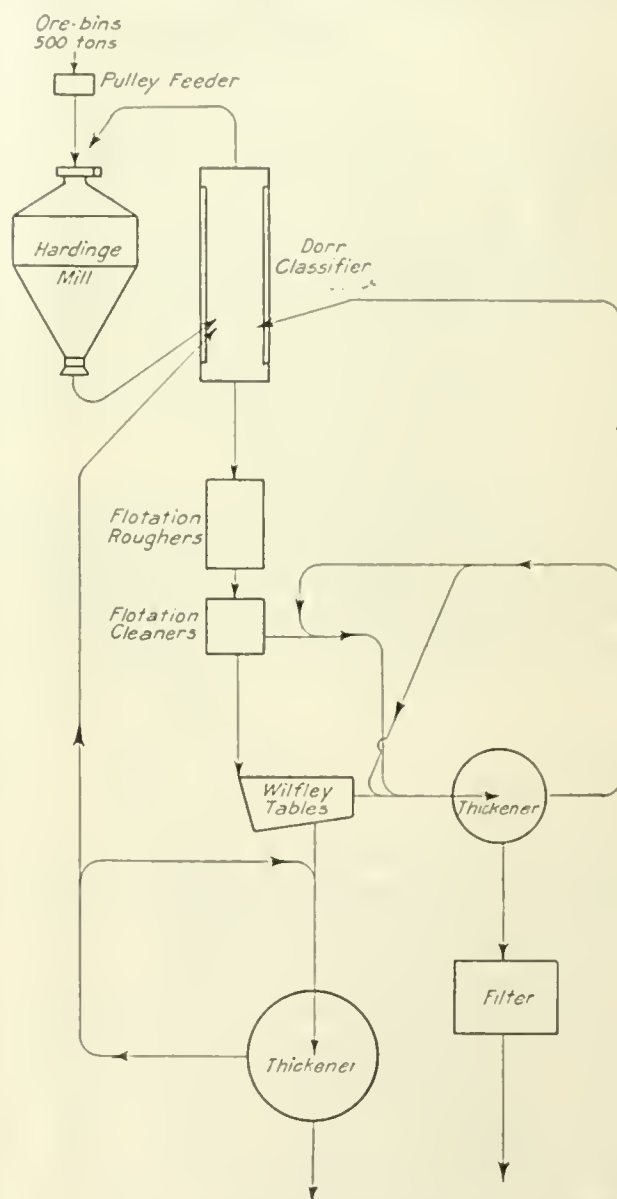

FIG. 4. PRESENT FLOW-SHEET OF SECTION 3

tion-cells as it enters the thickener. Being somewhat coarser than the froth-concentrate and having been freed of any coating of oil, it hastens the settling and permits a thicker pulp to be drawn off than otherwise would be possible. It is likewise beneficial in filtering; it makes the cake more porous, and therefore dryer.

It may be noted that the return water from the thickener and filter is sent directly to the classifier instead of being used to wet the feed to the ball-mill. Another in-

teresting point is the feeding of all flotative reagents through a small pipe that extends several inches beneath the quiet surface of the pulp at the head of the rougher-cell, where the first mat has been removed so that there is no agitation whatever at the point where the reagents are introduced. This procedure is possible because of the solubility of the flotative reagents.

Section 4 differs from No. 3 in several respects, as may be seen by examining the accompanying flow-sheets (Fig. 4 and 5). The ore from the fine bins, all of which here-

conveyors, which discharge into standard-gauge cars on the same track as those that receive the cake from the Oliver filters. The overflow goes to the thickeners that receive the flotation, and secondary-table, concentrates. One feature of the treatment in both of these sections is its extreme simplicity. When adjustments are once made the minimum of attention by the millman is necessary, the entire operation being as nearly automatic as possible. One of Mr. Riser's theories is that simplicity is synonymous with efficiency and economy.

Table I—Results Obtained in the Remodeled Sections During Early Part of 1921

Month	Tons milled	Heading Copper, %	Concentrate			Tailing Copper, %	Copper in form of oxide and carbonate		Ratio of concentration, %	Indicated extraction, %
			Copper, %	Insoluble, %	Iron, %		Heading, %	Tailing, %		
January	100,569	1.566	10.45	28.8	23.9	0.364	0.13	0.04	8.4	79.4
February	119,547	1.472	11.96	30.0	23.5	0.284	0.13	0.02	9.8	82.7
March	124,483	1.472	14.88	25.1	24.6	0.280	0.06	0.03	12.1	82.7
April	7,176	1.506	13.46	0.202	10.8	82.3
Average	351,802	1.499	12.59	27.3	23.5	0.306	0.10	0.03	10.3	81.6

after will have been crushed to pass a 6-mesh screen in the coarse-crushing plant, will go directly to Garfield tables; the product will be cleaned on No. 5 Wilfleys; and the tailing will flow to four Dorr classifiers, the sand from which will feed four cylindrical ball-mills, the overflow going to the flotation department. The remaining treatment will be the same as Section 3.

It will be observed that a comparatively coarse table-concentrate is prepared in this section. One important reason for this provision is the desirability of supplying the smelter with a certain proportion of coarse concentrate. While it is true that this rougher table-concentrate has a higher iron content and is lower in copper

The accompanying tables show the results obtained in the remodeled sections of the mill during 1921 prior to the shut-down in April. Table I gives details and averages for the first four months, whereas the others deal with the month of March only.

The following figures, comparing the work done in 1911, 1915, and 1921, are typical of three different periods in the history of operations.

Year	Mill heading, copper, %	Ratio of concentration	Concentrate, copper, %	Extraction, %
1911	1.79	11.31	14.2	67.48
1915	1.54	7.18	7.77	70.18
1921	1.49	10.3	12.59	81.6

The most significant feature is the combination of high

Table II—Composite Analyses—Month of March 1921

	Gold, oz.		Silver, oz.		Copper, %	Silica, %	Iron, %	Lime, %	Alumina, %	Sulphur, %	Copper in form of oxide and carbonate, %
Heading	0.015		0.055		1.472	67.2	3.9	0.5	10.6	3.2	0.10
Total concentrate	0.106		0.372		14.880	20.0	24.6	0.2	5.1	29.0	0.34
Final tailing	0.005		0.027		0.280	71.6	2.0	..	14.6	0.86	0.03

than that obtained from flotation, this disadvantage is more than offset by the simplified handling in the roasters at the smelter. This will be mentioned in a subsequent article describing the smelting operations.

An interesting innovation is a filtering or dewatering arrangement on the classifiers. The coarse concentrate from the primary tables goes to a specially built Dorr machine, the inclined floor of which, above the water-level, is provided with a filter-bottom covered with a bed of coarse concentrate, 4 in. thick. Beneath is a chamber connected with a vacuum-pump; the suction removes most of the water as the concentrate is advanced by the rakes. The dewatered product falls onto horizontal belt-

extraction, high ratio of concentration, and the production of high-grade concentrate in 1921. Ten years before it was the practice to maintain the grade of the concentrate and the ratio of concentration at the expense of good recovery; in 1915 the concentrating ratio and the grade of the product were sacrificed to get a higher extraction from ore that was not only leaner in copper but less desirable because of the higher proportion of pyrite and oxidized copper minerals in its composition. The ore being milled today differs but little from that of 1915; but improved methods of concentration, including flotation with soluble frothing reagents, has made better results possible.

Table III—Screen Analyses—Month of March 1921

Mesh	Flotation concentrate			Table-concentrate			Final tailing		
	Weight, %	Copper, %	Per cent of total	Weight, %	Copper, %	Per cent of total	Weight, %	Copper, %	Per cent of total

Licensing of Engineers

The following is the report of the committee appointed by the Mining and Metallurgical Society of America to consider the question of licensing engineers:

August 11, 1921.

To the Members of the Council

M. M. S. A.

Dear Sirs:

In accordance with the instructions which your Committee on Licensing of Mining Engineers received from President Spurr, we beg to submit to you the following report.

128 letters have been received in response to the letter of the President asking for an expression of opinion. The responses have been classified as follows:

"A"—Unconditionally opposed	81
"B"—Opposed on general principles but would favor uniform State laws with reciprocity or general Federal law	12
"C"—Opposed, but would accept licensing as a matter of expediency and would join in attempting to steer legislation	4
Total opposed	97
"D"—In favor, conditionally	16
"E"—In favor, unconditionally	5
Total in favor	21
"F"—Doubtful	8
"G"—No opinion	2
	10

The difference between B and C and D is that B and C are opposed on principle while D favor the principle but wish to avoid the annoyance and expense entailed in individual State licenses.

These unconditionally in favor of licensing base their attitude on the desire for higher professional standing and better protection of the public.

Obviously, however, these are matters as to which those of the opposition are equally concerned, even though their solicitude may not be voiced, or may be but inferentially or negatively expressed.

It is also to be observed that those conditionally favorable must be considered as virtually of the opposition, in view of the weight of negative opinion bearing on the conditions stipulated.

Briefly, the point of view of this opposition is to the following effect:

Licensing would neither improve nor safeguard professional standing, partly because professional qualifications could not be adequately formulated in such a law, and partly because of probable miscarriage in its administration.

In determining professional qualifications it is necessary to take into account, not only the technical ability called for by the work in contemplation, but also character and the lay attributes required of the engineer in that connection. Often, technical ability is secondary to the other factors, and the matter of qualifications a ques-

tion of something inherent or earnest rather than of something acquired—something that no conceivable licensing system could measure.

Administration would not only be confronted with difficulties, due to the considerations just mentioned, but, in all probability, would suffer from the play of politics, as well as from undue regard for local interest.

Consequently, it is widely held that licensing would be of no real advantage to the profession; that, even with State reciprocity, it would involve useless expense and hardship; and that it could not possibly result in the exclusion of the unfit. Some, indeed, are of the opinion that licensing would afford cover to the unfit and thereby tend to lower the standing of the profession.

The maintenance of professional standards is regarded as essentially a professional matter, although it is recognized that a strong incentive to excellence is provided by the discernment of employers and clients.

The position of the public in relation to the question of licensing is discussed from the standpoint of employers, as well as investors, in the replies.

Employees are considered to be already protected, or in the way of being protected by legislation applying to those directly responsible. Whether Mine Managers should be regarded as sharing responsibility, and be required to qualify by examination for a license, as in South Africa, is not, as a rule, touched on. It may be observed in this connection, however, that, even in South Africa, licensing does not extend to Consulting Engineers.

Investors are believed to be as well protected as possible and more liable to suffer than to benefit through licensing. Their position is different from that of the general public in relation to the other professions, for their transactions are not of such urgency as to preclude inquiry and verification, the means for which are ample. Licensing would not relieve them of the need for precaution, since, as already stated, it would not eliminate the unfit from the profession, although, it might, in some instances, give rise to a false sense of security and thus obscure that need.

W. L. HONOLD, Chairman
H. G. MOULTON
J. V. LEWIS
A. M. SMOOT
F. F. SHARPLESS.

A METHOD has been successfully tried for rendering aluminum and its alloys proof against rust, according to a writer in 'Industrial Engineering'. An electrolyte is made up of a sulphur compound of molybdenum and zinc employed as the anode, constituting a cell with the aluminum as cathode. By maintaining the cell at a temperature of from 60° to 65° the aluminum becomes covered with a dark brown coating which proves adhesive and rust-proof against the most stringent tests. The metal may be bent or rolled without cracking the coating, and has been immersed by way of test in a salt solution for two months without showing a trace of corrosion.

DISCUSSION

The Magmatic Origin of the Chalcopyrite and Bornite at Engels

The Editor:

Sir—In the article on the Engels mine by Mr. A. B. Parsons, in your issue of July 30, there appears a reference to a paper by H. W. Turner and A. P. Rogers on the ores of that mine, and subsequent articles written by L. C. Graton and R. P. McLaughlin. Mr. Parsons draws the inference that the conclusions of Turner and Rogers are wrong whereas Graton and McLaughlin are correct, referring especially to the formation of copper glance, or chalcocite, which in most copper deposits is undoubtedly a product of downward sulphide enrichment. A discussion of this matter requires the production of a mass of scientific data, which can only be digested by expert petrographers and metallographers. It is not the purpose of this letter to discuss the occurrence of chalcocite at the upper Engels mine, as it is of minor importance, and according to Mr. Parsons, chalcocite ore has given out in the lower levels of the main orebody. Suffice it to say that in most copper deposits where glance is an important constituent of the ore, pyrite is usually present. This mineral readily oxidizes, forming, as one result of the reactions, sulphuric acid, which leaches out the copper and silver of the ore and carries these metals in solution to lower levels, where they are precipitated forming the well-known zones of sulphide enrichment. Chalcopyrite and bornite oxidize less readily, and hence supply less acid. There are three reasons why no such strong zone of sulphide enrichment exists in the upper Engels mine:

(1) The absence of pyrite as noted above and hence the lack of abundant acid to leach out the metals and carry them to lower levels.

(2) The density of the orebearing rock making it difficult for the descending solutions to penetrate it.

(3) The lack of strong shearing or fissuring, so that spaces for downward percolation of waters were largely lacking.

For these reasons, the amount of secondary chalcocite in the Engels deposit is insignificant compared with its occurrence in many other copper deposits. It is probably safe to say that 95% or more of the copper produced at the Engels mine comes from bornite and chalcopyrite. These two minerals form the 'bread and butter' of the mine, and it is therefore of great scientific and economic interest to determine if the chalcopyrite and bornite are of magmatic or hydrothermal origin. If of magmatic origin it is very likely that the deposit may extend to a

considerable depth and if one ore lens gives out it may be replaced below by another lens as in the similar Tweekfontein mine in Africa. If of hydrothermal origin, it is probable that the ores will give out at a comparatively shallow depth, for the reason that there is no strong fissuring or shearing at the Engels deposit such as occurs at all deep sulphide metal mines of hydrothermal origin.

To discuss the origin of the ore, it might be well to define magmatic and hydrothermal deposits, although in nature there may be, and probably is, a gradation from one to the other. Most mining geologists of the present day including, I presume, Messrs. Graton and McLaughlin, ascribe nearly all metalliferous deposits, such as the copper, gold, and silver mines of the Western States, to magmatic waters arising from a magma in depth and depositing their valuable contents in fissures and in adjoining wall-rocks comparatively near the surface. Such deposits, however, would be called hydrothermal, since water is the chief agency in transporting the metals from depth to the veins where we now find them, and frequently (as in the Mother Lode gold belt) the veins are not in the igneous rock from which the metals came, but in older sedimentary or schistose rocks.

Magmatic deposits, on the other hand, may be designated as deposits originating in the magma in which we find them without being transported any great distance through fissures, sheared zones, or porous rocks. All magmas contain water, which in the gaseous form is a mineralizer; and other mineralizers may be present and active, and yet if the ores are deposited at their place of origin or nearly so, the ores being original in the magma, it will be perfectly proper to designate the deposit as one of magmatic origin, even though modified and rearranged by pneumatolytic or hydrothermal agencies, in contradistinction to one of plainly hydrothermal origin in which the metals are brought from remote sources by ascending waters. This definition will probably suit neither Tolman and Rogers nor Graton and McLaughlin, but is here used to emphasize the great difference between a deposit like that of the upper Engels mine where the ore-minerals occur in a fresh massive dioritic rock, and one, say, like the Butte deposits, which clearly occur along fissures extending to great depth.

Moreover, in the last analysis, if the present prevalent theory that nearly all gold-silver-copper deposits containing sulphides owe their origin to waters originating in magmas, all such deposits are in a broad way magmatic; but for practical purposes can readily be separated into two series:

(1) Hydrothermal: those in which the metals have been transported a considerable distance.

(2) Magmatic: those in which the metals and sulphides originally crystallized out in the parent rock at or nearly at the points where we now find them.

At one extreme we have the Butte copper veins, the gold veins of the Mother Lode, the silver veins of Tonopah, etc.; and at the other extreme, deposits like that of the Engels mine, the famous Sudbury pyrrhotite-nickel deposits, and the copper deposits of Namaqualand in South-West Africa.

The only expert petrographers and metallographers that have studied the Engels deposit, so far as I know, are Tolman and Rogers of Stanford University and Graton and McLaughlin. The original paper by Turner and Rogers has already been referred to. But at a later date Professors Tolman and Rogers obtained suites of specimens of ores from many other magmatic deposits and spent a year or more in carefully investigating them. This research work was published in a bulletin of Stanford University in 1916 and forms the best general review of the whole subject of magmatic deposits that has appeared in recent years. However, it is not referred to in the paper by Graton and McLaughlin published at a later date in 1917, in 'Economic Geology'.*

If now we take the papers published by the experts above referred to, we may note that they do not greatly differ concerning some of the main features of the origin of the chalcopyrite-bornite orebodies; and this is the only matter of practical importance in the discussion. Both consider that the ore was deposited after the silicates. Tolman and Rogers consider this to have occurred soon after the crystallization of the silicates, chiefly by the action of mineralizers (pneumatolytic) with some later hydrothermal action. Graton and McLaughlin divide the various processes, resulting in the formation of the ore, into four divisions, but state that these "four stages covering the time from initial magmatic conditions to the close of the primary mineralization, are merely convenient divisions of an uninterrupted sequence", and further state that "the orebody is in our opinion a direct result of igneous action; but was formed as a final concentration following the crystallization of the rock and not as a magmatic segregation".

If one may criticize the papers by Graton and McLaughlin, it may be said that as a whole they give the impression that the orebearing diorite of the Engels mine is a much altered rock, whereas from a petrographic standpoint it is usually quite fresh. By over-emphasizing what they consider evidences of hydrothermal action, one would draw the conclusion that the deposit is similar to the typical hydrothermal deposits as understood by mining geologists in general. A careful reading of their

conclusions, however, suggests that that is not their meaning, but that it is a direct result of igneous action and not brought up from unknown sources. It may also be said that under the head of Intense Hydrothermal Period they emphasize the formation of chlorite, sericite, and epidote, as evidence of strong hydrothermal action. As a matter of fact these minerals, especially chlorite and sericite, are common throughout the Sierra Nevada granitic rocks, the sericite being derived largely from feldspar and the chlorite from biotite. An absolutely fresh granitic rock is a rarity anywhere in the world, as any competent petrographer will testify. Absolutely fresh granitic rocks are certainly rare in the Sierra Nevada and the sericite, chlorite, and epidote in them are no doubt the product of hydro-metamorphism, which implies hydrothermal action. It in no sense implies such *intense* hydrothermal action as is seen in vein deposits in general. On the contrary, it implies mild hydrothermal action. Otherwise we must regard the great granite batholith of the Sierra Nevada as having been subjected to intense hydrothermal action at many places.

In reference to the Superior deposit, also in a granular igneous rock (a form of grano-diorite), the statement is made that pyrite is absent. This may be true of the ore itself, but it is not true of the grano-diorite country-rock, as may be seen in the original lower Superior tunnel, where pyrite coats the joint-planes.

The stockholders of the Engels mine probably do not care what the origin of their copper ore is, so long as it is of commercial value and continues in depth or laterally; they are interested in the matter to this extent, however, that if the deposit is of magmatic origin, taking my rather wide definition of that term, they may be assured that the present ore lenses may extend to a considerable depth, and that other similar lenses may be found. If, on the other hand, it is of hydrothermal origin, as the term is usually used, the ores must soon give out, as the dense nature of the rock and the lack of shearing or fissuring, militate against a vigorous circulation of ascending waters.

The Tariff on Magnesite and Chrome

The Editor:

Sir—I am reliably informed by letter from Washington that the Fordney tariff bill now pending in the Senate, and which passed the House on July 31, provides a tariff on magnesite of \$10 per ton, and places chrome on the free list. Both of these minerals are extensively used in the manufacture of steel, magnesite and chrome being used practically for the same purpose of making fire-brick for use in melting-furnaces.

If the object of the Fordney bill is to give protection to the miners of magnesite and chrome, and to discourage the importation of these minerals from foreign countries, then this bill, if passed in its present form, will prove a fraud and a failure, for it is very evidently written to protect the interests of the steel manufacturers, who

*In a later paper dealing chiefly with the formation of chalcocite, Graton and McLaughlin refer in a complimentary manner to the excellent bulletin by Tolman and Rogers and modify their views in some details, none of which are of importance as related to the main theme of this article, namely to emphasize the great difference between an ordinary hydrothermal deposit and that of the Engels mine.

desire to import these minerals as cheaply as possible from foreign countries. With chrome on the free list, the steel manufacturers will not need to buy any magnesite, but will use imported chrome exclusively.

I am advised that the collection of private individuals who call themselves the American Mining Congress is against a tariff on chrome. If this is true, they are not supporting the interests of American miners, but are under the control of the steel manufacturers of the United States.

An adequate protection duty on magnesite should be \$15 per ton, and this would not be effective unless a similar duty was placed on chrome, because the two minerals are chiefly used for the same purpose. An adequate protective tariff on both minerals above mentioned would give employment to thousands of miners on the Pacific Coast, where numerous mines producing these minerals are located which cannot now be worked because of the lack of a market.

Every person who favors a protective tariff on these minerals should write letters to Senator Hiram Johnson, Senator Samuel M. Shortridge, and other Pacific Coast Senators at Washington, asking that the tariff bill now before the Senate be amended to give adequate protection to the American producers of these minerals.

Placers in Sinaloa

The Editor:

Sir—Relative to your editorial comment of July 30 on the story published in the San Francisco 'Examiner' concerning "Sinaloa placer deposits so rich as to tax human credulity", may I add to your very pertinent and truthful remarks that the reading of the same 'Examiner' story down here in Mexico, where all this wealth is imagined to exist, has afforded old-timers more genuine opportunity for expression through means of side-splitting guffaws than any story which has appeared for some time.

According to a level-headed mining engineer who has resided in Sinaloa for the past twenty years and who has been keeping his eyes peeled during all that period for just the thing mentioned as so abundant—namely gold, it is true engineers from somewhere have been engaged in spending money and enjoying the native delights for some time in the regions mentioned along the Yaqui, Mayo, Fuerte, and Sinaloa rivers. But if said investigators are so tender-footed or soft-headed as to imagine that the native Mexican has overlooked any easy placer pickings, he has something of a jolt coming around the corner. Nor has the lynx-eyed Americano or other foreign mining engineer been so ruthless as to tread four-pound nuggets under-foot for the past generation or two where anything like exploitation by modern engineering would pay.

I have just returned from spending a brief vacation on the Fuerte river, in Sinaloa, and while I admit that the

doves, quails, and cotton-tail rabbits are considerably thicker than hair on a Mexican poodle, yet my instinct to pan a few colors of the good old yellow metal along the banks of the river were rewarded with many drops of perspiration. Evidently the Aztecs had cleaned up all the coarse gold several centuries ago. Only the finest colors of alluvial gold were obtained in my pan, and the Mexican residents of that part of the world were engaged in every other painstaking occupation other than gold-placering.

Would you be terribly shocked to be informed that the 'Examiner' or other Hearst publications are barred from this section of Mexico and can't be bought locally for love or money. It's strange, but true.

ALBERT E. MAVS.

Guaymas, Mexico, August 15.

[We envy the people of Sonora in so far as they are spared the affliction that weighs so heavily on the people of San Francisco. In regard to the main subject of our correspondent's letter, we may mention that we have received other letters to the same effect. One writer says that he is well acquainted with the placer ground along the Sinaloa river, where the richest claims are supposed to be located. The region has been worked by the natives for a hundred years and still yields them a precarious living by the aid of simple methods of mining, but the gravel is so poor that no white man can compete with them. If Mr. Van der Naillen has evidence of the richness of the ground, we shall be glad to hear from him, for we are ready to believe that the absurd character of the article in the 'Examiner' may be due to the ignorance of the reporter who interviewed him and not to recklessness of statement on his own part. If he had a story of genuine discovery to give to the public in this community, he should have sent it to a reputable paper.—EDITOR.]

Indexing Current Technical Literature

The Editor:

Sir—Your editorial, in the issue of August 6, upon 'Indexing Current Technical Literature', prompts the following suggestion: that the current form of presenting the notices of technical articles in the monthly magazine of the Institute could be changed to good effect and advantage to all members, at but a small cost, upon the following lines:

Why not publish the service for distribution upon a card, so that the information can be filed monthly by recipients, and thus be classified and made more readily available. Specialization in the ranks of our members has become so intensive that what interests the coal-mining engineer does not necessarily interest the metal-mining man, nor does the class of papers which interests either of them meet the needs of the engineer wholly engrossed in petroleum mining.

If the Institute will classify this indexing work on some broad lines, each member can subscribe to the particular sections in which he is interested, and have sent him each month either his own particular index-cards,

or all of them that are published, if he so desires. I am in thorough accord with the idea of providing a monthly service of the character now presented, and now that the service is established it should be expanded to its highest usefulness. None will object to the slight additional expense for the more convenient record of the data in which he may be interested.

San Francisco, August 16.

Revision of the Mining Law

The Editor:

Sir—In your issue of June 18 you printed a full text of the proposed mining law, as revised from the old. You also have an editorial bearing somewhat on the subject, reminding your readers that the main desire of a new law was to eliminate the extra-lateral right. You also gave us a history of the efforts which led to the construction of the present law. The Chicago 'Mining World' had started a campaign for the purpose of arousing the mining public and obtain the views of interested parties, some of which might convey valuable information that might be fused on the new law. Many suggestions were received by the same paper. Some showed a keen practical understanding of the business; others were dreams; some were absurd. We even could find often a flavoring of Government ownership. The reader could easily distinguish the parties who had never been affiliated with the game. They might have read of wild-cats, of rich strikes bringing sudden wealth, but had never read of the struggles. The agitation at the time was for the purpose of finding a solution which would put an end to that everlasting litigation, proving a ruination to the parties interested therein, to the locality, as well as casting an aspersion on the industry.

Of all remedies only one solution appeared practical, to wit: the enlarging of claims and confining the owner or owners to vertical planes of his surface boundaries. This proposed new law disposes of the extra-lateral in a very few words, but elaborates on so many different changes that the reader is led as per intuition to want to know why. Let any one who has had experience with the mining game, not only as a locator but as a prospector, who can handle a single-jack, or a miner who takes a shot at a mining claim while supporting his family, or a small company holding good ground but hard to finance, and others who know something about it; let them, I say, read again and again and digest this new mining law, and they will discover it to be the most odious perfidious graft for the big interests ever presented to the American public, favoring especially the porphyry-copper magnate.

It is not my intention to dissect the various clauses of the so-called new mining law, for I am working hard and though nearing sixty years I have at this date this very year almost completed one hundred feet of underground work, besides having earned by the day some two hundred dollars working for a small company located not very distant from me, but others will take the matter up

and not only dissect such would-be law but vivisect it as it deserves to be. However, let us take Section 5, Article A: "A full claim shall be forty acres square, conforming to the four cardinal points of the compass [very good] but the same can be sub-divided into ten acres square, subject to limitations contained in Article B, same Section. Mineral shall not hereafter be necessary in order to locate and hold a mining claim." But here our porphyry friends are showing their Italian hand. Said claim cannot be held over five years except by the money power. The same article provides further on that an extension of five years can be gotten by paying \$50 an acre per year. At that rate an ordinary claim, such as we have today, would pay \$1000 per year. Does the average man grasp the meaning of that? A noted engineer who took an option on my claims in 1912 told me in this very cabin where I am now writing that bearing porphyry contains from 5,000,000 to 7,500,000 tons of disseminated copper ore. Let us place the profit at one dollar per ton. We readily see that our porphyry friends and magnates are not shouldering much of a burden when paying \$1000 per year for such a privilege, or for time to ascertain by drilling whether the ore is there or not. It let the cat out of the bag in Article C of Section 5 when it says: "If discovery of valuable mineral be made by drilling more than one hundred feet in depth, the claim can be made legal."

The reader can peruse Article E, same Section. Article F is a rigmarole about Alaska, carefully preceding Article G. Article G, same Section, reads: "A mining claim must be patented within seven years". There is no choice as we have today, all consideration is waived—it must be done. It does not take into consideration men of small means, of sickness, of locality, whether or not the work attained so far has exposed enough merit to justify a patent. No. The owner or owners must lose their work, their discovery, for no man would dream, even if he could spare the money, of paying \$50 per acre for forty acres, or most any less money whatever, for a claim which still remains doubtful, for any mining claim carries an element of risk short only of a developed and exposed mine. And we are told that the above said law is evolved by a select few. Where would poor old Tom Cruse have found himself? He couldn't even get flour. All he had in the world was a stout heart, and Providence gave him time. Laughed at, scoffed at, he won out because he had the heart, the spirit, and nature gave him health. There are and have been a great many Tom Cruses, but the select few are too big to understand that.

In Article G the big interests have other innings, for they have twelve years to prove up on their original non-mineral location. A word here for the non-initiated. On a patent the Government gets five dollars per acre. The additional cost right here was three times that much before the War. What would it cost today? I do not know, for I have not inquired, but certainly it is not less. Section 10, cinched by Section 11, imposes excessive hardships to the pocket-book of the prospector and men of small means. The monument of old sub-divisions are

hard to find at times and not always correct, for some were placed a hundred feet out of line. To rectify same, it would cost time and money. We pretend to have so much solicitude for the disappearing prospector, and that law will certainly not bring him back. He is the one who finds the mine or reveals the index leading thereto. The engineer follows and may make the mine, but he never finds it. The engineer field-man is over-cautious, for it pays him to be so, and I for one don't blame him. We find him nice and well-versed but we know by precedent that he is not infallible. As to the geologist, he is certainly useful, but he is not master of the trade. More could be said about this said mining law or about the lot of the prospector; for my part this should suffice.

Juno, Nevada, August 15.

Non-American Issues

The Editor:

Sir—In your issue of June 18, when referring to Rear-Admiral Sims' utterances at London banquets and luncheons, in regard to the Irish question, you state, "It is inadvisable, if not worse, to permit our national solidarity to be disintegrated by a controversy over a non-American question". This bit of advice is similar to that of Washington's advising us against entangling foreign alliances. All of which is sound advice. But what are we to do when a people, citizens and non-citizens, insist on injecting non-American questions into our politics? We don't have to go to Europe to get entangled into European affairs, they can easily be brought over here. They are being brought over here. From what is transpiring it looks as if we might fight 'The War' over at every election, as, in the past, we have fought the Civil War over at every election. A condition might easily prevail here similar to what existed in the Balkans and in Denmark before the War. In the Balkans they had their German party and their Russian party, and in Denmark they had their English party and their German party.

A worse state of affairs can hardly be imagined. It is something to be guarded against. Advising against it helps a little; but it is not sufficient; something else must be done. Something must be done to prevent any non-American faction from controlling elections. The present methods do not do this; they, in fact, make such a thing possible. The whole thing is a question of voting.

The following is a description of a method of voting that, I think, will prevent any particular faction from controlling elections. It is the compromise method of voting. A method of voting whereby competent and impartial officials can be elected in one election, if officials

are elected directly from candidates nominated by petition. The problem in electing impartial officials is how to prevent any party, religious sect, order, race, nation, or any body of men whatever from controlling their election, for if any of these control the election of an official, that official must be partial to them.

The method is as follows: Where one is to be elected, vote for the least majority of the candidates. The least majority is the first number larger than one-half the number of candidates running; for example, if three are running, vote for two; if four are running, vote for three; if five are running, vote for three. By causing the voters to vote for one more than one-half the candidates running, we force them to compromise on some one candidate. Being a compromise, an officer's election by this method of voting would not be due to any particular party's influence. He would, therefore, be able to act impartially.

It would work somewhat as follows: Of a number of candidates running for an office, a voter's first choice would be the candidate who would serve his interests the best, his second choice would be the candidate who would serve his interests next best, and so on. The first choice of another voter, whose interests are opposed to those of the first voter, would be the candidate who would serve his interests best, his second choice would be the candidate who would serve his interests next best, and so on. The candidate chosen last by one side would most likely be the last chosen by the other side, and would, therefore, receive the most votes. The last choice of a voter would be considered less friendly than his first choice, yet more friendly than the first choice of an opponent. There would be no first, second, or third choice marked on the ticket; these terms are simply used to show the working of the method.

The method will help to get competent men in office, because acts of ignorance have much the same effect as acts of partiality. Therefore, the incompetent will be eliminated as well as the partial. Much the same method is used in selecting a jury. The only difference is, in selecting a jury the undesirable jurymen are eliminated, and by this method the desirable are selected. The result is the same. Prize-fighters use practically the same method or principle in selecting their referee. The same principle is used in buying and selling in the open market.

This method of voting may be called the compromise system of voting. Or it may be called a concurring-majority voting system to distinguish it from disagreeing-majority voting systems, as all other systems may be called.

Nothing will stop so effectually the ill effects of any attempt to inject non-American questions into our politics as a method of voting, such as compromise voting, that will give us competent and impartial officials. The question of injecting non-American questions into our political affairs is far more serious than most people imagine. During the War it was reported that Von Kuhlman had told a French ambassador in London, some time before,

that he had worked out a scheme whereby Germany could control the politics of the United States. He said the Germans had not interested themselves in politics like other people, like the Irish for instance. If they had they could easily control the politics of America. There is no use arguing it can't be done because it has never been done in the past. The only reason it hasn't been done is because there has never been any well organized effort made to do it. With all the various propaganda bureaus in this country, we are in a fair way to witness the effect of such an effort.

The compromise system of voting is based on the principle of compromise rule, which is truly democratic, instead of being based on the principle of majority rule, which is, essentially, no more democratic than minority rule or kingly rule. The doctrine that majority rule is democratic is a lie and an illusion. It is the greatest obstacle to right political thinking in the world today. It is the greatest political superstition of all time. And not until we have thrown it into the scrap heap with the divine right of kings will we ever make much progress politically.

WM. CROCKER.

Prescott, Arizona, July 26.

At a recent meeting of the Society of Chemical Industry, in London, Dr. L. Levy and D. W. West, in discussing the industrial respirator, said that it consists essentially of two parts: a face-piece and an absorption apparatus. The face-piece may consist only of a mouth-piece and nose-clip, but this form causes much discomfort and affords no protection to the eyes. The second and more recent form is a complete mask of rubber fabric with eye-pieces of glass so arranged that the incoming air passes over the inner surface of the glass, thus preventing dimming by moisture from the breath. This form requires neither the use of a mouth-piece nor of a nose-clip, and may be worn for a much longer period than the former type. The purifying canister is of the form used in the small military box-form respirators, and the substances employed for absorption should have a high capacity and rate of re-activity for the gases to be removed from the inspired air. The absorbents used vary according to the toxic substance to be dealt with; crystallized copper sulphate, highly activated charcoal, and a mixture of alkali and charcoal powder are used, respectively, for ammonia, hydrocarbon, and other neutral gases, and acid gases. A satisfactory means of removing smoke and solid particles is a mask of fine felt, fitted with an efficient non-return valve for the egress of the expired air. No absorbent for carbon monoxide is known that is suitable for use in a respirator, and, therefore, the catalytic oxidation of this gas by oxides is employed. But this method has certain disadvantages, for example, the harmful effect of moisture upon the catalyst (which may be overcome by a preliminary passage of the gases through calcium chloride), the absorption of a portion of the atmospheric oxygen to oxidize the carbon monoxide, and the absence of any indication of failure in

the respirator. The last-named defect may be remedied by using an upper layer of iodine pentoxide and sulphuric acid which, when any carbon monoxide unoxidized by the catalyst is absorbed, liberates free iodine vapor that acts upon the throat of the wearer and thus indicates the breakdown of the purifying medium that is used.

On the closing days of the last calendar year, December 30 and 31, 1920, the movement of gold between America and the Far East reversed its course, and the current for the first time in over two years began to flow toward the United States, writes Economist Consul F. E. Lee from Shanghai. In 1919 China as a whole imported gold bars and bullion to the value of \$79,295,738, U. S. currency. Fully as much was imported in the first seven or eight months of 1920; but at the end of that period the unsettled market conditions in the United States and the rest of the world virtually wiped out China's export trade, and its capacity to absorb the yellow metal ceased. When at the close of the year and in the days preceding the Chinese New Year, February 8, silver exchange dropped to 2 to 1 and below, two dollars Mexican for one dollar gold, the Chinese dealers began to take their 100% profit on their gold purchases, and export began. From the port of Shanghai alone the exports to the United States between December 30, 1920, and February 21, 1921, amounted to approximately \$10,000,000 gold. The principal cause for this export of gold is that it is an exchange transaction in which the Chinese dealers have made large profits. Much of this gold was purchased when \$1 Mexican would buy \$1.14 gold. A second cause for this export is that with the stoppage of exports and the impossibility of consignees accepting imports because of the unsettled conditions, less gold is required by the foreign-exchange banks in handling foreign-exchange transactions, so the surplus is being sent to points where it is more readily convertible. The revival of export trade will cause a greater demand for silver, and gold is being exported in order to purchase silver with which to make purchases of export stocks in China. The attractive opportunities in American securities at the present time may also have some bearing on this movement of the precious metals.

THE report for the year 1920 with regard to the administration of the territory of Papua states that it has been a successful one, and that the increase in exports and revenue was large, and the returns generally of an encouraging nature, says the weekly bulletin of the Department of Trade and Commerce of Canada. The revenue amounted to nearly £80,000 as compared with £61,000 for the preceding year. The value of imports was £422,741 as compared with £258,112, and exports amounted to £270,481, as against £176,247 for 1919. Osmiridium, which has been found in Papua for some years in small quantities, is recorded for the first time as an export, the amount exported being 88.5 oz. Gold exports also showed a slight increase. Only a small amount of silver is produced in the territory.

REVIEW OF MINING

HAYDEN BILL BECOMES LAW

President Harding has signed the bill introduced by Carl Hayden, Congressman from Arizona, providing for a change in the 'assessment' year with respect to unpatented mining claims. Claim owners will have until 12 o'clock noon, July 1, 1922, in which to complete assessment work for the year 1921. Thereafter the work for each year must be completed by noon of July 1 instead of by midnight of December 31, as formerly. Work for the year 1920 became delinquent at midnight of July 1, 1921, according to the provisions of the former law that made work performed on or before July 1

change or annul absolutely a congressional enactment, but they may in effect modify the application and enforcement of the laws. These decrees may be issued at any time, and it is highly important for concessionaires to keep advised as to the latest decree. The same statement applies to the orders in council issued by the Canadian government. The commissions of many of our own States have wide authority in regulating the operations of State laws, and their regulations are subject to change and amendment. Compliance with any such decrees, orders in council, and rules of the State commissions is as essential as obedience to the

The New Mill of the Simon Silver-Lead Co. in the Simon District, North of Mina, Nevada

applicable as of the calendar year 1920. Work commenced before midnight of July 1, 1921, could be continued uninterrupted until the required amount was performed; that is, no adverse claimant could re-locate the ground while the former claimant was engaged with his work even though the prescribed time had passed.

BULLETIN ON LAWS REGULATING PETROLEUM PRODUCTION IN AMERICA

The publication of Bulletin 206, 'Petroleum Laws of all America', by J. W. Thompson, law examiner, is announced by the United States Bureau of Mines. The bulletin includes the petroleum laws of the United States, the several oil-producing States, Canada, Mexico, and the Republics of Central and South America. The report has been prepared in response to the wide demand for information regarding the laws regulating leases and concessions, and the explorations for and exploiting of petroleum in these Republics. The petroleum laws of the Spanish-American Republics are usually supplemented by decrees of the Presidents, which serve the purpose of regulations. Such decrees may not

laws themselves. Copies of the bulletin may be obtained from the Superintendent of Documents, Washington, D. C., at a price of 40 cents.

SIMON SILVER-LEAD CO. IS COMPLETING ITS MILL

The new 150-ton flotation plant of the Simon Silver-Lead Co., in the Simon district north of Mina, Nevada, is practically complete except for the erection of the flotation machines. The machinery has been shipped from San Francisco and the timber is already framed at the plant so that but one week's work will be required to install the flotation equipment. The ore, as supplied to the mill, will average 5 oz. silver, 8% lead, and 9% zinc; the treatment will be preferential flotation, the lead being removed by the first machine, while the zinc is dropped. The tailing from the lead machine is then to be passed through a second for the flotation of the zinc. Lead concentrate will be shipped to the U. S. smelter at Midvale, Utah, whereas the zinc product will go to a smelting plant at Harbor City, California, that was recently purchased by the Simon interests. The details of the metallurgy there are not fully determined, but lead-silver bullion and lead-free zinc oxide will be the products.

The situation of the plant at tidewater will be an advantage in marketing the oxide.

The power-line being built by Mineral county from Hawthorne to the Simon district is expected to be completed by October 15. The post-holes have been finished and the poles and wires will be on hand soon. The work is under the direction of Joe Beane. Everything at the mine and mill will be in readiness for immediate operation as soon as the electric current is available.

Development work in the mine has been discontinued for the time being and the task of putting the chutes, tracks, bins, and skips in shape for steady production is in hand. A new ore-pocket is being built below the collar of the shaft to provide storage capacity at this point. The ore will be withdrawn in a short adit and will be hauled through it and around the contour of the hill to the mill crushing plant which is about 300 yards away. The ore-reserve totals 500,000 tons of assured ore of the approximate grade mentioned above.

Mr. P. A. Simon, president and general manager for the company, is well satisfied with the mill, and while he doesn't, as he says, "expect to press the button and have everything start without a hitch", he is confident that regular shipments of concentrate will start well before the first of the coming year.

FINANCES OF UTAH COPPER COMPANY

The interesting feature of the report of the Utah Copper Co. for the second quarter of this year was the item of \$547,584 for 'shut-down expenses' of its mine and plant. While at first glance this seems to mean that the big copper company is spending at the rate of \$2,300,000 per year to stay closed down, such is not strictly the case, says the 'Boston News Bureau'.

In the quarter just reported, Utah had to clean up raw copper in process and finish up other work in hand; the last few pounds of mine production on hand at the date of the shut-down, April 1, was put through the reduction works. This resulted in an output of 1,406,000 lb. of copper, but the expense of keeping the plant in operation to treat this amount was almost as heavy as though the usual monthly production was put through. It is doubtful, however, if monthly expenditures hereafter will exceed \$100,000. Utah Copper in the second quarter again dipped into surplus to continue dividends, the tenth consecutive quarter it has done so. Including the deficit of \$1,254,474 after dividends shown in the second quarter, Utah thus far this year has disbursed nearly \$3,000,000 from its treasury. In 1920 its deficit after dividends amounted to \$4,317,207 and in the year before that, \$1,494,544. In the last two and a half years, therefore, Utah has paid out in unearned dividends over \$8,782,000.

Its ability to do this is a direct reflection of the conservative action of the management during the prosperous war days. In the four years ending in 1918, Utah Copper earned \$65.61 per share on its 1,624,490 shares of stock, after all reserves for depreciation, depletion, and extraordinary taxes. Of this it distributed \$40.75 per share in dividends, leaving nearly \$25 per share turned back into the treasury, as per the following:

	Net earnings per share	Surplus after dividends
1918	\$11.66	\$2,700,880
1917	18.46	6,430,002
1916	24.46	19,655,064
1915	11.03	10,462,665
Total	\$65.61	\$39,248,611

This resulted in increasing the earned surplus from \$13,552,000 at the end of 1914 to nearly \$51,000,000 at the end of 1918.

W. P. HAMMON OPTIMISTIC REGARDING GOLD MINING

W. P. Hammon, who is prominently identified with the gold-dredging industry, recently returned to San Francisco from a four months business visit in the East and in the Mountain States. He is optimistic regarding business in general; apropos of gold mining, he is quoted as saying:

'There is no question that capital has resumed its interest in the gold-mining industry. It is revivlag in Colorado and throughout the entire mountain region. I was able during my trip to finance a \$1,000,000 transaction, and that is a good indication, because six months ago it would have been impossible to interest capital in such an undertaking. In the mining towns, the workmen are clamoring for something to do, and the State officials are ready to help all they can. I was considering a big hauling contract in Idaho, to move machinery to a mine. Of his own accord, the supervisor of roads in that district called on me at the hotel, and next day put a large force of men repairing the road, so as to save us money on our haul. In fact, I am enthusiastic over the excellent spirit displayed by everybody in reviving the gold-mining industry.'

FRESNILLO STARTS PRODUCTION

According to the 'Financial Times' (London), the Mexican Corporation announces that the first unit of the Fresnillo mill consisting of one-half of the plant has commenced operations. It is anticipated that the remainder of the plant will be brought into operation in September. The Fresnillo silver mine, in which the Mexican Corporation will have a large interest, is situated in the State of Zacatecas. The Fresnillo consists of two ventures—one of the immense quantity of ore comprised in the Cerro de Proano, and the other the old mine worked many years ago below the surface deposit just referred to. The Cerro de Proano is a small hill about 300 ft. high which rises out of the surrounding plain. It has a circumference of about two miles, and consists almost entirely of a mass of silver-bearing veins running in all directions. After an exhaustive examination, the profitable portions of this mass of ore were estimated to contain a minimum of 4,000,000 tons, with an average value of about 5½ oz. silver. Since the taking over of the property more extensive development and exploration work has been carried out, with the result that it is now estimated that a further 2,000,000 tons of ore can be regarded as ultimately available. Very little labor is required in working this body of ore. Adjoining this hill is the old mine, which has a long history, and which, from reliable records, had produced, up to 1903, over 150,000,000 oz. of silver.

FUTURE OF GOLD INDUSTRY

F. H. Hamilton, speaking as chairman at a recent meeting of the H. E. Proprietary company, in London, said:

"I should be the last person to venture any dogmatic opinion upon a question the factors of which are so complex and confused. I may, perhaps, be permitted to state, however, that I believe the time when the gold industry will come into its own again is not at all remote. A distinct change of sentiment is already apparent. It is, I think, today generally recognized that a policy of artificial deflation which does not correspond with or represent an increase of commodities is just as disastrous as the contrary policy of sudden inflation by the wholesale manufacture of credit. Each of these policies has been tried; the gold-mining industry has suffered from both. When the pound declined in value the cost of all material was higher, and labor on the Rand seized the opportunity to raise wages. When, again, our own Treasury attempted to deflate currency and to raise the relative value of the pound the premium on gold declined, but wages remained at the old

level. The consequence is that the gold industry was bled at both ends. It retaliated in the only way open to it by falling into a decline, not because it was sulky, but because, whatever advanced politicians may say to the contrary, an industry cannot pay more out than it has in it.

"One result is that the production of gold all over the world fell from about £93,000,000 in 1914 to £73,000,000 in 1919, a reduction of over 20%. Another is that many of the low-grade mines on the Rand have been living from hand to mouth, and white labor has been faced with this dilemma: that unless a reduction corresponding to some extent to the decreased prices of commodities is made many mines will be forced to close down and a large amount of unemployment will ensue, which will ultimately force down wages. It would almost seem today that the tide has turned. There

finally, that if it could succeed the political consequences would be of a disastrous character. If this view is correct it follows that gold mining has already passed its worst period, and that we are likely within the near future to see a much larger margin of profit on the medium-grade mines."

PORTLAND CANAL MINING CONGRESS

The Portland Canal Mining Congress has recently been organized as the first step in a concerted effort to bring more generally to the attention of the mining public the mineral resources of the region centring at Hyder. The remarkably rich Premier mine, lying almost on the boundary between Alaska and British Columbia, is the mainstay of the district at the present time, but shipments have been

Members of the Portland Canal Mining Congress

From left to right, rear: F. C. Lawrence, Dan Lindeberg, Angus Kennedy, J. A. Hall, William Forrest, Bernard M. Stone, Dr. W. D'Arcy Chace, R. J. McDonnell, Oren F. Hill, D. W. McLeman, S. G. Benson, John T. Reed, U. S. Commissioner, M. R. Jamieson, W. J. Crawford, E. R. Stivers, Customs Officer, James Nesbitt, William Bunting, P. C. Beaudreau, Charles Traversy, Captain John Irving, S. P. Fitzgerald, John Hovland. Front row: Dale L. Pitt, W. R. Tonkin, Dan Davis, Hugh MacDougall, M. Meisingseth, N. Beyin, W. R. Hull, James Daly.

are signs of a disposition on the part of white labor to meet the situation by reasonable concessions, and a certain measure of relief in this direction may be hoped for which, of course, would be reflected in working costs. The price of mining material has already declined.

"Then there is the question of the gold premium, and here, too, the industry seems likely to benefit. The idea seems at one time to have gained currency that this gold as measured by the pound sterling is a temporary phenomenon and that before long it will disappear; and that it will be possible for the country to return permanently to an effective gold standard. It would be out of place at this meeting to discuss the strong and, I think, convincing reasons that exist to the contrary. I will merely content myself by stating my own confident belief that for the next ten years, and probably for a much longer period, the pound sterling will be at a discount relatively to gold; that any attempt within that period which this country may make artificially to deflate to the gold level must fail, and,

made from a number of other properties and the future prospects are bright. Plans have been made for sending an exhibit to the exposition to be held at Chicago in October under the auspices of the American Mining Congress. The accompanying illustration shows the group of mining and business men who organized the Portland Canal Congress. John T. Reed was selected as permanent chairman and Bernard M. Stone as secretary.

DELAY IN ALLOWING REDUCED FREIGHT-RATES TO BECOME OPERATIVE

The Interstate Commerce Commission has temporarily suspended the proposed schedules that would reduce sundry rates, including many applying to shipments of ore and bullion. The delay in most cases is for three months and for the purpose of allowing additional investigations to be made by the Commission. With the railroads ready to make the reductions in many instances, it hardly appears logical that the Commission should not allow the rate-

reducing schedules to take effect immediately. Explanation is offered that two factors govern the Commission in its allowance of rate reductions. It must balance cuts in rates so that one road will not gain an undue advantage over another and it must also watch the interests of industries in order to prevent any unfairness of competition to enter through inequality of rates. Another reason that makes it necessary for the Commission to consider these reductions with care is that it must be determined that the returns will not fall below the guarantee given the roads.

WAR MINERALS RELIEF TEST CASE PENDING

It is reported that Charles Dawes, Director of the Budget, will seek to have returned to the Treasury the unexpended balance of the 'war minerals relief' appropriation amounting to over \$5,000,000, but that this action will be opposed by the Interior Department, on the ground that the money should remain available until all claims are settled. Many of these are held up pending action by the House on the bill already passed by the Senate providing for more liberal interpretation of the Act. The necessity for this legislation is apparent from the decision of the Comptroller General declining to re-open the case of Samuel H. Dolbear for an additional allowance of \$2840. This was considered a test case, as, had the Department been able to re-open it, it could make additional awards in other cases. The Comptroller holds that government accounting officers are not authorized to re-open, on questions of law merely, accounts which have been settled by their predecessors. He also was disinclined to exercise any jurisdiction in this matter while measures for the claimant's relief are pending before Congress.

RICH ORE SHIPPED FROM KENO HILL IN THE YUKON

Silver and lead ore valued at \$600,000 from Keno Hill, the new district on the Stewart river, near Mayo, Yukon territory, reached Seattle recently. It was forwarded to the Selby smelter, near San Francisco. There are 3000 tons of ore in the consignment, valued at about \$200 per ton. The ore was sacked at the mine before shipment by the Yukon route to St. Michael.

ARIZONA

Bisbee.—The Copper Queen branch of the Phelps Dodge Corporation has had a force of electricians at work recently installing a Gamewell fire-alarm system through the various buildings that belong to the company. There has been ordered a La France fire-truck similar to that owned by the city. The central station of the company will be at the Lowell shaft, where the truck will be housed. Three shifts of men will be on hand to respond in case an alarm is turned in. The Copper Queen hotel, the Y. M. C. A. and Y. W. C. A., the Western Union building, the dispensary, the store and warehouse, and other buildings belonging to the company are being connected with the system. In each building there will be a number of boxes from which the alarms can be turned in. In a number of the buildings there will be master boxes which will show where the fire is located when an alarm is turned in. The system will also be connected with the central fire-station of the city at the city hall and also at the Lowell fire-station, so that the alarm will register there.

The second quarterly report of the Shattuck-Arizona Copper Co. states that 3265 ft. of development work was performed. Regarding the new discovery on the 600-ft. level the report has this to say:

"A new and important discovery of copper ore was made and is now being developed on the 600-ft. level near the boundary of the Roy and Leo mining claims in the north-east end of the property. The ground under development is practically new territory, and as there is a rich copper show-

ing surrounded by a large body of copper-bearing gossan, we are assured of a good tonnage of commercial copper ore in this section of the mine. Ore indicated during the first quarter of the year in No. 86 cross-cut was found in No. 89 cross-cut, and to date we have opened up an ore-shoot for a length of 85 ft. The average content of No. 89 cross-cut is more than 20 % copper and 20 oz. of silver per ton. The new ore is a mixture of copper carbonates and copper sulphide (glance) in an iron gangue. The glance ores assay slightly more than one ounce in silver for each per cent of copper content."

Hayden.—No shipments of direct smelting ore were made by the Ray Consolidated Copper Co. during the second quarter of 1921, and the production from concentrating ore was 1,546,535 lb., as compared with 8,802,186 lb. during the preceding quarter. The operating loss was \$85,619, and plant shut-down expense was \$289,994, making a total of \$375,613. Miscellaneous income was \$5404, leaving a net loss for the quarter of \$370,209.

Kingman.—Reports from the Katherine mine state that 30 men will be added to the force working on development. In addition to opening the orebodies already discovered, a force will start sinking the winze to the 700-ft. level. The tonnage of blocked ore is said to be sufficient to warrant the erection of a mill.

CALIFORNIA

Angels Camp.—W. O. Crosby and W. J. England, who recently acquired the Washington mine, are adding new machinery and remodeling the 5-stamp mill. The deepest workings do not extend below 180 ft.; \$400,000 is said to have been produced from above this point. The new name will be the Bullion Hill Mining Co.

Death Valley.—The Pacific Coast Borax Co. is shipping 20 carloads of borax monthly and the accumulation is being cleared rapidly. Mining will probably be resumed about October 1.

French Gulch.—Work has been resumed at the Gladstone mine after a shut-down of six years. The mine was discovered in 1890, since which time it has produced more than \$3,000,000 in gold.

Quincy.—Rich gold-silver ore has been uncovered in the Plumas-Eureka Annex near Johnsville, according to Dean Durham, president. An adit is being driven to develop the veins.

Randsburg.—The California Rand Silver, Inc., is hastening work on its new assay office. The old office was destroyed by fire on August 19, and the new plant will necessarily be equipped with entirely new apparatus.—A shaft on the Grady's Venture claim has reached the 25-ft. point. A carload of lumber and machinery has been received, and a plant sufficient to sink to 500 ft. will be erected at once.—Thirty stamps are dropping at the Yellow Aster mill. The ore is coming from lessees in the upper levels.

Shawmut.—It is announced that the Belmont Shawmut Mining Co., a subsidiary of the Tonopah Belmont Development Co., will resume output early in September. Production was discontinued in August 1920, when the cost of labor and supplies became prohibitive. The mine is comprehensively developed and is equipped with a 500-ton reduction plant. Recent work has been directed to improving the conditions underground for economical operation.

Sutter Creek.—Preparations are being made for sinking the Central Eureka shaft to the depth of 4100 ft. The shaft is inclined at about 60°.—Superintendents of mines on the Mother Lode held their regular monthly meeting at the Fremont mine on August 27. Edwin Higgins, manager, and B. I. Hoxsle, superintendent, of the Fremont mine, were hosts.

COLORADO

Aspen.—The Silver Mines Company of America, organized and financed in Philadelphia, is treating ores mined in the Cowenhoven tunnel at the Hunter mill; it is also handling custom ores. It is estimated by the company's engineers that there is low-grade ore available to keep the mill in operation for many years and custom treatment will be abandoned when this ore is blocked-out for milling.—The Park Tunnel Co. has under consideration the construction of a tramway and one-half of the necessary \$22,000 has been subscribed by stockholders at Leadville and this city. The tram would take care of ore from both the Park and Jenny Lind tunnels.

Cripple Creek.—Sinking has been resumed at the No. 2 or main shaft of the Portland Gold Mining Co. on Battle mountain. For safety, a winze was sunk outside the station at the 2450-ft. or bottom level, and at a depth of 15 ft. a cross-cut was carried directly under the shaft, providing 15 ft. of solid rock as a bulkhead. The company's engineer had recommended this plan, as a bulkhead could not have been constructed of sufficient strength to withstand the weight of cable and skips in case of accident. The shaft is reported to be comparatively dry, as veins carrying water have dipped out of the shaft. The depth of the present lift will be 200 ft. and the station will be cut at an elevation of 7594 ft., a total depth from the surface at this point of 2650 feet.

Rich discoveries have recently been made at the American Eagles, at the El Paso Gold King, originally located by Robert Womack as the Chance, and at the Lexington on Gold Hill. The last two are surface discoveries.

Leadville.—Four shafts are in operation on the Little Johnnie, where about 150 miners are employed by lessees. A good grade of ore is going out from shafts No. 2 and 4. —The Third Venture Mining Co. is extending the St. Louis tunnel to prospect the Colorado Prince and other holdings on Brece mountain. The Colorado Prince is reputed to be the first mine to find gold in the Leadville district.

Lessees on the Fanny Rawlins are mining and shipping ore broken between the second and fourth levels and shipping steadily to the Arkansas Valley smelter.—The Fidelity G. M. Co., operating in Black Cloud gulch west of Twin Lakes, is mining and shipping smelting ore only, and saving mill-ore in anticipation of constructing a mill. Returns on smelting ore range from \$87 to \$350 per ton.—Work in the Canterbury Hill tunnel project continues.

IDAHO

Coeur d'Alene.—A 10-cent dividend was declared by the Hecla Mining Co., at the meeting in which the company ratified the action of the directors in settling with the Marsh Mines Co. and the Federal Mining Co. The dividend of 10c. per share amounts to \$100,000, and is the third dividend this year, making a total to date this year of \$330,000, and a grand total of \$8,835,000.

Fifty tons of ore has been shipped by the lessees in the No. 4 tunnel of the Western Union Mining Co. This is the nineteenth car shipped by them this year and is said to contain about the best ore they have ever taken out. It was sent to the Bunker Hill smelter at Kellogg.

Fairfield.—The Walton Mines Co., operating 15 miles north of here, expects to finish its mill and commence the shipment of concentrate to Salt Lake City about September 20. Three hundred tons of mill ore, assaying \$20 to \$30, already has been stoped for milling.

MICHIGAN

Calumet.—As a result of further curtailment, 300 additional men have been laid off by Calumet & Hecla. Costs not absolutely essential to the maintenance of the property

have been eliminated in every department. The power-plant at Lake Linden will continue to operate to supply the electric pumps at the mine, while steam will be maintained at the mine to operate the steam pumps and ballers. Sixty-five men have been retained for work on the pumps.

The property of the Superior Copper Co., a subsidiary of Calumet & Hecla, closed since December 1, 1920, has been permanently abandoned. The ground has been thoroughly explored by means of diamond-drill holes, cross-cuts, and drifts, but has been found to be badly faulted. Figuring only mining costs and mine taxes it cost Superior 37.60c. per pound for the 322,871 lb. of copper produced in 1920. The company finished 1920 with a balance of current assets of \$400,650, equivalent to a little better than \$4 per share.

The surface plant of the White Pine Extension Co., owned by the Resource Development Co. of Detroit, is being dismantled preparatory to shipping it to Michigamme in Marquette county, to be set up as a temporary plant at the Imperial iron mine, owned by Henry Ford and recently reopened after a long period of idleness. The Imperial mine is part of the property of the Michigan Iron, Land & Lumber Co., a Ford subsidiary. The removal of the surface plant probably seals the destiny of the White Pine Extension. The mine was under development by the Stanton interests, in association with a number of Detroit men. The results have been only of mediocre character. The problem at White Pine Extension is one involving extensive development and the use of the flotation system for the extraction of the copper.

Calumet & Hecla has added to its already large supply of Danish flint pebbles for its grinding mills at Lake Linden. A cargo of 2200 tons recently was received from Copenhagen. The pebbles are harder than any which can be obtained in this country, and for the grinding of conglomerate 'rock' are more satisfactory than steel. Steel pebbles are used to advantage on amygdaloid 'rock' only.

NEVADA

Divide.—The Tonopah Divide and Divide Extension companies are shipping regularly to mills in Tonopah. The Gold Zone is working at 900 ft. Several of the smaller companies are expected to resume, including the Alto, Junior, and Giant. The Tonopah Divide soon will resume sinking the shaft from the present depth of 1000 feet.

Gerlach.—The Leadville Mines Co. is shipping monthly four carloads of concentrate worth \$150 per ton, or a gross monthly production valued at \$30,000 from the treatment of 30 to 35 tons of ore daily.

Goldfield.—Umpire assays on the 60-ton shipment made nearly a month ago from the Donald and Giles lease on the Florence give the ore a value of \$148.40 per ton. Ore of a gross value of more than \$10,000 has now been shipped by the lessees as a result of their work in the hanging wall of the old Reilly flat stope. Three raises are being driven to prospect the orebody. The lease has been renewed for two years.—Barker, Heiden, and Witt, in the vicinity of the Engineers' stope, are hoisting a carload of \$100 ore, according to their estimate. These lessees have not been in ore for many months and the shipment will consist of ore mined nearly a year ago.

Pioneer.—The Mayflower has levied assessment No. 7, at the rate of 1c. per share, delinquent October 10, 1921. The \$10,000 indebtedness of the company has been reduced by \$2700 during the period from January 1 to August 31, 1920. The report says of the Starlight workings, the most promising in the mine: "The ore exposed at this point outcrops on the surface and assays from \$3 to \$29.60 per ton, the average value being about \$12 per ton, the vein having a width of more than 5 feet.

Ruth.—The Nevada Consolidated Copper Co. is develop-

ing the high-grade direct-smelting ore opened some months ago on the 700-ft. level of the Ruth mine, with favorable results. The operating loss during the period was \$22,605, plant shut-down expense was \$247,090, and miscellaneous income showed a deficit of \$9163, making a total loss of \$278,558. The company has disposed of all metal produced during the first quarter of the year, besides an appreciable amount of the surplus that had accumulated to January 1. The smelter was shut-down late in May.

Tonopah.—The Belmont is setting new records. What is said to have been the most valuable bullion shipment in the history of the company was made a few days ago. This consisted of 60 bars containing \$100,000 worth of silver and \$25,000 worth of gold, saved during the first 15 days of August. A new hoisting record of 201 skips in six hours and 40 minutes also has been made, replacing the old record of 187 skips.—The second shipment this month of the MacNamara mill consisted of 12 bars weighing 20,407 oz. and valued at \$26,000.—High-grade ore from the Divide Extension is being treated in the MacNamara. The Tonopah Extension has sued the Cash Boy for \$15,394 for ore alleged to have been mined by the latter from the Golden Anchor claim of the former. This ore is said to have been taken from between the 1425 and 1470-ft. levels in the period September 1917-July 1921.

UTAH

Alta.—A. H. Cowie has filed application with the State Engineer for the appropriation of 20 second feet of water from Little Cottonwood creek. It is proposed to divert the water at a point 110 ft. below the portal of the Wasatch Mines Co.'s adit; it will be carried through a diverting channel 13,700 ft. long to the point where it is proposed to build a power-house, with a capacity of 1500 hp. to serve mines in this district.

Beryl.—For seven years some development has been in progress at the Copper Zone mine, 12 miles from this station, in Iron county. Recently discoveries of an important nature have been made on the 200-ft. level, and as a result, the management is planning to equip the property with electrically-driven machinery. J. R. Rickards, superintendent, reports that the mineralization is similar to that of the famous Horn Silver mine at Frisco, Utah. Specimens have been found that assay as high as 5000 oz. in silver. The recent discovery, however, shows cerargyrite, native silver, and gray copper. The company has expended during the past seven years about \$84,000 in developing the property.

Eureka.—During the week ending August 20, the Tintic Standard shipped 40 cars of ore; Chief Consolidated, 36; Dragon, 12; Victoria, 12; Eagle & Blue Bell, 11; Iron King, 9; Swansea, 7; Iron Blossom, 7; Colorado, 5; Centennial-Eureka, 5; Mammoth, 4; Bullion-Bee, 3; Gold Chain, 1; Bowers, 1; Tintic Mill (copper bullion), 1; making a total of 154 cars, as against 178 for the preceding week.

Gold Hill.—The Western Utah Copper Co., on its 700-ft. level, has entered a body of silver-copper ore that assays from 6 to 30 oz. in silver and from 4 to 15% copper. The ore has been drifted on for 40 ft., and a raise has been put up for an equal distance. Samples show most of the copper to be in the form of chalcocite and chalcophyllite, in a soluble lime gangue. The main ore-shoot heretofore developed at the Western Utah Copper is 300 ft. long and from 10 to 80 ft. wide. This shoot produced an excellent silver-lead arsenical fluxing ore, and at times as high as 300 tons per day was shipped to the Murray smelter of the A. S. & R. Co.

Grantsville.—Good silver-lead ore has been found at the property of the 'L' Marie Mining Co. by lessees, according to John V. Long, Jr., president. The property of this company is in the Stansbury mountains, about 9 miles from here. The new strike is but 30 ft. from the portal of the adit and 18 ft. below the surface.

Milford.—A large body of silicious ore has been developed in the property of the Leonora Mining & Milling Co., according to John Matson, president. As soon as the company can negotiate a favorable smelting contract, shipments will be started. Two carloads on the dump show returns of 20 to 35 oz. silver. A new shaft is being sunk, and is now at a depth of 145 ft. It is reported that E. J. Radatz, president of the Tintic Standard Mining Co., and associates, have recently acquired a block of stock in the Leonora company.

Park City.—Ore shipments from this district for the week ending August 20 totaled 1212 tons, of which the Judge allied companies shipped 460; Ontario, 395; and Silver King Coalition, 357. Shipments the previous week totaled 1485 tons.

Salt Lake City.—Plans are being made for a convention of metal-mine managers and superintendents of Utah to be held in this city during the first week of October. At this convention practical problems of the industry will be considered, with papers and discussions on appropriate subjects. Arrangements for the meetings are in charge of the following mine superintendents: A. S. Winther, Utah Consolidated mine, Bingham, chairman; William Owens, Eagle & Blue Bell mine, Eureka, vice-chairman; N. A. Dunyon, Ontario silver mine, Park City; O. R. Friendly, Judge properties, Park City; J. D. Shilling, Utah Copper mine, Bingham; and A. G. Mackenzie, secretary of the Utah Chapter of the American Mining Congress.

The largest exposition of the resources and opportunities of the metal-mining industry of Utah ever exhibited will be shown at the State Fair during October, according to plans being made by the directors of the Fair Association and the Utah Chapter of the American Mining Congress. A committee composed of Forrest Mathez, of the Silver King Coalition Mines Co.; E. A. Hamilton, of the United States Smelting Co.; T. P. Billings, of the Bingham Mines Co.; E. F. Birch, of the Knight Interests; and A. J. May, of the Tintic Standard Mining Co. will be in charge of the exhibit.

The Utah Salduro Co., which is the largest producer of potash in the United States, has been taken over by the Allied Chemical & Dye Co. of New York. The holdings of the Utah company are in the western part of the State, on the Great Salt Lake desert. The company has expended about \$2,000,000 in a plant, which has a daily output of more than 100 cars of potash. Last year an average of 200 men was employed.

MANITOBA

The Pas.—Referring to the recent acquisition of the Flin-Flon copper property, the president of the Mining Corporation of Canada is quoted as saying: "Many difficulties and problems will be encountered in the development of this orebody, but the reserves already proved are so stupendous and, there being no metallurgical difficulties, we are encouraged to hope that we have reached our goal in providing for an indefinite life for the Mining Corporation of Canada."

MEXICO

Chihuahua.—Manuel Radrigues, of Uruachi, has located some new claims embracing veins carrying gold, silver, and lead near the old Providencia mine in the Rayon district. The property is to be patented under the name of Mireya.—The Ampliacion Amalla No. 5, situated on the Talamantes hacienda, in the municipality of Jimenez, has been filed upon by Abraham Fernandez, who recently discovered a large body of manganese ore containing silver. He has surveyed a group of 14 claims.—Jose Partida, of the city of Chihuahua, has taken over the Santa Eduwigs mine near Villa Coronado in company with Juan D. Lozoya.

Durango.—A general meeting of the stockholders of the Soto Mines Co., is to be held in New York City on September

20 at the offices of Charles F. Ayer. Plans for the future operations at the mines will be discussed.

Jose A. Vtado has applied recently for titles to El Indio, a group of three silver claims in the municipality of Santiago Papasquilaro.—Andrews & Harrison, representing San Antonio, Texas, capitalists, who are operating the San Mateo mines in the Velardena district, have started using new power-drills. They were formerly producing about 50 tons of shipping ore per week; with the new equipment they expect to double this amount and will increase their shipments to the Chihuahua smelter accordingly.—The Ampliacion del Pichaco mine is being developed by Cruz Herrera. This property is located in the Topia district near several producing mines.

E. Kreklau, operating the U. S. mine in the Velardena district, has entered a body of rich silver ore at a depth of 100 ft. in the main shaft. Shipments are now being made.

Mocorito.—The El Palmerito silver mines have been taken over by Philadelphia interests. Miles Milward, who has been manager for ten years, has been transferred to Idaho by the new owners, and John Cadogan, superintendent under Milward for eight years, is now manager. The company owning the El Palmerito mines, the largest on the west coast, is building a 250-ton mill to replace the old 150-ton plant. The mines have been worked for 20 years.

Zacatecas.—Regulo Fuentes, representing Mario M. Blazquez, has taken up 20 silver-lead claims in the vicinity of Mazapil. The group is to be titled under the name of Ampliacion de San Francisco del Alto.—Flavio Hernandez has taken up some new copper prospects in the Mazapil; he has made application for titles to several claims known as La Abundancia group.—Manuel V. Armida has located six pertenencias embracing a strong vein of rich silver-lead ore in the Chalchihuites district.

ONTARIO

Beaver House Lake.—Work is being centred at the 350-ft. level and a large amount of ore is being blocked out. A large known vein has been entered at that depth.

Kirkland Lake.—Harry Oakes, president of the Lake Shore company, states officially that the physical condition of the mine is better than ever before and that the capacity of the mill has been increased until it is now able to handle close to 70 tons of ore daily.

Porcupine.—A considerable cut in the wages of gold miners is stated to be under consideration by the mine managers. Wages have been reduced in the pulp and paper trades and the silver-mining camps, but remain high at the gold mines, skilled men receiving \$5.25 per day, as compared with \$2.50 before the War. Common laborers get 56c. per hour, the rate paid at the silver mines being 45c. The effect of high labor cost is to prevent the milling of large quantities of 'ore' carrying from \$3 to \$5 per ton in gold, which cannot be economically treated under present conditions. With moderate labor costs this low-grade can be mixed with the high-grade and in this way utilized, thereby enlarging the output and employing more men. The general expectation is that a cut will be made in October.

The Dome Mines has sent out information to American stockholders pointing out that the Canadian government taxes only 50% of the amount of dividends paid by gold and silver mines, allowing the remaining 50% to be considered as capital return. Stockholders resident in the United States are advised to draw this matter to the attention of the authorities with a view to obtaining a similar ruling.

At the Beaumont lateral work is being carried on at the 150-ft. and 300-ft. levels to cross-cut orebodies indicated by diamond-drilling.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

J. H. Curle is in the Congo.

F. W. Bradley is at Juneau.

Arthur W. Jenks is in New York.

P. B. McDonald writes from Leipzig, Germany.

T. J. Jones is on his way from London to Moscow.

William McNeill has returned from Mexico to London.

Waldemar Lindgren has returned to Boston from Bolivia.

Arthur Moffat, of Bendigo, Victoria, was in the Rand recently.

W. W. Meln is at Lake Tahoe; he was in San Francisco this week.

Walter E. Gaby, of Pachuca, Mexico, has been at Tezcutlan, in Puebla.

John D. Hoffmann left San Francisco last week on his way to Siberia.

G. C. Jones, manager of the El Tajo mine, in Sinaloa, is here on a holiday.

John Crawford, State Inspector of Coal Mines for Utah, is in southern California.

G. Cleveland Taylor, of Redding, has been doing professional work at Randsburg, California.

L. Maurice Cockerel was at Los Angeles this week, on his way from London to Zacatecas, Mexico.

Arthur L. Walker, Professor of Metallurgy in Columbia University, has been on a tour in Europe.

E. P. Mathewson sails from New York for Burma, by way of London and Marseilles, on September 22.

Spencer C. Browne Jr. was married to Miss Lina Ferguson at Albuquerque, New Mexico, on August 10.

George Otis Smith, Director of the U. S. Geological Survey, has returned to Washington from London.

H. S. Munroe, general manager for the Granby Consolidated, has returned from New York to Vancouver.

R. E. Griggs, formerly at Johannesburg and now a resident of New York, was in San Francisco last week.

T. Skeves Saunders has resigned as manager of the Dos Estrellas and has opened an office as consulting engineer in Mexico City.

John A. Agnew and A. Chester Beatty are included in the committee of seven selected to advise the board of directors of the Burma Corporation.

M. V. Harper Carter, formerly of Platteville, Wisconsin, has been appointed Chief Engineer to the Harbor Department of Oakland, California.

Frederick Lyon, former vice-president of the U. S. Smelting Co., spent several days in Utah recently. He is on his way to California for an extended stay.

H. L. Smyth, Professor of Mining at Harvard, has been spending the summer in Michigan, as consulting engineer to the Cleveland-Cliffs Iron Co., of Ishpeming.

John D. Ryan, chairman of the Board of the Anaconda Copper Mining Co., who has been spending the summer at Swan Lake, Montana, has returned to New York.

I. N. Goff, of Pittsburgh, Pennsylvania, general manager for the Keystone Metals Mining Co., is making an examination of the company's holdings near Castleton, Utah.

Jesse J. MacDonald, representing James Irving & Co., of Los Angeles, has returned from the Bradshaw mountains, Arizona, where he made an examination of the Crown King, Wild Flower, and Tiger mines.

Paul Armitage, a director of the United Verde Extension Mining Co., visited the company's property in Arizona recently. He is now in the Yellowstone Park, and will return to New York early in September.

THE METAL MARKET

METAL PRICES

San Francisco, August 30

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	6
Copper, electrolytic, cents per pound.....	12.25—12.50
Lead, pig, cents per pound.....	4.05—5.05
Platinum, pure, per ounce.....	\$78
Platinum, 10% iridium, per ounce.....	\$96
Quicksilver, per flask of 75 lb.....	\$47.50
Spelter, cents per pound.....	6
Zinc-dust, cents per pound.....	9

EASTERN METAL MARKET

(By wire from New York)

August 29.—Copper is inactive and lower. Lead is quiet but firm. Zinc is dull but easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 floc) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE PRICE OF LIBERTY BONDS

Richard H. Tingley, writing in 'American Industries', sums up the situation in relation to the holding of Liberty bonds that certificate seem to be refunding themselves in a certain way, according to calculations, as they will now purchase three or four times the amount of any commodity they could buy in the year 1917. He says:

"A very general feeling of dissatisfaction exists in the public mind at the present status of the Liberty and Victory Bonds. Issued under the compelling emergency of war and subscribed to at par by more than twenty million people under the hurrah of enthusiasm and intensive campaigning, the situation has since been transformed from a patriotic to an economic problem. Holders of these various issues have seen their apparent value gradually fade away and are frankly disappointed. An impression prevails that the Government should do something to restore the value of these bonds and many suggestions have been made looking to this end—all having in mind some form of refunding the several issues into a single long-term bond bearing a higher rate of interest.

"One of the simplest and apparently most reasonable suggestions offered is that a United States Sinking Fund Bond bearing 5% interest and maturing 100 years hence will solve the question. The interest rate might appear high for a nation with the highest credit on earth, but it is contended that such a bond will command a par price at once in the market and that the burden of amortization will be distributed over several generations—as it ought to be. This plan has never yet gone beyond the bare suggestion and the details of working it out would be annoying, for the several issues command each a different market price today—and will on any day.

"But why is any refunding operation necessary? The chief cause of complaint is that none of the bonds are worth in dollars as much as when they were purchased by the original holders. They have all depreciated in dollars value anywhere from 3% to 13%. But dollars have, in the meantime, appreciated in purchasing power of the things they will buy in a far greater proportion.

"The one hundred dollars you paid for your first 3½% Liberty Bond in June 1917 would have bought, if you had used the money for that purpose instead, only 333 pounds of copper at the then inflated price of that metal. Today, however, June 1921, even at the present depreciated money value of this bond (\$88.00), and the depreciated price of copper, you could buy 738 pounds—more than double the old amount. Following the same reasoning you might now buy 148 bushels of corn instead of 53 in 1917; or 1772 pounds of lead instead of 1000; or 98 pounds of wool instead of 67; or 738 pounds of rubber instead of 143—the purchasing power of your \$100 bond in terms of rubber has increased more than five times. And so on down the list. The same story would be told if the list of commodities were extended to cover almost every essential and non-essential. Why then talk of refunding these issues on a higher rate of interest under any plan? No one questions the ability of the United States to pay the principal and interest when due, and in the meantime, there would appear to be no real cause for complaint. Your bonds are worth more than when you bought them."

MONEY AND EXCHANGE

Foreign quotations on August 30 are as follows:

Sterling, dollars:	Cable	3.71½
	Demand	3.72½
Franc, cents:	Cable	7.87
	Demand	7.89
Lira, cents:	Demand	4.39
Mark, cents		1.21

Eastern Metal Market

New York, August 24.

There is no activity in most of the markets; mid-summer dullness prevails.

Buying of copper is still light, but prices are steady.

Consumers have been fairly active in the tin market.

Demand for lead is reported as steady and prices are firm.

Improvement in the zinc market has not set in and prices are a little softer.

Antimony is nominally unchanged.

IRON AND STEEL

The hope of the steel trade that autumn will bring a noticeable increase in buying amounts to something less than confidence as yet, but there are indications of slowly expanding demand for some forms of finished steel, says 'The Iron Age'. The best ground for better expectations is an increase in the number of orders coupled with a more urgent call for early delivery. Producers of steel see more signs of the using up of stocks that have long stood between them and anything more than a hand-to-mouth operation, and are encouraged to look for a gradual decrease in the scale of their losses. The rate of steel-ingot production is slightly larger this week at several important plants. Central Western mills find more activity in automobile steel than in any other direction. The market for sheet metal is more active, some buyers making their first purchases in months.

The week has been an outstanding one in fabricated steel. Upward of 12,000 tons was placed and nearly 20,000 has been added to active pending projects, not including 14,000 tons for the Federal Reserve Bank in New York. Railroad bridge and building work is conspicuous by its absence.

The pig-iron market has held the improvement of last week, considerable sales being reported at 50c., or more, above recent low prices in some districts, while other business was closed at prices quoted a fortnight ago.

COPPER

Sellers report almost no improvement. Interests which are willing to meet the prevailing demand, light as it is, at 11.75c., New York, or 12c., delivered, for electrolytic copper for early delivery, report a fair business but it is light at the best. It is believed that consumers are gradually depleting stocks with the manifestly better demand that is slowly appearing and that buying will be necessary soon. It is felt that the market has reached bottom and that the metal is a good buy at present. Foreign demand is fair with Japan a consistent purchaser. In recent weeks several thousand tons has been sold to that country and it is reported that Japanese interests are expecting to sell considerable copper wire for Far Eastern hydro-electric development. The Lake copper market is nominal at 12c., New York.

TIN

This market has been the most active of any. In the past week a total of at least 500 tons has been sold, mostly future shipment Straits. Consumers have been the largest buyers. Most of this business, however, was done last Wednesday, August 17, but about 100 tons was sold on Saturday. On other days, including yesterday and Monday, the market has been dull and nominal. The price tendency has been firm and there has been little change on any day, spot Straits yesterday having been quoted at 26.12½c., New York, the same as a week ago. London prices yesterday were practically the same as a week ago. Arrivals thus far this month have been 1785 tons with 3055 tons reported afloat.

LEAD

A fairly steady business is reported by most sellers, consumers being the principal buyers. Prices are exceedingly firm at 4.40c., New York, and 4.25c., St. Louis. The leading interest has not changed its quotation of 4.40c., New York and St. Louis, for two months, this level having prevailed steadily since June 23.

ZINC

The market is slightly weaker at 4.15 to 4.20c., St. Louis, or an average of 4.17½c., which may be quoted as the market for prime Western for early delivery. The metal can be obtained for this price although not on a large scale, but there is no doubt but that the 4.20c., St. Louis, price has been shaded.

ANTIMONY

The market is nominally unchanged at 4.50c., New York, duty paid, for wholesale lots for early delivery. It is felt by one seller that the market has reached bottom.

ALUMINUM

There has been no change. The leading interest quotes virgin metal, 98 to 99% pure, at 24.50c. per pound, f.o.b. plant, in wholesale lots for early delivery. The same grade from importers is available at 19 to 20c. per pound, New York.

ORES

Tungsten: The market is quiet and nominal at unchanged prices with the minimum at \$3 per unit in regular concentrate.

Ferro-tungsten can be purchased at 48 to 58c. per pound of contained tungsten in lump form, guaranteed as to quality.

Molybdenum: There is no demand and quotations are nominal at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: Absolute stagnation prevails and quotations for high-grade foreign ore are nominal at 20c. per unit, seaboard. Importations have taken a decided slump, having been only 5028 tons in July as against 18,447 tons in July, 1920, and over 60,000 tons per month early this year. Total imports for the first seven months have been 297,403 tons against 234,989 tons to August 1, 1920.

Iron-Manganese Alloys: The market for ferro-manganese is firm at \$65, seaboard, for the British alloy and \$70, delivered, for the American. Persistent rumors that less than these prices from first hands can be done are impossible of confirmation. British sellers say they cannot sell under the price named. Demand consists of 200 to 300 tons from a Middle Western consumer besides smaller lots.

Spiegeleisen, 20%, is firmly held at \$26, furnace, but inquiry is light.

Ferro-silicon: Demand for carload lots is all that is reported, for which a minimum of \$65 per ton, delivered, is reported as the bottom.

Many people will be surprised to be told that on the average of 20 railroad stocks there has been practically no net change in price during the last year. In the middle of August 1920 the average price of the 20 railroad stocks most commonly used to measure market movements was about 73 and it is now about 72. The investor who bought railroad stocks a year ago would not have suffered as he would have almost certainly done if he had held industrial stocks.

Current Prices of Commodities

The figures given on this page represent the regular current price, at the time of our going to press, to industrial buyers of standard commodities in small wholesale lots on San Francisco Bay. They should not be construed as being quotations nor as being either the lowest or the highest price; they are given rather as a guide by which to follow the trend of the market or to estimate the approximate cost of materials and supplies.

Bars, steel, square, cold-rolled, per 100 lb.	6.75
Pipe, wrought-iron, black, standard, 1 1/2-in., per 100 ft.	13.30
" " " " galvanized " " "	16.70
" " " " black " 4-in. " " "	58.00
" " " " extra strong " " "	113.75
Shafting, cold-rolled (2 1/4 to 3-in. base) " " "	5.50

HOISTING ROPE

Discounts for delivery from Pacific Coast stocks are: cast-steel, 22 1/2%; extra strong cast-steel, 30%; plow-steel, 35%; blue-centre steel, 20%. The following illustrations indicate the net price for each kind of rope, in standard, 6-strand, 19-wire, 1-in. rope.	
Blue-centre rope, per foot.	0.40
Cast-steel rope, per foot.	0.24
" " " " extra strong, per foot.	0.26
Plow-steel rope, per foot.	0.28

LUMBER

The figures given are subject to variation, depending upon the size and length. A charge for cartage is also to be added. Prices are furnished by Van Arsdale, Harris Co.	
Fir, No. 2 clear and better, 1 to 2 in. thick, up to 16 in. wide, per thousand feet (M)	80.00
Fir, common, base price, per M.	28.00
Fir, common, 6 by 6-in. up to 12 by 12-in., per M.	34.00
Redwood, rough merchantable, 1 to 4 in. thick, per M.	45.00 and 50.00
" " " " clear, 1 to 2 in. thick, up to 12 in. wide, per M.	90.00
Spruce, 'B' and better, 1 to 2 in. thick, up to 16 in. wide, per M.	80.00
Sugar-pine, No. 1 and 2 clear, 2 in. thick, up to 16 in. wide, per M.	200.00
White pine " " " "	150.00

MISCELLANEOUS

Air-hose, 1-in., 5-ply, plain, per foot.	0.48 to 0.65
Candles, 'Granite' mining, 6-16-40, 10-case lots, per case.	0.40
Carbide, in 100-lb. cans, per can.	7.75
Cotton waste, best grade, per 100 lb.	14.00
Diamonds for drilling, according to size, per carat.	50.00 to 75.00
Manila rope, grade 1, per pound.	0.15
" " " " 2 (standard), per pound.	0.14
Packing, flax, per pound.	0.33 to 0.85
" " " " sheet " " "	0.25 to 1.00
" " " " steam or water, first grade, per pound.	0.90
Silex lining, crated, per long ton.	35.00
Tube-mill pebbles, Danish, selected (in bags), per long ton.	30.00
Zinc-dust, in 250-lb. boxes, per 100 lb.	9.00
" " " " sheet, 36 in. by 84 in., No. 9 gauge, in ton lots, per 100 lb.	14.85

PORTLAND CEMENT, LIME, ETC.

Fire-brick, clay, per 1000, in carload lots.	60.70
Fire-clay, in bags, per ton.	18.00
Lime, lump, in barrels, per barrel of 180 lb.	3.25
Portland cement, in bags, per barrel of 380 lb.	4.20
Allowance of 15c. for bags returned in good condition.	
Portland cement, in barrels, per barrel of 400 lb.	5.50
A deduction of 50c. per barrel is made on lime and cement when sold in carload lots.	

ORES AND MINERALS

The following prices represent approximately what can be obtained for the products indicated delivered at points on San Francisco Bay. These, of course, vary widely with the grade and purity of the ores. The present stagnant condition of the market makes many of the quotations purely nominal; most of the ores can be purchased at these prices, but it should be understood that it is not easy for the producer to market them at this time.

Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per %	00c.
Asbestos (crystalline), according to length of fibre, per ton.	\$20 to \$2500
Barite, white and free of iron (cerulite), per ton.	5 to 10
Bismuth ore, not less than 20% Bi, per % Bi.	12
Feldspar, crude, lump, free of iron, per ton.	5 to 10
Fluorspar, 85% calcium fluoride, per ton.	15 to 20
Fuller's earth, ground to pass 80-mesh, per ton.	5 to 10
Graphite, crystalline, per pound.	3c. to 7c.
Magnesite, calcined, per ton.	25 to 35
Manganese ore, less than 0.75% Fe; less than 0% SiO ₂ , per ton	25 to 30
Mica, according to size, cleanness, and cleavage, per pound.	1 to 8
Molybdenite, not less than 85% free of copper, per % MoS ₂ .	8 to 12
Ochre, according to strength, crude, per ton.	8 to 15
Sulphur, 99.5% pure, only trace of As and Se, per ton.	15 to 18
Talc, lump, white, per ton.	7.50 to 10
Tin ore, not less than 60% Sn, per % Sn.	5
Tungsten ore, not less than 65% WO ₃ , per % WO ₃ .	2.75 to 3.00

T. A. RICKARD, Editor

NOW that the Mexican Supreme Court has decided that the Constitution of 1917 is not retroactive, and has enjoined the Executive from confiscating foreign oil property acquired before May of that year, it is expected that a way will be found for arriving at such a friendly settlement between Mexico and the United States as will lead to recognition of the Mexican government by the Administration at Washington. We hope so.

PROSPECTORS generally appear to dislike the proposed revision of the mining law, and mining engineers seem unwilling to defend it. The bill to codify and revise the mining laws of the United States has been introduced in the House of Representatives by Mr. Samuel S. Arentz, of Nevada. We happen to know that he is a subscriber to our paper and that therefore any criticisms we publish will be seen and considered by him. Mr. Arentz invites objections, criticisms, and suggestions, as it is his earnest desire that the proposed legislation shall be to the enduring benefit of the mining industry.

AMONG the valuable publications issued by the U. S. Geological Survey we esteem none higher than the 'Suggestions to Authors', by Mr. George McLane Wood, editor to the Survey. When the first edition of this useful little book appeared in 1888, we greeted it 'with cheers', as it were, and recommended it to the members of our profession, more particularly to the mining geologists, to whom it makes personal appeal. A fresh imprint has just been issued and we note that "additional copies may be procured from the Superintendent of Public Documents, Government Printing Office, Washington, D. C., at 15 cents per copy". *Verbum sap.*

FROM time to time the world is informed that somebody has re-discovered the lost art of tempering copper, making the metal hard enough for cutting other metals. The latest story is that the United States Steel Corporation has paid a million dollars to an inventor for his formula. This has been denied by Judge Gary, the chairman of the Corporation. It has been assumed by many that the ancients knew how to temper copper, whereas the fact is that the copper they made was harder only because it was impure. The 'art' of tempering copper never existed. Every once in a while some blacksmith comes forward with a claim to the re-discovery, but it is a mistake on his part, and sometimes on the part

of his backers. The alloys used for manufacturing modern high-speed tool-steel are far superior to anything that could result from the tempering of copper, and incomparably cheaper. The canard deserves a quietus.

DISARMAMENT is nothing new; all that is needed is a broader application of the principle. Some time this month a Peace Portal across the Pacific Highway will be dedicated at the boundary of the United States and Canada. That the two great English-speaking neighbors, divided only by an unfortified frontier, can live in harmony for a hundred years or more augurs well for disarmament on a larger scale. If the United States and Great Britain can come to a complete understanding on this point, the other nations of the world must follow suit. No revival of industrial or national prosperity is possible until world disarmament is an accomplished fact.

IN its monthly review of general industrial conditions, the Guarantee Trust Company says: "In any long view of the future, aid for the restoration and stimulation of world markets would be far more to the advantage of the United States than a selfish and short-sighted drawing away from foreign difficulties. To us it is plainly a mistaken belief that to wall-in our industries behind a tariff will cause them to flourish. As imports are excluded the cost of living would not have the wholesome corrective of reasonable foreign competition and, further, the loss to our merchant marine would surely have its reaction upon taxation." With this we agree. Incidentally, we may mention that the gentlemen of the Guarantee Trust Company of New York are neither philanthropists nor Sunday-school teachers, but hard-headed and patriotic men of business.

ANCHORAGE, the terminus of the Alaskan central railroad from the coast to Fairbanks, is being mentioned in the daily press as the scene of recent gold discoveries, said to have been made in the course of grading for the railroad. This is *à la mode de* Cobalt, and we hope it will prove as important as the discoveries that led to the widespread development of Ontario. We would be delighted to have these reports confirmed, for the opening of a new goldfield in Alaska would be the best possible thing for mining at this time. Meanwhile we are sceptical, because the accounts lack verisimilitude. The latest 'Associated Press' dispatch says that "many

strikes have been made in the rock-cuts blasted out of the precipitous walls of the Turnagain Arm division of the United States railway between Seward and Anchorage". It is asserted that "values ranging around \$25 per ton were found in veins twenty odd feet in width". This is journalese in place of the simple statement that an assay of \$25 has been obtained on a sample taken from lode-matter 20 feet wide. As one swallow does not make a summer, so one good assay does not turn rock into 'ore'. Again, it is stated that "while some veins show free gold, the major portion of them indicate what is known as cyaniding ores, necessitating concentration". It would be well if the 'Associated Press' selected as its representative in a mining region somebody who knows something about mining and milling; who knew, for example, the difference between cyanidation and concentration, between magnetic and magmatic, between cyanide and syenite, between alaskite and holdmetite.

THE extended use of concrete as a lining in tunnels and in mine openings is indicated by the construction recently completed by the Southern Pacific Company in the Tehachapi mountains. The railroad was built in 1876; 40 years afterward it was evident that the increase in traffic was such that the enlargement of the tunnels was imperatively necessary. Much trouble had been caused during the intervening time by fire and caving; and heavy losses were incurred. This particular stretch of railroad, 48 miles long, is one of the busiest single-track lines in the country; it is operated jointly by the Southern Pacific Company and by the Atchafson, Topeka & Santa Fe Railway; it runs from the floor of the San Joaquin valley to the summit of the Tehachapi mountains. In the busiest time of the year as many as 87 daily trains have been operated over the section, and as many as 1287 freight-cars; the daily schedule is 14 passenger trains and 8 freight trains. The tunnels, of which there are 18, were of small bore, except for a section of about 1000 feet in solid rock, and were lined with timber. In 1916 it was decided to enlarge them to a minimum horizontal section of 16 feet on the tangent and 17 feet on the curve, with a minimum overhead clearance of 22 feet. The adoption of reinforced concrete throughout provided a solution of the problem of tunnel fires and caving. The pneumatic method of construction was used, whereby steel frames, 20 feet long, were erected on tracks. These maintained the lining in position until it was set, the concrete being delivered from a montejus to the space above and around the frame by means of compressed air. When a section was complete, the frame was moved forward along the tunnel, and the operation repeated. When the members of the operating staff had become accustomed to the work, a rate of progress that amounted to 100 feet per week was maintained. About 6000 feet of tunnels has now been lined, the operations involving the use of 110,000 sacks of cement, 1,500,000 linear feet of reinforcing steel, and 45,000 tons of aggregate. The value of permanent work of such a nature cannot be over-estimated.
